Abstract

Incivility refers to behaviors that violate collective norms and disrupt cooperation within the political process. Although large-scale online data and automated techniques have enabled the quantitative analysis of uncivil discourse, prior research has predominantly focused on impoliteness or toxicity, often overlooking other behaviors that undermine democratic values. To address this gap, we propose a multidimensional conceptual framework encompassing Impoliteness (IMP), Physical Harm and Violent Political Rhetoric (PHAVPR), Hate Speech and Stereotyping (HSST), and Threats to Democratic Institutions and Values (THREAT). Using this framework, we measure the spread of online political incivility in Brazil using approximately 5 million tweets posted by 2,307 political influencers during the 2022 Brazilian general election. Through statistical modeling and network analysis, we examine the dynamics of uncivil posts at different election stages, identify key disseminators and audiences, and explore the mechanisms driving the spread of uncivil information online. Our findings indicate that impoliteness is more likely to surge during election campaigns. In contrast, the other dimensions of incivility are often triggered by specific violent events. Moreover, we find that left-aligned individual influencers are the primary disseminators of online incivility in the Brazilian Twitter/X sphere and that they disseminate not only direct incivility but also indirect incivility when discussing or opposing incivility expressed by others. They relay those content from politicians, media agents, and individuals to reach broader audiences, revealing a diffusion pattern mixing the direct and two-step flows of communication theory. This study offers new insights into the multidimensional nature of incivility in Brazilian politics and provides a conceptual framework that can be extended to other political contexts.

Keywords: Multidimensional Incivility | Brazilian Politics | NLP | Social Network | Social Media

1 Introduction

Social media platforms have enabled diverse political influencers—such as politicians, media outlets, journalists, and ordinary users—to produce political content and shape public opinion [22]. While social media creates an environment for ordinary users to receive political information by bypassing traditional information sources, it also provides a space for uncivil expressions and hostile attacks to unfold [26]. Previous studies have shown evidence that such uncivil behavior might reduce public political trust [48], increase polarization among groups [35], and even lead to offline violence [17]. However, incivility is not always detrimental to democracy. Studies have also shown that incivility can also draw public attention [49], encourage political participation [6], and assist marginalized groups in expressing disagreement [38]. Therefore, it is neither possible nor necessarily desirable to remove all uncivil content online [41]. This realization motivates many studies, including this one, to achieve a deeper understanding of incivility by measuring it through more nuanced categories [5, 18, 46, 51, 60].

Incivility has been previously subcategorized into behaviors such as name-calling, aspersion, vulgarity, hyperbole, and shouting/screaming notation, which involve disrespectful or rude actions towards individuals or groups [10, 47, 50]. Others argue that certain discourses may remain polite yet still be uncivil if only they violate collective norms established, such as discourse that undermines democratic values [18, 51, 56]. While many discussions about the multidimensional concept of incivility exist [5, 46], there remains a lack

of relevant measurements and deeper understanding regarding who the main disseminators and audiences are and how such content spreads among users.

In this study, we propose a multidimensional conceptual framework that synthesizes prior research, classifying incivility based on violations of collective norms such as social norms and democratic norms, along with four specific taxonomies: Impoliteness (IMP), Physical Harm and Violent Political Rhetoric (PHAVPR), Hate Speech and Stereotyping (HSST), and Threats to Democratic Institutions and Values (THREAT). We then develop algorithms to facilitate the detection of these four dimensions of incivility.

Our ultimate goal is threefold: first, to understand the dynamics of different dimensions of incivility online, focusing on trends and key events. Second, to identify the main disseminators and audiences of incivility. Finally, to investigate the mechanisms of information flow for online incivility. In summary, this study is organized around the following research questions:

RQ1: How can we construct multidimensional incivility, and how can we measure it?

RQ2: When do different dimensions of online incivility emerge?

RQ3: Who are the main disseminators and audiences of different dimensions of online incivility?

RQ4: In what ways do political influencers disseminate uncivil content to ordinary audiences?

To address these questions, we combine national survey data collected during the 2022 Brazilian Presidential Election—held in two rounds on October 2 (first round) and October 30 (runoff)—with 5 million posts from 2,307 Brazilian political influencers on Twitter (now X) followed by survey participants. First, for RQ1, we develop a codebook that distinguishes incivility dimensions based on violations of different collective norms and train human coders for manual annotation. We then develop multiple binary classifiers using pre-trained sentence transformers and apply them for classification. For RQ2, we employ non-parametric modeling to fit the trends in the frequency of uncivil content and detect key events. For RQ3, we manually annotate political influencers into three account types—Politician, Media, and Individual—and categorize their socio-political identities. We investigate their distributions across incivility dimensions. Finally, for RQ4, we construct an incivility network using following and retweeting relations. We detect three network motifs representing different information flow mechanisms among survey users and political influencers. We also use centrality measures in retweet networks of uncivil messages to identify the main original creators of incivility.

Our analyses show that scores for all dimensions of incivility peak during heated events and decrease subsequently. However, IMP primarily breaks out before the election days. PHAVPR, HSST, and THREAT mainly emerge during or after events of extreme-right violence. Second, a deeper dive into the disseminators reveals that left-aligned individual political influencers constitute the majority of those disseminating incivility in the Brazilian Twitter/X sphere. Third, individual political influencers not only disseminate uncivil information by retweeting politicians, media agents, and other individual accounts but also generate a large amount of original uncivil texts. We find that the main mechanism of incivility delivery is a direct flow from political influencers to their followers. However, as influencers tend to retweet other influencers with shared followers, a mix of direct and indirect information delivery, rather than the traditional two-step flow of information, is more prevalent than expected at random.

While previous studies suggest that extremist right-wing groups predominantly instigate offline political violence, such as the attack of the U.S. Capitol after the 2020 election and of the Brazilian Congress after the 2023 election, the evidence from Brazilian Twitter/X space reveals a different dynamic: left-aligned individuals emerge as the primary drivers of uncivil information. On close inspection, many left-aligned users appear to be primarily responding to the uncivil behavior of their outgroup. This finding has two key implications. First, it underscores the existence of a feedback loop that exacerbates polarized tensions between political groups. Second, it highlights the efforts of online users to draw public attention to acts of violence. Future research should replicate this study across different time periods, countries, and platforms, and further differentiate direct and indirect mentions of incivility.

2 Related Work

2.1 Online Incivility as a Multidimensional Concept

Incivility broadly refers to behaviors that violate collective norms and hinder cooperation among social and political agents [60]. Related concepts include impoliteness, intolerance, and toxicity. Impoliteness focuses on disrespectful communication behaviors, while intolerance—referred to by different names in various literature and defined here following [56]—highlights violations of democratic values in discourse [51, 56]. Toxicity overlaps with both concepts, emphasizing harmful elements directed at individuals or groups [2, 9, 58]. To clarify these relationships, we provide a conceptual illustration in Fig. 1

The conceptualization of (political) incivility has long been a subject of debate. For example, [19] and [10] focus on rude or disrespectful behaviors targeting individuals or groups, namely impoliteness. In contrast, [51] defines incivility as behaviors that undermine democratic values, aligning closely with intolerance as described by [56].

Recent literature has integrated these perspectives, proposing multidimensional frameworks for a more nuanced understanding of incivility [5, 18, 46]. For example, [46] distinguishes between personal-level and public-level incivility, while [5] categorizes incivility into dimensions such as impoliteness, individual delegitimization, and institutional delegitimization. Our approach summarizes and provides conceptual clarity to these various works. It stems from the collective norms that incivility violates.¹

Figure 1: Multi-dimensional conceptualization of incivility and its related concepts. Incivility is a composition of toxicity and intolerance.

2.2 Quantifying Online Incivility

The widespread availability of large-scale data and recent advances in machine-learning techniques have enabled the automatic detection of online incivility. Among the most commonly measured categories are toxicity and hate speech [3, 20, 57]. For instance, Google and Jigsaw developed the Perspective API, which uses machine learning to score the toxicity of input text. Similarly, hate speech, defined as “abusive speech targeting specific group characteristics, such as ethnicity, religion, or gender”, has been tackled using various automated methods, including TF-IDF [1], lexicon-based approaches [20], deep learning methods [3], and hybrid approaches [57].

Hate speech has also been distinguished from other impolite categories, such as offensive, abusive, aggressive, and cyberbullying language [14]. At a more granular level, hate speech has been subcategorized into types such as religion-based, sexist, racist, homophobic, and other forms of hate [21]. In computer science, most models for detecting hate speech are evaluated on generalized datasets [13, 42, 45]. However, researchers in other domains often fine-tune models for downstream applications for specific tasks and develop custom classifiers tailored to their unique requirements e.g., [16, 59, 62].

To predict uncivil categories, previous studies have utilized logistic regression models [62], neural networks [39], and more recently, pre-trained language models such as BERT and RoBERTa [12, 18]. For shorter social media texts, [53] introduced sentence transformers, which pool word embeddings into

¹The incivility dimensions in this work are part of the Swiss National Science Foundation (SNSF) project: *From Uncivil Disagreement to Political Unrest? A Cross-Platform & Cross-National Analysis of the Offline Consequences of Online Incivility*.

sentence-level representations to capture contextual meaning more effectively. However, even though classifiers for identifying toxicity and hate speech are common, classifiers targeting violations of democratic values, are rare. To the best of our knowledge, our work develops the most comprehensive classifiers, covering various dimensions of incivility.

2.3 Online Political Influencers and Multi-step Flow of Uncivil Information

As social media increasingly dominates communication, we have entered an era where “any person can theoretically build an audience and grow their influence” [22]. Online influencers are particularly effective in branding and marketing due to their authentic, celebrity-like connections with broad audiences. This study focuses on political influencers, defined as influential accounts that are dedicated to promoting political stances, social identities, or preferred candidates through their content [54].

Prior research identifies three key criteria for classifying political influencers: (1) their content must be political, either aggregating general political information [61] or reflecting specific political or social identities [65]; (2) their influence can be reflected by proxies such as follower counts, diffusion cascades, and potential post-earnings [4]; and (3) they leverage platform-specific features to promote content within distinct social media ecosystems [24]. Here, we identify political influencers from keywords self-disclosed in their profiles and their follower counts.

Political influencers broadly include politicians, media outlets, journalists, and any influential individuals [30, 37, 40, 43]. Among these, individual influencers play an increasingly significant role in disseminating online information [31, 64]. These individual influencers are usually partisans, candidate supporters, and members of marginalized groups such as religious minorities, women, LGBTQ individuals, and ethnic communities.

The two-step flow of communication theory highlights the role of individual opinion leaders as intermediaries, relaying information from mass media to the broader audience [32, 33]. Extensions of this model—such as horizontal two-step flows, where opinion leaders also generate their own content, and multi-step or mixed-flow frameworks, where information travels through various channels—help capture the greater complexity of modern communication. [27, 29, 63]. Therefore, in this work, we test not only two-step information flow but also direct flow and mixed flow. Social media platforms now allow researchers to approximate these flows using platform-specific interactions. For instance, on Twitter/X, following relationships often represent direct information flows, while retweets may reflect two-step flow processes [25, 55, 64].

3 Data and Methods

3.1 Data Collection and Socio-political Identity Annotation

During the 2022 Brazilian presidential election—held on October 2 (first round) and October 30 (runoff), NetQuest, an international survey company, conducted a national survey. The survey involves 1,018 respondents who are representatively sampled by gender and region, with targeted income distribution nationwide. Data were collected through Netquest’s proprietary online panel using stratified quota sampling to ensure demographic representativeness. Panelists were recruited via double opt-in procedures and completed the survey online in exchange for incentives.² Respondents were asked for consent to provide their Twitter handles. Of the 1,018 respondents, 403 consented, and 271 were verified as existing Twitter accounts, accounting for 26.62% of the total panel.

We collect the Twitter accounts followed by the 271 survey participants using the Twitter API, resulting in 57,645 followers and 73,755 following pairs. We then identify political influencers based on three criteria: 1) having at least 1,000 followers, 2) profile description displaying politics-related content [23, 34], and 3) being located in Brazil (see Section 2 in Appendix for more details).

Ultimately, we obtain data from 204 survey participants, 2,307 political influencers, and 4,107 following pairs. Additionally, we collect tweets posted or retweeted by political influencers from 1st September 2022 to 1st February 2023, resulting in 5.22 million tweets.

To evaluate the representativeness of the 204 survey sample, we compare several demographic variables, including Age, Gender, Ethnic, Religion, Income, and Education, between the 204 sample and the full sur-

²For more details, please refer to the NetQuest Panel Book: <https://www.netquest.com/en/panel>.

vey sample. Pearson’s chi-squared tests (for categorical variables) and Mann–Whitney U tests (for discrete variables) of the demographic variables between the 204 sample and the 1,018 respondents do not reject the null hypothesis that both samples are drawn from the same distribution at a significance level of 5% (see Fig.1 in Appendix). Fig.2 in Appendix further demonstrates that the ideological position of the 204 sample has no strong bias toward any particular leaning. We then examine how this representative survey sample is exposed to incivility disseminated by the political influencers they follow.

We manually annotate the socio-political identities of uncivil political influencers. A human coder who is familiar with Brazilian politics first classifies each influencer by Account Type—categorizing them as politicians, media (including media outlets and journalists), or individual influencers. The coder further annotates their socio-political identities based on three dimensions: Ideological Position (Left/Right/Center), Campaign Support (Lula/Bolsonaro), and Social Identity (including Women—particularly in the context of advocating for women’s rights, Religious, Black, or LGBTQ). The choice of social identity categories is informed by a manual review of 2,000 randomly sampled profiles. A codebook detailing how these categories are identified is provided in Section 3 of the Appendix. These annotations are based on self-disclosed information from users’ Twitter/X profiles.

3.2 Multidimension Construction and Automatic Classification of Uncivil Texts

We address RQ1 by using incivility dimensions that represent the four collective norm violations, as predefined in our codebook (see Section 4 in Appendix). First, impoliteness is a typical dimension representing the violation of etiquette rules [52]. Physical harm and violent political rhetoric extend beyond the realm of etiquette and signify violations of general norm of non-violence [44]. Additionally, we consider behaviors that breach social equality & non-discrimination, and democratic norms. Hate speech and stereotyping are typical forms of uncivil language that violate social equality and non-discrimination, while violations of democratic norms involve political behaviors discrediting democratic institutions or values.

We develop four supervised learning classifiers to identify multidimensional incivility, trained on a Brazilian corpus collected from multiple social media platforms during the 2022 Brazilian presidential election, including Twitter/X, Facebook, YouTube, Telegram, etc. The full list of data sources is provided in Section 4 of the Appendix.

We select samples from this corpus for manual annotation by two human coders who are familiar with Brazilian politics and fluent in the Brazilian language. To ensure consistency, we conduct a pilot coding procedure involving the two coders and researchers. First, approximately 30 samples for each incivility dimension are annotated independently by the two coders. Second, a meeting is held between the researchers and the coders to discuss the samples with disagreements. Third, a final decision is made on the coding guidelines, and the process is repeated until the majority of samples are consistently agreed upon by both coders. Through five rounds of pilot annotations, we refine definitions to achieve consensus and clarity. Finally, each coder is assigned with 500 samples per dimension for formal annotation. There are 100 overlapping samples between the two coders’ annotation sets used to assess inter-coder reliability. Upon agreement, we obtain a total of 900 annotated samples per dimension that serve as the initial training data for the supervised classifiers.

The initial annotation shows that positive (uncivil) samples of four dimensions of incivility accounts for 26.66%, 1.52%, 6.29%, 6.30% of the overall datasets respectively. To address the scarcity of positive samples, we employ an active learning strategy combining human annotation and automated modeling (see Fig. 2). Here is a detailed description of the three steps of this process:

Step 1: Automatic Pre-selection. We create an initial training dataset by combining posts flagged as toxic by the Perspective API with stratified random samples. Two coders who are familiar with Brazilian politics and Brazilian language annotate this dataset.

Step 2: Semantic Vector Projection. Annotated posts are mapped into a semantic vector space using pre-trained SentenceTransformer embeddings [53]. The centroid of the positive class is calculated as the mean of its document-level vectors. Unlabeled posts are compared to this centroid using cosine similarity to identify potential positive samples.

Step 3: Iterative Annotation. Unlabeled posts with high similarity to the positive centroid are sampled for manual annotation in a second round. To avoid potential bias, we also include posts with lower similarity, but not too far from the positive centroid. Concurrently, an initial classifier is trained on the limited data and used to filter unlabeled posts for additional positive examples. Annotated posts with agreement between

coders are added to the training data. This approach enhances the diversity of positive cases.

Figure 2: Procedure of generating positive (uncivil) samples with active learning.

3.3 Investigating Dynamics of Mutil-dimensional Incivility Occurrence

This section investigates the trends and events dynamics of incivility at various stages of the election, as questioned in RQ2. The trends refer to the upward and downward changes over time, while the events-level dynamics focus on outlining spikes on specific dates, often corresponding to the emergence of particular events. We utilize smoothing spline, a non-parametric regression method, to fit the trends in the frequency of uncivil posts and examine the outliers across various dimensions of incivility.

The loss function of the smoothing spline is given by $\sum_{i=1}^n (y_i - f(x_i))^2 + \lambda \int f''(x)^2 dx$, where $f(x)$ represents the smoothing spline function and n is the number of observations. The left-hand term measures the goodness-of-fit, and the right-hand term is the roughness penalty. The smoothing parameter λ controls the trade-off between the two terms. First, we set the parameter λ to 0.6 to examine the trending patterns. We choose this value based on manual testing to ensure sufficient smoothness for capturing the trends. Second, to detect outliers representing unexpected events, we choose λ based on generalized cross-validation (GCV), which minimizes the predictive error [8].

We then identify the outliers that most significantly influence the model fitting using Cook’s distance, which quantifies the influence of individual data points on the estimated regression coefficients [11, 15]. Unlike the trends of incivility’s general ups and downs, outliers indicate specific dates when uncivil content exhibits substantial spikes.

3.4 Investigating Disseminators and Audience of Mutil-dimensional Incivility

To address RQ3, we analyze the disseminators of incivility and their audiences (survey users) across multiple dimensions. We first examine the number of survey users exposed to incivility at varying density levels. Incivility density is defined as the ratio of uncivil posts to the total number of posts by influencers. The exposed users are counted as the sum of direct followers and indirect retweets receivers of uncivil messages. To assess how incivility density influences exposure counts, we apply a quantile regression model [7]. Unlike traditional linear regression, this model estimates conditional quantiles (e.g., median or other percentiles) of the response variable, making it well-suited for our data, given the wide range of exposed audience counts at each density level. Additionally, we calculate Jaccard similarity to measure the overlap of political influencers and the survey users exposed to them across quantiles and dimensions.

We then examine the specific identities of political influencers who post different ratios of incivility. Influencers are categorized into four quantiles, ranging from low to high incivility density. Their identities are analyzed across quantiles and dimensions based on manual annotation of profile descriptions. We use the G-test to assess differences in identity group distributions across incivility density levels and dimensions.

3.5 Investigating Mechanisms of Information Flow of Mutil-dimensional Incivility

Finally, we investigate how uncivil information is spread between political influencers and the survey audience (RQ4). To analyze the dissemination mechanisms of uncivil information, we construct a bipartite

network $G = (U, V, E)$, where U represents the set of ordinary followers, V denotes the set of political influencers, and E comprises edges indicating follower-influencer relationships. We then project this bipartite network onto the influencer set V , resulting in a unipartite network $G' = (V, F)$. In G' , an undirected edge $e_{ij} \in F$ between influencers v_i and v_j exists if they share common followers, with the edge weight corresponding to the number of shared followers. Additionally, we incorporate another set of directed edges, R , containing all the retweets done by the political influencers in V . An edge $r_{ij} \in R$ from v_i to v_j represents retweets of v_i by v_j , indicating the direction of the flow of information with a weight equal to the number of retweets. We also add a new set of nodes, V' , containing users who are retweeted by political influencers but are not in V , resulting in the retweet graph $G'' = (V \cup V', R)$. The resulting network is a multilayer graph, H , with one layer, G' , representing shared followers of political influencers and a second layer, G'' , capturing retweeting among them. Using the follower graph, G , and the multilayer graph H , we capture how survey users are exposed to uncivil content. This can happen either by being exposed to content created by an influencer they follow or when an influencer they follow retweets someone else. More precisely, we distinguish three distinct motifs of information flow from political influencers to survey respondents:

1. **Direct flow**: direct exposure to an original tweet, or a self-retweet, of a political influencer followed by a survey user.
2. **Two-step flow**: indirect exposure occurs when a political influencer followed by a survey participant retweets content from an account the participant does not follow.
3. **Mixed flow**: mix of direct and indirect exposure through a retweet of a political influencer, followed by a survey user, retweeting an account also followed by the survey user.

We note that the assumption above—that ordinary users are exposed to uncivil content solely through direct followership and indirect retweets—is a simplified proxy. In reality, users may also encounter such content through random browsing, private messages, or quotations that are not captured by our methods, meaning their actual exposure may differ from our estimates. Moreover, in the context of the two-step flow theory in social science, paraphrased content from opinion leaders may also be relevant, which requires more sophisticated strategies.

We show the three motifs in Fig. 3. To identify salient mechanisms, we calculate the Z -scores by comparing the observed motif counts with those obtained by randomizing the retweet edges using a directed configuration model. Additionally, to determine who utilizes these mechanisms, we analyze the identities of influencers within each motif and identify the leading creators of incivility using PageRank centrality.

Figure 3: Motifs of information flow mechanisms.

4 Results

4.1 Performance of Automatic Classification of Uncivil Texts

The related collective norms, dimensions, definitions, examples, and inter-coder reliability metrics of our automatic classification of uncivil texts are summarized in Tab. 1.

Model performance, evaluated using ten-fold cross-validation, is summarized in Tab. 2. We calculate the metrics by aggregating all predictions from each fold to help mitigate issues caused by class imbalance within individual folds. The weighted F1 scores across dimensions range from 78% to 93%, indicating good classification performance. The trained classifiers are subsequently applied to the remaining tweets of political influencers. To ensure reliable labeling, uncivil labels - "1" are assigned only when the predicted probabilities for the positive class are at least 0.7. The number of classified uncivil posts for each dimension is shown in Tab. 3.

Table 1: Summary of related norms, dimensions, definitions, examples, and inter-coder reliability statistics of incivility. Examples are selected from our Brazilian Twitter/X dataset. Both Gwet’s AC2 score and agreement are reported to assess inter-coder reliability.

Related Norm	Dimension	Definition	Example (translated)	Gwet’s AC2 Score/Agreement
Etiquette	Impoliteness (IMP)	Messages displaying rudeness or disrespect, often using offensive language directed at individuals or groups.	# Haven’t you gotten tired of the “biggest corruption scheme in history” yet? Litany of idiots.	0.78/0.85
Non-violence	Physical Harm and Violent Political Rhetoric (PHAVPR)	Messages threatening physical harm against individuals or groups, or promoting violence in political contexts.	# The Northeast also fights against the left!	0.93/0.93
Equality and non-discrimination	Hate Speech and Stereotyping (HSST)	Messages promoting hostility or discrimination against individuals or groups based on specific attributes, often referring to social identity groups.	# Bolsonaro supporters are stupid in terms of numbers, gender and degree.	0.90/0.91
Democratic norms	Threats to Democratic Institutions and Values (THREAT)	Messages undermining democratic procedures and institutions, the democratic state, and democratic values.	# The judiciary persecutes those who do not follow their rules...Our only hope is #SOSFFAA Salve O Brasil	0.92/0.92

Table 2: Cross-validation results of classification performance for the four uncivil dimensions.

Classifier Type	Dim	F1 _{Dim}	F1 _{non-Dim}	Weighted F1
Single	D_{IMP}	0.93	0.94	0.93
Ensemble	D_{PHAVPR}	0.65	0.91	0.86
Ensemble	D_{HSST}	0.76	0.79	0.78
Ensemble	D_{THREAT}	0.75	0.84	0.80

4.2 Different Dimensions of Incivility Break Out at Various Stages

Here we examine when during the Brazilian election campaign different dimensions of incivility appear (RQ2). The fitting lines in Fig. 4 illustrate the trends and key events for different dimensions of incivility during the election period. IMP shows a significant upward trend around the two election rounds and the Congress attack, with outliers highlighting key dates just before the first-round election (October 2, 2022) and the runoff election (October 30, 2022). PHAVPR exhibits pronounced activity during the Congress attack, with outliers pinpointing January 7 and 8, 2023, as significant dates. HSST, besides peaking during the two election rounds and the Congress attack, also shows a notable increase during the road and highway blockades, with December 13, 2022, identified as a key date. THREAT displays a macro trend with two major peaks: the run-off election (coinciding with the Brasília protest) and the Congress attack, with outliers on December 30, 2022, and January 8, 2023.

In summary, all dimensions of incivility surge around key events, but their magnitudes vary over time. IMP is most concentrated during the election rounds, suggesting its use in voter attraction and election-related strategies. In contrast, PHAVPR, HSST, and THREAT are more prevalent during violent offline events happening, reflecting their association with violence and unrest. Outlier detection further validates these patterns, highlighting distinct temporal dynamics across dimensions of incivility.

4.3 Dominant Disseminators Differ but Share Similar Identities Across Dimensions

This section identifies the main disseminators (political influencers) and audiences (survey users) of online uncivil messages (RQ3). First, disseminators are ranked by their ratio of uncivil posts to total posts, from low to high. Fig. 5 presents the distributions of exposed audiences, calculated as the sum of followers and retweet receivers of uncivil disseminators, across different levels of uncivil ratios. Quantile regression results (Tab. 4) reveal that for all dimensions except THREAT, the number of exposed audiences decreases as disseminators’ uncivil ratios increase. The correlation is strongest for IMP between the 0.25 and 0.9 quantiles, reaching a 5% significance level. For PHAVPR and HSST, significance is observed only at the median level. Conversely, for THREAT, the number of exposed audiences significantly increases at the 0.9 quantile as the incivility ratio rises. This suggests that more frequent uncivil posts do not necessarily attract larger audiences.

Table 3: Summary statistics of the classified dataset.

	D_{IMP}	D_{PHAVPR}	D_{HSST}	D_{THREAT}
N (Posts)	138,153	34,283	46,522	107,695
N (Influencers)	1,688	1,598	1,481	1,631
N (Followers)	199	200	198	200

Figure 4: Trends and event dynamics of four incivility dimensions—IMP, PHAVPR, HSST, and THREAT. The first and third columns show trends with smoothing splines ($\lambda=0.6$). Original data points with GCV smoothing splines and outliers (red dots) identified by Cook’s distance are in the second and fourth columns. Grey lines mark five key events: (1) First-round election, (2) Run-off election, (2) Brasilia protest, (3) Highway blockades, and (4) Congress attack.

Disseminators and their audiences are further divided into four quantile subgroups based on the disseminators’ uncivil ratio rankings for each incivility dimension. The average value of Jaccard similarity of disseminators across dimensions and quantiles demonstrates high dissimilarity (0.1035 ± 0.0707). However, their audiences exhibit substantial overlap across dimensions and quantiles (0.8827 ± 0.0460). This raises important questions about the identities of the main disseminators across dimensions and levels and why they attract similar audiences.

Table 4: Quantile regression results for exposure and incivility ratio across dimensions.

DIM	Q(0.1)	Q(0.25)	Q(0.5)	Q(0.75)	Q(0.9)
D_{IMP}	$-1.45 \cdot 10^{-6}$	-7.58^{**}	-29.51^{***}	-111.89^{***}	-250.97^{***}
D_{PHAVPR}	$-6.98 \cdot 10^{-6}$	-17.60^*	-56.54^{***}	-149.34	-136.11
D_{HSST}	$-3.78 \cdot 10^{-6}$	-11.04	-63.61^{**}	-263.59	-550.13^*
D_{THREAT}	$-1.06 \cdot 10^{-6}$	-2.03	-11.36	$-2.90 \cdot 10^{-7}$	222.90^{***}

We show the distributions of disseminator account types across incivility dimensions and quantiles of incivility ratios in Fig. 6. Accounts from individuals constitute the majority of political influencers across all dimensions: IMP (63.08%), PHAVPR (60.59%), HSST (66.39%), and THREAT (59.18%). For IMP and HSST, the proportion of individual accounts is larger, while the proportions of politicians and media accounts is smaller for higher levels of incivility ratio. Conversely, for PHAVPR, the proportion of individual accounts becomes smaller and the proportions of politicians and media agents larger for higher levels of incivility density. For THREAT, account type distributions remain relatively stable. The G-test statistics (Tab. 5) confirm significant differences in account type distributions at the 5% significance level for IMP, PHAVPR, and HSST, but not for THREAT.

The distribution of self-reported identities among individual accounts shows that left-aligned individuals, such as those with left-wing ideologies or supporting Lula, constitute a larger proportion of individual influencers across all dimensions: IMP (43.12%), PHAVPR (44.42%), HSST (43.54%), and THREAT (44.30%). In comparison, right-aligned individuals, such as those with right-wing ideologies or supporting Bolsonaro, account for smaller proportions: IMP (22.91%), PHAVPR (22.74%), HSST (24.06%), and THREAT (24.26%).

For IMP, the proportion of left-aligned individuals increases with incivility level. For PHAVPR, while there is no strictly ascending trend across quantiles, left-aligned individuals are significantly more prevalent

Figure 5: Kernel density estimate plot of the variation in survey audience’s exposure, measured by the total number of followers and retweet receivers of uncivil messages, as the ratio of uncivil posts (density) increases.

in the third and fourth quantiles than in the first and second. In contrast, for THREAT, the proportion of left-aligned individuals decreases as incivility levels rise, while HSST shows no significant changes. G-test statistics (Tab. 5) confirm significant differences at the 5% level for all dimensions except HSST.

Table 5: Results of the G-test for account types (AT) and individual identities (IE) across the four quantiles of uncivil density for each dimension.

Dimension (DIM)	G-test χ^2 (AT)	p -value (AT)
D_{IMP}	176.88	$1.56 \cdot 10^{-35}$
D_{PHAVPR}	59.54	$5.57 \cdot 10^{-11}$
D_{HSST}	130.58	$9.69 \cdot 10^{-26}$
D_{THREAT}	12.39	$5.38 \cdot 10^{-2}$
Dimension (DIM)	G-test χ^2 (IE)	p -value (IE)
D_{IMP}	115.02	$2.38 \cdot 10^{-2}$
D_{PHAVPR}	134.73	$3.72 \cdot 10^{-4}$
D_{HSST}	95.64	$1.81 \cdot 10^{-1}$
D_{THREAT}	148.10	$7.86 \cdot 10^{-6}$

4.4 Direct Information Flow Dominates in Uncivil Communication Online, whereas Mixed Information Flow is Significant

To understand the mechanisms of information flow responsible for the spread of uncivil content (RQ4), we investigate the motifs in the network of retweets and co-follow relations. We distinguish the three information flow motifs—direct flow, two-step flow, and mixed flow (see Fig. 3). The motif counts and Z -scores are presented in Tab. 6. Z -scores can only be computed for two steps and mixed flow, as the direct flow involves only one influencer and no retweet. Our results reveal that direct flow is the dominant pattern of diffusion of uncivil content, two-step flow is the second most prevalent, and mixed flow is the least prevalent. Interestingly, the Z -scores reveal that two-step flow motifs are significantly less prevalent, and mixed flow motifs are significantly more prevalent than in networks where retweets have been randomized. This shows that when political influencers retweet other accounts, they tend to favor accounts with whom they have shared followers. Therefore, survey users’ tendency to be subjected to the same uncivil content both directly and indirectly is higher than expected at random.

The account types of disseminators involved in these flow mechanisms are shown in Fig. 7. Across most dimensions and motifs, individual influencers play an important role in spreading uncivil information. They act both as intermediaries who retweet content from politicians and media (as shown in motif 2 and 3) and direct disseminators who create their own original uncivil posts (as shown in motif 1 and 3).

Overall, the mixed information flow emerges as the most significant mechanism for disseminating uncivil content, as compared with the randomized retweet configuration model. Further analysis of the

Figure 6: Distribution of account types and individual self-disclosed identities across quantiles of uncivil densities (q_1, q_2, q_3, q_4 , from low to high) and dimensions (IMP, PHAVPR, HSST, THREAT). Categories are ranked in descending order, and only those that cumulatively account for 80% of all individual identities are displayed.

socio-political identities of individual influencers in Mixed Flow motifs shows that over 80% of individuals retweeting uncivil messages from politicians, media, and other individuals are left-aligned users, such as those with left-wing ideologies or Lula supporters. This aligns with earlier findings highlighting the role of left-aligned individuals in transferring uncivil content from official political accounts to the public.

Additionally, we show the dominant creators of incivility, identified using PageRank centrality in retweet networks, in Tab. 7. Politicians are key creators of IMP messages, while media accounts, including outlets and journalists, dominate in producing THREAT messages. The creators of PHAVPR and HSST messages include a mix of politicians, media, and individual influencers. These results, alongside manual post-examinations, suggest that IMP is frequently used as a campaign strategy during elections, whereas dimensions like THREAT serve as denunciations of extremist right-wing behaviors.

5 Conclusion and Discussion

This study automatically detects four dimensions of incivility—IMP, PHAVPR, HSST, and THREAT—on Twitter/X during the 2022 Brazilian Presidential Election and analyzes their dynamics, disseminators and audience, and dissemination mechanisms. The analysis of post dynamics reveals that the four dimensions of incivility emerge at different stages. IMP primarily peaks on election days during political campaign. In contrast, PHAVPR, HSST, and THREAT are more prominent while violent events happening. An analysis of the disseminators' identities indicates that left-aligned individuals are more prominently involved in spreading uncivil information. They demonstrate a significant pattern of retweeting uncivil information from politicians, media, and other influential accounts, and share common audiences with the accounts they retweet. This indicates that a mixed information flow, rather than pure two-step information flow, is the

Table 6: The comparison of observed motifs with motifs in the randomized configuration model. Motifs 1–3 represent Direct Flow, Two-step Flow, and Mixed Flow. I denotes the number of motifs in the observed network. RM represents the average number of motifs in the randomized configuration model. RS represents the standard error of motifs in the randomized configuration model. The difference between observed motifs and random motifs is expressed using z-scores.

Figure 7: Histograms displaying the distribution of account types—Individual (I), Media (M), and Politician (P)—of uncivil disseminators across different information flow motifs and dimensions of incivility. The label (A, B) indicates an information flow from A to B, namely B retweets A.

significant mechanism for spreading uncivil content.

This finding contrasts with previous studies, which suggest that the right-wing exhibits more uncivil behavior during political campaigns e.g., [52]. A manual post-check of the uncivil posts made by left-aligned and right-aligned influencers revealed that, except for IMP, a large number of uncivil posts are indirect mentions of incivility, meaning that users are discussing or even opposing incivility expressed by others. This phenomenon is more prominent among left-aligned influencers. For instance, "they are shooting at Indigenous people in the streets (PHAVPR)", "I express my full solidarity with an official who was targeted by a misogynistic and cowardly political supporter (HSST)", "We are vigilant and monitoring all necessary measures to curb coup-related and anti-democratic acts (THREAT)"³. This could explain why PHAVPR, HSST, and THREAT are more prevalent during offline violent events led by right-wingers and are primarily associated with left-aligned political influencers. Moreover, determining whether violent metaphors imply actual harm is also challenging. Our results have to be interpreted in light of these limitations, and we advise future studies to exercise caution when applying the classifiers to downstream tasks involving such reverse discourse patterns and metaphors.

The indirect mentions of incivility, especially for dimensions PHAVPR, HSST, and THREAT, can also be found in the discourse of right-aligned political influencers. Even though this may not be called uncivil, indirect mentions of incivility still risk escalating into “violence for violence,” where users respond to the uncivil behavior of their outgroup in similarly uncivil ways. For instance, we find some direct uncivil expressions from the left-aligned users, such as “I want to gather everyone from the inauguration and surround Brasília to see who’s stronger (PHAVPR)”, “An end to these fascist Nazis disguised as Novo (HSST)”, “It’s time to confront the coup without mediation (THREAT)”. Such cycles can be more detrimental to democratic processes than incivility itself. However, the indirect mentions of incivility can also be beneficial as

they draw public attention to stop political violence and enable disadvantaged groups to be seen. Future research could further enhance automated techniques to distinguish between direct and indirect mentions of incivility and assess their respective impacts.

The recent global rise of right-wing populism has often been associated with increased political incivility and violence. In Brazil, this trend was reflected during the Bolsonaro administration (2018–2022). However, growing dissatisfaction with Bolsonaro’s pandemic response and perceived authoritarianism contributed to a left-leaning resurgence, culminating in Lula’s 2022 presidential victory. Lula’s campaign, driven by digital mobilization, has marked a renewed ‘pink tide’ reminiscent of the early 2000s [36]. This shift may account for the prevalence of both direct and indirect uncivil discourse among left-leaning users.

Additionally, the observed mixed information flow pattern suggests a strong tendency toward echo chamber formation on social media. Ordinary users who follow a political influencer are also more likely to follow another influencer who retweets that influencer. This dynamic is particularly pronounced among politicians, individual influencers, and their shared followers. Such patterns may be driven by platform algorithms and the increasing presence of individual supporters acting as political influencers.

Like many previous studies, this study is not without limitations. For instance, the automatic classification models, while useful, are less accurate than human labeling—a limitation shared by other widely used uncivil detection models like Perspective API [28]. Additionally, we only collect data from political influencers associated with 204 survey users, a rather small sample. However, the sample’s attribute distributions do not differ significantly from the overall survey population, which is representatively sampled from Brazil’s population, especially the Twitter/X political information seekers. Our analysis, therefore, reports how a representative sample experiences uncivil content online. Furthermore, this study focuses on one platform, while right-wing users may be more active on other platforms such as Gab and Telegram. Despite these limitations, this study provides valuable insights into the dynamics of incivility in Brazilian politics and suggests the potential issues of using automatic classifiers detecting incivility.

Theoretically, the multidimensional conceptual framework of incivility is applicable across time periods, political cultural contexts, and platforms. More general dimensions such as IMP and HSST can also be applied beyond the political domain. However, we strongly recommend testing and retraining the classifiers when applying them to other settings, as the training samples were primarily drawn from the 2022 Brazilian Presidential Election. Additionally, other methodologies employed in this study—such as non-parametric modeling, identity annotation, and network analysis—can be also applied to other datasets containing time stamps, user profiles, and interaction data.

The leakage of data in this work might pose a risk to certain individuals. Thus, all datasets are securely stored to ensure confidentiality, and data sharing is not feasible. The Python and R scripts used to generate the main plots are available on the Harvard Dataverse: <https://doi.org/10.7910/DVN/M552GM>. The classifiers used to predict multidimensional incivility are available in the following GitHub repository: https://github.com/yuanzhang1227/Multidimensional_Political_Incivility_Detection.

A Appendix

A.1 Survey Sample validation

Figure 8: Comparison of distributions on Age, Gender, Ethnic, Religion, Income, and Education between survey respondents (N = 1,018) and its sub-sample (N = 204).

Figure 9: Distribution of ideological position among the survey sub-sample (N = 204).

A.2 Identification of Political Influencers

We use a heuristic strategy of identifying political influencers from the 57,645 accounts followed by survey respondents. We define political influencers as a composition of both ordinary citizens and celebrities (e.g., politicians, parties, media outlets, journalists, and individuals) who satisfy two conditions: 1) are influential and 2) are likely to produce political content. According to this definition, we select political influencers in three steps. Firstly, we identify influential accounts that have a number of followers exceeding 1,000. Fig. 10 displays the Complementary Cumulative Distribution Function (CCDF) plot for the number of followers of accounts followed by survey respondents. We establish a threshold of 1,000 followers, and only accounts exceeding this threshold are retained, accounting for 63% of the total accounts who are followed by survey respondents.

Figure 10: The complementary cumulative distribution function (CCDF) plot of the number of followers of Twitter/X accounts followed by survey respondents, with cutoffs at 1,000.

Second, from the accounts with more than 1,000 followers, we further select Brazilian accounts based on the location information displayed in their profile (Brazil or Brazilian cities). Third, we filter the accounts that might produce political information from the Brazilian influencers, covering categories of politicians, parties, media outlets, journalists, and individuals. We manually examine approximately 2,000 random profile examples and create a politically relevant keyword list based on these samples. Accounts potentially generating political content are identified by matching politics-related keywords in their profiles and supplemented by additional lists of politicians (based on 2022 presidential election candidates), parties, and media outlets (based on Digital News Report 2022 produced by Reuters Institute Oxford). See Tab. 8 for more details.

The three steps result in identifying 2,307 Brazilian political influencers from the 57,645 followed accounts.

Codebook for Socio-Political Identity Annotation

This codebook is designed to guide the systematic annotation of socio-political attributes of Brazilian Twitter/X political influencers, with a focus on account type, ideological position, campaign support, and social identity. It provides detailed instructions for coding five key dimensions: (1) whether the user potentially produces political content, (2) the type of account (e.g., politician, media, individual), (3) the user's ideological position, if declared, (4) explicit support for political candidates in the 2022 Brazilian Presidential Election (Lula or Bolsonaro), and (5) any self-disclosed or publicly visible social identities (e.g., women, Black, LGBTQ, religious). These annotations support the analysis of uncivil political discourse on Brazilian Twitter/X.

Table 8: Identification of Political Influencers

Criteria	Category	Keywords
Political Keywords	General	política, político, political, politics, democracia, democracy
	Election	bolsonaro, bolsonarista, lula, lulista, candidato, partido, presidente
	Public sector	federal, conselho nacional de, ministro, senador, deputado, governador, prefeito, vereador, secretário
	Ideology	conservador, conservative, liberal, liberalismo, libertairia, esquerdopata, esquerda, direita, direitista, comunista, comunismo, nacionalista, patriota, globalista, feminista, armamentista, fascista, racist, colonialista, socialista, ativista, progressista
	Topic (culture)	aborto, mulher, preta, lgbt, gay, bissexualismo, homophobic, católico, jesus, deus, ambiente, clima, justiça, imigrante, foreigner
	Topic (economic)	economia, bem-estar, pobre, desigualdade
Political Accounts	Political party	Partido da Mulher Brasileira, Partido dos Trabalhadores, Partido da Social Democracia Brasileira, Progressistas, Partido Democrático Trabalhista, Partido Trabalhista Brasileiro, União Brasil, Partido Liberal, Partido Socialista Brasileiro, Republicanos, Cidadania, Partido Comunista do Brasil, Partido Social Cristão, Podemos, Partido Social Democrático, Partido Verde, Patriota, Solidariedade, Partido da Mobilização Nacional, Avante, Partido Trabalhista Cristão, Partido Socialismo e Liberdade, Democracia Cristã, Partido Renovador, Trabalhista Brasileiro, Partido Republicano da Ordem Social, Partido da Mulher Brasileira, Partido Novo, Rede Sustentabilidade, Partido Socialista dos Trabalhadores Unificado, Partido Comunista Brasileiro, Partido da Causa Operária, Unidade Popular, Avante, Agir, MDB Nacional
	Politician	Aldo Rebelo, Soraya Thronicke, Jair Bolsonaro, Luiz Inácio Lula da Silva, Ciro Gomes, Simone Tebet, André Janones, Luiz Felipe D’Avila, José Maria Eymael, Leonardo Péricles, Sofia Manzano, Vera Lúcia Salgado, Luciano Bivar, Pablo Marçal, Wilson Witzel, Janaina Paschoal, José Reguff, Ibaneis Rocha, Renan Filho, Renato Casagrande, Michel Temer, Jorge Kajuru, Padre Kelmon
Media Keywords	Individual aggregator	jornalista, journalist, correspondent, repórter, comandante, commentator, comentarista, influencer, news, semanal
Media Accounts	News outlet	Globo News online (incl. G1), UOL online, Record News online (incl. R7.com), O Globo online, Band News online, Folha de S. Paulo online, O Estado de S. Paulo online, BBC News online, Rede TV News online, notícias, Jornal Extra online, TV SBT (incl. SBT Brasil), TV Band News, CNN, TV Brasil (public broadcaster)

COL 1: Politics

Options: Yes / No

Criteria:

Code **Yes** if any of the following conditions are met:

1. The text is posted by a Brazilian politician, political party, other political agencies, media outlets, or media workers such as journalists/reporters/commenters/columnists (note: media outlets or media workers for sports/music/fashion or other non-political industries do not count).
2. The text include any words related to ideological position leaning (e.g., left, right, liberal, conservative etc.), campaign or social movements slogans (e.g., "VoltaLula," "ForaBolsonaro," "Eleicoes2022"), or mentions political/social issues (e.g., "social welfare", "environmental policy", "abortion rights", "minority rights").

Otherwise, code **No**.

If the Politics column is marked 'Yes', assign the following labels accordingly:

COL 2: Account Type

Options: Politician / Media / Individual

Criteria:

- Code **Politician** if the user is a Brazilian politician.
- Code **Media** if the user is a media outlet or a media worker such as journalist/reporter/commenter/-columnist.
- Code **Individual** if the user is an ordinary user, including celebrities, scholars, and activists.

COL 3: Ideological Position

Options: Left / Right / Center

Criteria:

- **For Politicians**, assign ideology based on party affiliation:
 - **Left** for PT, PSOL, PCdoB, PDT, PSB, and other left-wing parties
 - **Right** for PL, NOVO, and other right-wing parties
 - **Center** for centrist parties (e.g., MDB, PSD)
- **For Media**, refer to known political orientation based on public evaluations (e.g., Media Bias/Fact Check). Leave blank if unclear.
- **For Individuals**, code based on explicit ideological declaration in the profile:
 - **Left**: mentions being left, liberal, or supports left-wing agendas
 - **Right**: mentions being right, conservative, or supports right-wing agendas
 - **Center**: declares that they are at central position (e.g., neither left nor right)
 - Leave blank if no ideological position is stated explicitly.

COL 4: Campaign Support

Options: Lula camp / Bolsonaro camp

Criteria:

- Code **Lula camp** if the user is a politician and endorsed Lula during the 2022 Brazilian Presidential Election, or an Individual indicating support Lula or against Bolsonaro (e.g., ForaBolsonaro).
- Code **Bolsonaro camp** if the user is a politician and endorsed Bolsonaro during the 2022 Brazilian Presidential Election, or an Individual indicating support Bolsonaro or against Lula (e.g., LulaLadrão).
- If neither support nor opposition is clearly indicated, leave blank.

COL 5: Social Identity

Options: Women / Black / LGBTQ / Religious

Criteria:

- Code **Women** if the user represents image for the women group (e.g., advocate for women; other female titles such as mom, girl, grandma do not count) or supports feminism.
- Code **Black** if the user self-identifies as Black or advocates for Black rights.
- Code **LGBTQ** if the user self-identifies as LGBTQ (e.g., gay, lesbian, trans, bi) or supports LGBTQ rights.
- Code **Religious** if the user expresses religious affiliation (e.g., Christian, Evangelical, Catholic) or references faith-based communities, ministries, or biblical quotes.
- Use multiple labels if applicable, e.g., (Women, Black).
- If no identity is clearly indicated, leave blank.

Please note that not all political influencers disclose their identities, we assign those unrevealed profiles as “Unlabeled”.

A.3 Codebook for Multidimensional Incivility Annotation

The training samples for the automatic classifier are drawn from a corpus compiled by the Swiss National Science Foundation (SNSF) project *From Uncivil Disagreement to Political Unrest? A Cross-Platform & Cross-National Analysis of the Offline Consequences of Online Incivility*. The dataset includes posts from media outlets, political candidates, and political parties across multiple platforms—Twitter/X, Facebook, YouTube, Telegram, etc.—with a detailed source list provided in Tab. 9. Media outlets are selected based on the most popular sources provided in the Digital News Report 2022, while political candidates and parties include those who participated in the 2022 Brazilian Presidential Election. Comments on these posts are also collected.

Training samples, including both uncivil (positive) and civil (negative) examples, are selected using the Perspective API in combination with stratified random sampling—stratified by platform and user account—for manual annotation by human coders.

The following codebook guides the annotation process across four dimensions: Impoliteness, Physical Harm and Violent Political Rhetoric, Hate Speech and Stereotyping, and Threats to Democratic Institutions and Values. This codebook is also part of the project. It defines political incivility across multiple dimensions and provides examples to guide coders in annotation.

DIM 1: Impoliteness

Definition: Here we code any kind of rudeness and disrespect, which can be directed by means of offensive language against any kind of person or group. This is meant to be understood as impoliteness in general, it does not have to be politically motivated. By impoliteness and disrespect, we understand more specifically:

- Name-calling (e.g., “weirdo,” “traitor,” “crackpot,” “thieves”)
- Aspersions (e.g., “reckless,” “stupid,” “irrational,” “un-American”)
- Synonyms for lying (e.g., “hoax,” “farce”)
- Hyperbole (e.g., “outrageous,” “heinous”)
- Words that indicate non-cooperation (e.g., “polarized,” “filibuster,” “inflexible”)
- Pejorative speak (e.g., “bellyache,” “doublespeak,” “gibberish”)
- Vulgarity (e.g., “damn,” “shit,” “hell,” “assholes”)
- Belittling others
- Using all-caps or excessive exclamation marks to imitate shouting or screaming (e.g., “a MILLION social parasites,” “Send them back!!!”) (context dependent)

Operationalization:

1 = Present: Message contains impoliteness.

0 = Not Present: No impoliteness.

Table 9: List of Sources for Traing Data

Account	Type	Account	Type
<i>Media Outlets</i>			
Globo News online (incl. G1)	Media Outlet	UOL online	Media Outlet
Record News online (incl. R7.com)	Media Outlet	O Globo online	Media Outlet
Band News online	Media Outlet	Folha de S. Paulo online	Media Outlet

Rede Sustentabilidade	Political Party	Partido Socialista dos Trabalhadores Unificado	Political Party
Partido Comunista Brasileiro	Political Party	Partido da Causa Operária	Political Party
Unidade Popular	Political Party	Agir	Political Party
MDB Nacional	Political Party		

DIM 2: Physical Harm and Violent Political Rhetoric

Definition:

- Messages threatening physical harm against political actors or inciting others to inflict harm. Includes direct expressions of intent to cause physical harm or indirect expressions (metaphorically speaking). The rule of thumb of classifying this dimension is to check whether there is an intention of causing actual physical harm, and it should be combined with specific contexts.
- Advocating for violence as a means to achieve political ends, or suggesting that violent acts against certain individuals or groups are justified.

Examples:

- “I will kill you” (direct violence). Or: “hang @MikePence!”
- ”The only way to get things done is to take it to the streets and make them listen, by force if necessary.”

PLEASE NOTE:

- Do not code this category if the underlying meaning does not describe violence (for instance in ‘get his ass kicked’ or ‘burn in hell’ – these are ‘impolite’ expressions of anger) or if the phrase is meant ironically or sarcastically (‘why don’t you shoot them all if you believe violence solves any problems’), or if someone’s violent rhetoric is just quoted. Only code if there is a clear intention of violence.

Operationalization:

1 = Present: Contains physical harm or violent political rhetoric.

0 = Not Present: No physical harm or violent political rhetoric.

DIM 3: Hate Speech and Stereotyping

Definition: Messages including discriminatory statements against individuals and groups who are attributed negative stereotypes based on gender identity, sexual orientation, religious beliefs, race, nationality, ideology, or disability. Messages often include plural forms and imply references to groups based on social identity.

- Messages that are misogynist, xenophobic, sexist, racist, ...
- Depicting people negatively as members of an outgroup or pariah group.
- Targeted criticism based on an individual’s personality, appearance, or looks.
- Making over-generalizing assumptions about thoughts or behaviors of groups or individuals based on stereotypes.

Examples:

- “Muslims are terrorist sympathizers.”
- “Gun-owners/supporters are paranoid.”
- ”Liberals are less patriotic.”
- ”Immigrants rely on social benefits.”
- ”Women are poor drivers.”

PLEASE NOTE:

- Social identity-based groups include racial and ethnic communities, religious groups, LGBTQ+ communities, women, people with disabilities, or any other group defined by shared social attributes. Promoting tolerance, respect, and understanding is crucial in fostering a more inclusive and equitable society.
- Rare cases where politicians are attacked as members of these groups (as women, as blacks, etc) should also be coded here.
- Political ideology can also become relevant here. Clearly discriminatory, overgeneralizing pejoratives against people as Nazis, fascists, gun-toting conservatives, – or as communists, leftist scum, woke snowflakes would also be coded here.

- Positive or neutral stereotyping is never coded.

Operationalization:

1 = Present: Message contains at least one instance of hate speech and stereotyping.

0 = Not Present: Message does not exhibit hate speech and stereotyping.

DIM 4: Threats to Democratic Institutions and Values

Definition: Messages undermining democratic procedures and institutions, the democratic state, and democratic values.

- Messages promoting force against the government or the forceful replacement of the existing government, resorting to violence in coup or revolution.
- Promoting Autocracy. Messages that argue in favor of undemocratic forms of governance, such as autocracy or dictatorship, over democratic principles.
- Discrediting democratic institutions. Messages that aim to delegitimize or undermine the importance, role, or integrity of key democratic institutions. For instance, suggesting that elections are rigged without any substantive proof, or consistently attacking the judiciary or the media.
- Discrediting democratic values. This includes discrediting Freedom of Speech (to express ideas without censorship or fear), Equality (that everyone has same legal rights and opportunities), Rule of Law (that everyone must abide by the law, including those in power), Free and Fair Elections (to choose your representatives without undue influence or discrimination), Civil Liberties (protecting individuals from arbitrary government interference), Pluralism (acceptance of diverse viewpoints), Accountability (elected officials and institutions are answerable to the public for their actions).

Examples:

- "We don't need elections, we need a strong leader who knows what's best."
- "The entire electoral process is a sham. Our votes don't matter."

Operationalization:

1 = Present: Message contains at least one instance of threats to democratic institutions and values.

0 = Not Present: Message does not exhibit threats to democratic institutions and values.
