| <b>What is AWS Systems Manager?</b> .....  | <b>1</b>  |
| How can Systems Manager benefit my operations? .....   | 1         |
| Who should use Systems Manager? .....  | 2         |
| What are the main features of Systems Manager? .....   | 2         |
| Supported AWS Regions .....  | 2         |
| Supported operating systems and machine types .....  | 3         |
| Supported operating systems for Systems Manager .....  | 3         |
| Supported machine types in hybrid and multicloud environments .....                                  | 10        |
| <b>Setting up managed nodes for AWS Systems Manager</b> .....  | <b>12</b> |
| Managing EC2 instances with Systems Manager .....  | 12        |
| Configure instance permissions required for Systems Manager .....                                    | 13        |
| Improve the security of EC2 instances by using VPC endpoints for Systems Manager .....               | 24        |
| Managing nodes in hybrid and multicloud environments with Systems Manager .....                      | 29        |
| Create the IAM service role required for Systems Manager in hybrid and multicloud environments ..... | 31        |
| Create a hybrid activation to register nodes with Systems Manager .....                              | 39        |
| Install SSM Agent on hybrid Linux nodes .....  | 45        |
| Install SSM Agent on hybrid Windows Server nodes .....   | 51        |
| Managing edge devices with Systems Manager .....   | 56        |
| Create an IAM service role for your edge devices .....   | 58        |
| Configure your edge devices for AWS IoT Greengrass .....   | 64        |
| Update the AWS IoT Greengrass token exchange role and install SSM Agent on your edge devices .....   | 64        |
| Creating an AWS Organizations delegated administrator for Systems Manager .....                      | 64        |
| Using a delegated administrator with Change Manager .....  | 65        |
| Using a delegated administrator with Explorer .....  | 66        |
| Using a delegated administrator with OpsCenter .....   | 66        |
| Using a delegated administrator with Quick Setup .....   | 66        |
| General setup .....  | 67        |
| Sign up for an AWS account .....   | 67        |
| Create a user with administrative access .....   | 67        |
| <b>Setting up AWS Systems Manager</b> .....  | <b>69</b> |
| Setting up Systems Manager console access .....  | 69        |
| Systems Manager onboarding policy .....  | 69        |

|  |            |
|--|------------|
| AWS Systems Manager console operator policy .....                                | 75         |
| AWS Systems Manager console operator read-only policy .....                      | 79         |
| Setting up Systems Manager unified console for an organization .....             | 81         |
| Setting up Systems Manager unified console for a single account and Region ..... | 83         |
| Disabling the Systems Manager unified console .....                              | 84         |
| <b>Complete node tasks with Systems Manager .....</b>                            | <b>85</b>  |
| Perform a node task with Systems Manager .....                                   | 85         |
| Prerequisites .....  | 85         |
| Launch an instance using an AMI with SSM Agent preinstalled .....                | 85         |
| Connect to your managed instance using Systems Manager .....                     | 87         |
| Clean up your instance .....   | 87         |
| Review node insights .....   | 87         |
| Adding or removing widgets .....   | 90         |
| Rearranging widgets .....  | 90         |
| Exploring nodes .....  | 91         |
| Exploring nodes using console filters .....                                      | 92         |
| Exploring nodes using text prompts in Amazon Q .....                             | 97         |
| Viewing individual node details and taking action on a node .....                | 103        |
| Downloading or exporting a managed node report .....                             | 105        |
| Managing node report content and appearance .....                                | 109        |
| Diagnosing and remediating .....   | 110        |
| Diagnosing and remediating failed deployments .....                              | 111        |
| Diagnosing and remediating drifted configurations .....                          | 112        |
| Diagnosing and remediating unmanaged Amazon EC2 instances .....                  | 113        |
| Remediation impact types of runbook actions .....                                | 120        |
| Viewing execution history details for remediations .....                         | 122        |
| Adjusting Systems Manager settings .....   | 123        |
| Account setup settings .....   | 123        |
| Organizational setup settings .....  | 124        |
| Diagnose and remediate settings .....  | 124        |

# What is AWS Systems Manager?

AWS Systems Manager helps you centrally view, manage, and operate nodes at scale in AWS, on-premises, and multicloud environments. With the launch of an unified console experience, Systems Manager consolidates various tools to help you complete common node tasks across AWS accounts and Regions.

To use Systems Manager, nodes must be [managed](#), which means SSM Agent is installed on the machine and the agent can communicate with the Systems Manager service. To help you identify why nodes aren't reporting as *managed*, Systems Manager offers a one-click agent issue diagnosis and remediation runbook that you can configure to run automatically according to a schedule you define. This feature helps identify why nodes can't connect to Systems Manager, including networking misconfigurations. This feature also provides recommended runbooks for remediating networking issues and other problems preventing nodes from being configured as managed nodes.

The unified console experience also includes a dashboard that provides a high-level overview of your nodes. You can drill down for more specific node insights such as which nodes are running outdated operating system (OS) software. You can also use filters for granular views based on instance metadata like OSs, AWS Regions, accounts, and SSM Agent versions. These filters help you retrieve relevant information at a specific account or application level across your entire organization.

## How can Systems Manager benefit my operations?

Benefits of Systems Manager include the following:

- **Enhance visibility across your entire infrastructure**

Systems Manager provides a centralized view of nodes across your organization's accounts and Regions. Quickly access instance information such as ID, name, OS details, and installed agents. Use Amazon Q Developer to query instance metadata using natural language, helping you identify issues and take action faster.

- **Boost operational efficiency with automation**

Automate common operational tasks and reduce time and effort required to maintain your systems. Systems Manager provides safe and secure remote management of your nodes at scale without logging into your servers. You no longer need to use bastion hosts, SSH, or remote

PowerShell. Systems Manager also provides a simple way of automating common administrative tasks across groups of nodes such as registry edits, user management, and software and patch installations.

- **Simplify node management at scale in any environment**

Systems Manager helps you manage nodes across AWS, on-premises, and multicloud environments. Schedule automated diagnoses to identify SSM Agent issues and remediate them with one-click runbooks. After your nodes are configured as *managed* nodes, you can execute critical operational tasks such as applying security patches, initiating logged sessions, and running commands remotely.

## Who should use Systems Manager?

Systems Manager is used by IT operations managers and operators, DevOps engineers, security and compliance managers, and IT directors and CIOs. Broadly speaking, Systems Manager is appropriate for the following:

- Organizations that want to improve the management and security of their nodes at scale.
- Organizations that want to increase visibility and operational agility when managing their infrastructure.
- Organizations that want to increase operational efficiency at scale.

## What are the main features of Systems Manager?

Primary features of Systems Manager include the following:

- Centralized views of your nodes
- Patching nodes at scale
- Automated diagnosis and remediation of common node issues

## Supported AWS Regions

For a list of AWS Regions that support [AWS Systems Manager tools](#) released before the new Systems Manager experience, see [Systems Manager service endpoints](#) in the *Amazon Web Services General Reference*.

The new Systems Manager experience, released on November 21, 2024, is available in the following AWS Regions:

- US East (N. Virginia) Region
- US East (Ohio) Region
- US West (N. California) Region
- US West (Oregon) Region
- Canada (Central) Region
- Canada West (Calgary) Region
- South America (São Paulo) Region
- Asia Pacific (Mumbai) Region
- Asia Pacific (Tokyo) Region
- Asia Pacific (Seoul) Region
- Asia Pacific (Singapore) Region
- Asia Pacific (Sydney) Region
- Europe (Frankfurt) Region
- Europe (Stockholm) Region
- Europe (Ireland) Region
- Europe (London) Region
- Europe (Paris) Region

## Supported operating systems and machine types

Before working with Systems Manager, verify that your operating system (OS), OS version, and machine type are supported as managed nodes.

### Topics

- [Supported operating systems for Systems Manager](#)
- [Supported machine types in hybrid and multicloud environments](#)

## Supported operating systems for Systems Manager

The following sections list the OSs and OS versions supported by Systems Manager.

**Note**

If you plan to manage and configure AWS IoT Greengrass core devices by using Systems Manager, those devices must meet the requirements for AWS IoT Greengrass. For more information, see [Setting up AWS IoT Greengrass core devices](#) in the *AWS IoT Greengrass Version 2 Developer Guide*.

If you plan to manage and configure AWS IoT and non-AWS edge devices, those devices must meet the requirements listed here and be configured as on-premises managed nodes for Systems Manager. For more information, see [Managing edge devices with Systems Manager](#).

**Important**

Patch Manager, a capability of Systems Manager, might not support all the OS versions listed in this topic. For a list of OS versions supported by Patch Manager, see [Patch Manager prerequisites](#).

**Operating system types**

- [Linux](#)
- [macOS \(Amazon EC2 instances only\)](#)
- [Raspberry Pi OS \(formerly Raspbian\)](#)
- [Windows Server](#)

Select an OS platform to see the supported major and minor versions.

**Linux****AlmaLinux**

| Versions | x86 | x86_64 | ARM64 |
|----------|-----|--------|-------|
| 8.3–8.10 |     | ✓      | ✓     |
| 9.x      |     | ✓      | ✓     |

## Amazon Linux 1

| Versions        | x86 | x86_64 | ARM64 |
|-----------------|-----|--------|-------|
| 2012.03–2018.03 | ✓   | ✓      |       |

### Note

Beginning with version 2015.03, Amazon Linux 1 was released in x86\_64 versions. Amazon Linux 1 reached the end of its standard support on December 31, 2020, and reached end of life on December 31, 2023, as announced in [Update on Amazon Linux AMI end-of-life](#) on the *AWS News Blog*. AWS no longer provides Amazon Machine Images (AMIs) for this operating system. AWS Systems Manager continues to provide support, however, for existing Amazon Linux 1 instances.

## Amazon Linux 2

| Versions                   | x86 | x86_64 | ARM64 |
|----------------------------|-----|--------|-------|
| 2.0 and all later versions |     | ✓      | ✓     |

## Amazon Linux 2023

| Versions                                 | x86 | x86_64 | ARM64 |
|--|-----|--------|-------|
| 2023.0.20230315.0 and all later versions |     | ✓      | ✓     |

## Bottlerocket

| Versions                     | x86_64 | ARM64 |
|------------------------------|--------|-------|
| 1.0.0 and all later versions | ✓      | ✓     |

## CentOS

| Versions                   | x86 | x86_64 | ARM64 |
|----------------------------|-----|--------|-------|
| 6.x <sup>1</sup>           | ✓   | ✓      |       |
| 7.1 and later 7.x versions |     | ✓      | ✓     |
| 8.x                        |     | ✓      | ✓     |

<sup>1</sup> To use these versions, you must use a 3.0.x version of the SSM Agent. We recommend using the latest available 3.0.x version of the SSM Agent. Later SSM Agent versions (3.1 or later) are not supported.

## CentOS Stream

| Versions | x86 | x86_64 | ARM64 |
|----------|-----|--------|-------|
| 8        |     | ✓      | ✓     |
| 9        |     | ✓      | ✓     |

## Debian Server

| Versions      | x86 | x86_64 | ARM64 |
|---------------|-----|--------|-------|
| Jessie (8)    |     | ✓      |       |
| Stretch (9)   |     | ✓      | ✓     |
| Buster (10)   |     | ✓      | ✓     |
| Bullseye (11) |     | ✓      | ✓     |
| Bookworm (12) |     | ✓      | ✓     |

## Oracle Linux

| Versions | x86 | x86_64 | ARM64 |
|----------|-----|--------|-------|
| 7.5–7.8  |     | ✓      |       |
| 8.x      |     | ✓      |       |
| 9.x      |     | ✓      |       |

## Red Hat Enterprise Linux (RHEL)

| Versions         | x86 | x86_64 | ARM64 |
|------------------|-----|--------|-------|
| 6.x <sup>1</sup> | ✓   | ✓      |       |
| 7.0–7.5          |     | ✓      |       |
| 7.6–8.x          |     | ✓      | ✓     |
| 9.x              |     | ✓      | ✓     |

<sup>1</sup> To use these versions, you must use a 3.0.x version of the SSM Agent. We recommend using the latest available 3.0.x version of the SSM Agent. Later SSM Agent versions (3.1 or later) are not supported.

## Rocky Linux

| Versions | x86 | x86_64 | ARM64 |
|----------|-----|--------|-------|
| 8.x      |     | ✓      | ✓     |
| 9.x      |     | ✓      | ✓     |

**SUSE Linux Enterprise Server (SLES)**

| Versions                   | x86 | x86_64 | ARM64 |
|----------------------------|-----|--------|-------|
| 12 and later 12.x versions |     | ✓      |       |
| 15.x                       |     | ✓      | ✓     |

**Ubuntu Server**

| Versions                | x86 | x86_64 | ARM64 |
|-------------------------|-----|--------|-------|
| 12.04 LTS and 14.04 LTS | ✓   | ✓      |       |
| 16.04 LTS and 18.04 LTS |     | ✓      | ✓     |
| 20.04 LTS and 20.10 STR |     | ✓      | ✓     |
| 22.04 LTS               |     | ✓      | ✓     |
| 23.04, 23.10            |     | ✓      | ✓     |
| 24.04 LTS               |     | ✓      | ✓     |

**macOS (Amazon EC2 instances only)**

| Version            | x86 | x86_64 | Mac with Apple silicon |
|--------------------|-----|--------|------------------------|
| 10.14.x (Mojave)   |     | ✓      |                        |
| 10.15.x (Catalina) |     | ✓      |                        |
| 11.x (Big Sur)     |     | ✓      | ✓                      |

| Version         | x86 | x86_64 | Mac with Apple silicon |
|-----------------|-----|--------|------------------------|
| 12.x (Monterey) |     | ✓      | ✓                      |
| 13.x (Ventura)  |     | ✓      | ✓                      |
| 14.x (Sonoma)   |     | ✓      | ✓                      |
| 15.x (Sequoia)  |     | ✓      | ✓                      |

**Note**

macOS is not supported in all AWS Regions. For more information about Amazon EC2 support for macOS, see [Amazon EC2 Mac instances](#) in the *Amazon EC2 User Guide*.

## Raspberry Pi OS (formerly Raspbian)

| Version     | ARM32 |
|-------------|-------|
| 8 (Jessie)  | ✓     |
| 9 (Stretch) | ✓     |

### More info

- [Manage Raspberry Pi devices using AWS Systems Manager](#)

## Windows Server

SSM Agent requires Windows PowerShell 3.0 or later to run certain AWS Systems Manager documents (SSM documents) on Windows Server instances (for example, the legacy `AWS-ApplyPatchBaseline` document). Verify that your Windows Server instances are running Windows Management Framework 3.0 or later. This framework includes Windows PowerShell. For more information, see [Windows Management Framework 3.0](#).

| Version                       | x86 | x86_64 | ARM64 |
|-------------------------------|-----|--------|-------|
| 2008 <sup>1</sup>             | ✓   | ✓      |       |
| 2008 R2 <sup>1</sup>          |     | ✓      |       |
| 2012 and 2012 R2 <sup>2</sup> |     | ✓      |       |
| 2016                          |     | ✓      |       |
| 2019                          |     | ✓      |       |
| 2022                          |     | ✓      |       |

<sup>1</sup> **Windows Server 2008 and 2008 R2 support:** As of January 14, 2020, Windows Server 2008 is no longer supported for feature or security updates from Microsoft. Legacy Amazon Machine Images (AMIs) for Windows Server 2008 and 2008 R2 still include version 2 of SSM Agent preinstalled, but Systems Manager no longer officially supports 2008 versions and no longer updates the agent for these versions of Windows Server. In addition, SSM Agent version 3 might not be compatible with all operations on Windows Server 2008 and 2008 R2. The final officially supported version of SSM Agent for Windows Server 2008 versions is 2.3.1644.0.

<sup>2</sup> **Windows Server 2012 and 2012 R2 support:** Windows Server 2012 and 2012 R2 reached end of support on October 10, 2023. To use SSM Agent with these versions, we recommend using Extended Security Updates (ESUs) from Microsoft. For more information, see [Windows Server 2012 and 2012 R2 reaching end of support](#) on the Microsoft website.

## Supported machine types in hybrid and multicloud environments

Systems Manager supports a number of machine types as *managed nodes*. A managed node is any machine configured to work with Systems Manager.

This user guide uses the term *hybrid and multicloud* to refer to an environment that contains any combination of the following machine types:

- Amazon Elastic Compute Cloud (Amazon EC2) instances
- Servers on your own premises (on-premises servers)
- AWS IoT Greengrass core devices

- AWS IoT and non-AWS edge devices
- Virtual machines (VMs), including VMs in other cloud environments

For information about AWS support for hybrid and multicloud environments, see [AWS Solutions for Hybrid and Multicloud](#).

# Setting up managed nodes for AWS Systems Manager

Complete the tasks in this section to set up and configure roles, user accounts, permissions, and initial resources for using AWS Systems Manager tools. The tasks described in this section are typically performed by AWS account and systems administrators. After these steps are complete, users in your organization can use Systems Manager to configure, manage, and access your *managed nodes*. A managed node is any machine configured for use with Systems Manager in a [hybrid and multicloud](#) environment.

## Note

If you plan to use Amazon EC2 instances *and* your own computing resources in a [hybrid and multicloud](#) environment, follow the steps in [Managing EC2 instances with Systems Manager](#). That topic presents steps in the best order for completing Systems Manager setup for EC2 instances and non-EC2 machines.

If you already use other AWS services, you have completed some of these steps. However, other steps are specific to Systems Manager. Therefore, we recommend reviewing this entire section to ensure that you're ready to use all Systems Manager capabilities.

## Topics

- [Managing EC2 instances with Systems Manager](#)
- [Managing nodes in hybrid and multicloud environments with Systems Manager](#)
- [Managing edge devices with Systems Manager](#)
- [Creating an AWS Organizations delegated administrator for Systems Manager](#)
- [General setup for AWS Systems Manager](#)

## Managing EC2 instances with Systems Manager

Complete the tasks in this section to set up and configure roles, permissions, and initial resources for AWS Systems Manager. The tasks described in this section are typically performed by AWS account and systems administrators. After these steps are complete, users in your organization can use Systems Manager to configure, manage, and access Amazon Elastic Compute Cloud (Amazon EC2) instances.

**Note**

If you plan to use Systems Manager to manage and configure on-premises machines, follow the setup steps in [Managing nodes in hybrid and multicloud environments with Systems Manager](#). If you plan to use both Amazon EC2 instances *and* non-EC2 machines in a [hybrid and multicloud](#) environment, follow the steps here first. This section presents steps in the recommended order for configuring the roles, users, permissions, and initial resources to use in your Systems Manager operations.

If you already use other AWS services, you have completed some of these steps. However, other steps are specific to Systems Manager. Therefore, we recommend reviewing this entire section to ensure that you're ready to use all Systems Manager capabilities.

**Contents**

- [Configure instance permissions required for Systems Manager](#)
- [Improve the security of EC2 instances by using VPC endpoints for Systems Manager](#)

## Configure instance permissions required for Systems Manager

By default, AWS Systems Manager doesn't have permission to perform actions on your instances. You can provide instance permissions at the account level using an AWS Identity and Access Management (IAM) role, or at the instance level using an instance profile. If your use case allows, we recommend granting access at the account level using the Default Host Management Configuration.

**Note**

You can skip this step and allow Systems Manager to apply the required permissions to your instances for you when setting up the unified console. For more information, see [Setting up AWS Systems Manager](#).

## Recommended configuration for EC2 instance permissions

Default Host Management Configuration allows Systems Manager to manage your Amazon EC2 instances automatically. After you've turned on this setting, all instances using Instance

Metadata Service Version 2 (IMDSv2) in the AWS Region and AWS account with SSM Agent version 3.2.582.0 or later installed automatically become managed instances. Default Host Management Configuration doesn't support Instance Metadata Service Version 1. For information about transitioning to IMDSv2, see [Transition to using Instance Metadata Service Version 2](#) in the *Amazon EC2 User Guide*. For information about checking the version of the SSM Agent installed on your instance, see [Checking the SSM Agent version number](#). For information about updating the SSM Agent, see [Automatically updating SSM Agent](#). Benefits of managed instances include the following:

- Connect to your instances securely using Session Manager.
- Perform automated patch scans using Patch Manager.
- View detailed information about your instances using Systems Manager Inventory.
- Track and manage instances using Fleet Manager.
- Keep the SSM Agent up to date automatically.

Fleet Manager, Inventory, Patch Manager, and Session Manager are capabilities of AWS Systems Manager.

Default Host Management Configuration allows instance management without the use of instance profiles and ensures that Systems Manager has permissions to manage all instances in the Region and account. If the permissions provided aren't sufficient for your use case, you can also add policies to the default IAM role created by the Default Host Management Configuration. Alternatively, if you don't need permissions for all of the capabilities provided by the default IAM role, you can create your own custom role and policies. Any changes made to the IAM role you choose for Default Host Management Configuration applies to all managed Amazon EC2 instances in the Region and account. For more information about the policy used by Default Host Management Configuration, see [AWS managed policy: AmazonSSMManagedEC2InstanceDefaultPolicy](#). For more information about the Default Host Management Configuration, see [Managing EC2 instances automatically with Default Host Management Configuration](#).

### Important

Instances registered using Default Host Management Configuration store registration information locally in the `/lib/amazon/ssm` or `C:\ProgramData\Amazon` directories. Removing these directories or their files will prevent the instance from acquiring the necessary credentials to connect to Systems Manager using Default Host Management

Configuration. In these cases, you must use an instance profile to provide the required permissions to your instance, or recreate the instance.

### Note

This procedure is intended to be performed only by administrators. Implement least privilege access when allowing individuals to configure or modify the Default Host Management Configuration. You must turn on the Default Host Management Configuration in each AWS Region you wish to automatically manage your Amazon EC2 instances.

## To turn on the Default Host Management Configuration setting

You can turn on the Default Host Management Configuration from the Fleet Manager console. To successfully complete this procedure using either the AWS Management Console or your preferred command line tool, you must have permissions for the [GetServiceSetting](#), [ResetServiceSetting](#), and [UpdateServiceSetting](#) API operations. Additionally, you must have permissions for the `iam:PassRole` permission for the `AWSSystemsManagerDefaultEC2InstanceManagementRole` IAM role. The following is an example policy. Replace each *example resource placeholder* with your own information.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ssm:GetServiceSetting",
        "ssm:ResetServiceSetting",
        "ssm:UpdateServiceSetting"
      ],
      "Resource": "arn:aws:ssm:region:account-id:servicesetting/ssm/managed-instance/default-ec2-instance-management-role"
    },
    {
      "Effect": "Allow",
      "Action": [
        "iam:PassRole"
      ],
    }
  ]
}
```

```
"Resource": "arn:aws:iam::account-id:role/service-role/  
AWSSystemsManagerDefaultEC2InstanceManagementRole",  
"Condition": {  
  "StringEquals": {  
    "iam:PassedToService": [  
      "ssm.amazonaws.com"  
    ]  
  }  
}
```

Before you begin, if you have instance profiles attached to your Amazon EC2 instances, remove any permissions that allow the `ssm:UpdateInstanceInformation` operation. The SSM Agent attempts to use instance profile permissions before using the Default Host Management Configuration permissions. If you allow the `ssm:UpdateInstanceInformation` operation in your instance profiles, the instance will not use the Default Host Management Configuration permissions.

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Fleet Manager**.
3. Choose **Configure Default Host Management Configuration** under the **Account management** dropdown.
4. Turn on **Enable Default Host Management Configuration**.
5. Choose the IAM role used to enable Systems Manager capabilities for your instances. We recommend using the default role provided by Default Host Management Configuration. It contains the minimum set of permissions necessary to manage your Amazon EC2 instances using Systems Manager. If you prefer to use a custom role, the role's trust policy must allow Systems Manager as a trusted entity.
6. Choose **Configure** to complete setup.

After turning on the Default Host Management Configuration, it might take up to 30 minutes for your instances to use the credentials of the role you chose. You must turn on the Default Host Management Configuration in each Region you wish to automatically manage your Amazon EC2 instances.

## Alternative configuration for EC2 instance permissions

You can grant access at the individual instance level by using an AWS Identity and Access Management (IAM) instance profile. An instance profile is a container that passes IAM role information to an Amazon Elastic Compute Cloud (Amazon EC2) instance at launch. You can create an instance profile for Systems Manager by attaching one or more IAM policies that define the necessary permissions to a new role or to a role you already created.

### Note

You can use Quick Setup, a capability of AWS Systems Manager, to quickly configure an instance profile on all instances in your AWS account. Quick Setup also creates an IAM service role (or *assume* role), which allows Systems Manager to securely run commands on your instances on your behalf. By using Quick Setup, you can skip this step (Step 3) and Step 4. For more information, see [AWS Systems Manager Quick Setup](#).

Note the following details about creating an IAM instance profile:

- If you're configuring non-EC2 machines in a [hybrid and multicloud](#) environment for Systems Manager, you don't need to create an instance profile for them. Instead, configure your servers and VMs to use an IAM service role. For more information, see [Create the IAM service role required for Systems Manager in hybrid and multicloud environments](#).
- If you change the IAM instance profile, it might take some time for the instance credentials to refresh. SSM Agent won't process requests until this happens. To speed up the refresh process, you can restart SSM Agent or restart the instance.

Depending on whether you're creating a new role for your instance profile or adding the necessary permissions to an existing role, use one of the following procedures.

### To create an instance profile for Systems Manager managed instances (console)

1. Open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **Roles**, and then choose **Create role**.
3. For **Trusted entity type**, choose **AWS service**.
4. Immediately under **Use case**, choose **EC2**, and then choose **Next**.
5. On the **Add permissions** page, do the following:

- Use the **Search** field to locate the **AmazonSSMManagedInstanceCore** policy. Select the check box next to its name, as shown in the following illustration.

The console retains your selection even if you search for other policies.

- If you created a custom S3 bucket policy in the previous procedure, [\(Optional\) Create a custom policy for S3 bucket access](#), search for it and select the check box next to its name.
  - If you plan to join instances to an Active Directory managed by AWS Directory Service, search for **AmazonSSMDirectoryServiceAccess** and select the check box next to its name.
  - If you plan to use EventBridge or CloudWatch Logs to manage or monitor your instance, search for **CloudWatchAgentServerPolicy** and select the check box next to its name.
6. Choose **Next**.
  7. For **Role name**, enter a name for your new instance profile, such as **SSMInstanceProfile**.

#### **Note**

Make a note of the role name. You will choose this role when you create new instances that you want to manage by using Systems Manager.

8. (Optional) For **Description**, update the description for this instance profile.
9. (Optional) For **Tags**, add one or more tag-key value pairs to organize, track, or control access for this role, and then choose **Create role**. The system returns you to the **Roles** page.

### To add instance profile permissions for Systems Manager to an existing role (console)

1. Open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **Roles**, and then choose the existing role you want to associate with an instance profile for Systems Manager operations.
3. On the **Permissions** tab, choose **Add permissions, Attach policies**.
4. On the **Attach policy** page, do the following:

- Use the **Search** field to locate the **AmazonSSMManagedInstanceCore** policy. Select the check box next to its name.
  - If you have created a custom S3 bucket policy, search for it and select the check box next to its name. For information about custom S3 bucket policies for an instance profile, see [\(Optional\) Create a custom policy for S3 bucket access](#).
  - If you plan to join instances to an Active Directory managed by AWS Directory Service, search for **AmazonSSMDirectoryServiceAccess** and select the check box next to its name.
  - If you plan to use EventBridge or CloudWatch Logs to manage or monitor your instance, search for **CloudWatchAgentServerPolicy** and select the check box next to its name.
5. Choose **Attach policies**.

For information about how to update a role to include a trusted entity or further restrict access, see [Modifying a role](#) in the *IAM User Guide*.

### (Optional) Create a custom policy for S3 bucket access

Creating a custom policy for Amazon S3 access is required only if you're using a VPC endpoint or using an S3 bucket of your own in your Systems Manager operations. You can attach this policy to the default IAM role created by the Default Host Management Configuration, or an instance profile you created in the previous procedure.

For information about the AWS managed S3 buckets you provide access to in the following policy, see [SSM Agent communications with AWS managed S3 buckets](#).

1. Open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **Policies**, and then choose **Create policy**.
3. Choose the **JSON** tab, and replace the default text with the following.

```
{
  "Version": "2012-10-17",
  "Statement": [
    1
    {
      "Effect": "Allow",
      "Action": "s3:GetObject",
      "Resource": [
        "arn:aws:s3:::aws-ssm-region/*",
```

```

        "arn:aws:s3::aws-windows-downloads-region/*",
        "arn:aws:s3::amazon-ssm-region/*",
        "arn:aws:s3::amazon-ssm-packages-region/*",
        "arn:aws:s3::region-birdwatcher-prod/*",
        "arn:aws:s3::aws-ssm-distributor-file-region/*",
        "arn:aws:s3::aws-ssm-document-attachments-region/*",
        "arn:aws:s3::patch-baseline-snapshot-region/*"
    ],
    },
    2
    "Effect": "Allow",
    "Action": [
        "s3:GetObject",
        "s3:PutObject",

"s3:PutObjectAcl", 3

"s3:GetEncryptionConfiguration" 4
    ],
    "Resource": [
        "arn:aws:s3::amzn-s3-demo-bucket/*",
        "arn:aws:s3::amzn-s3-demo-
bucket" 5
    ]
    }
    ]
}

```

<sup>1</sup> The first Statement element is required only if you're using a VPC endpoint.

<sup>2</sup> The second Statement element is required only if you're using an S3 bucket that you created to use in your Systems Manager operations.

<sup>3</sup> The PutObjectAcl access control list permission is required only if you plan to support cross-account access to S3 buckets in other accounts.

<sup>4</sup> The GetEncryptionConfiguration element is required if your S3 bucket is configured to use encryption.

<sup>5</sup> If your S3 bucket is configured to use encryption, then the S3 bucket root (for example, `arn:aws:s3:::amzn-s3-demo-bucket`) must be listed in the **Resource** section. Your user, group, or role must be configured with access to the root bucket.

4. If you're using a VPC endpoint in your operations, do the following:

In the first Statement element, replace each *region* placeholder with the identifier of the AWS Region this policy will be used in. For example, use `us-east-2` for the US East (Ohio) Region. For a list of supported *region* values, see the **Region** column in [Systems Manager service endpoints](#) in the *Amazon Web Services General Reference*.

### Important

We recommend that you avoid using wildcard characters (\*) in place of specific Regions in this policy. For example, use `arn:aws:s3:::aws-ssm-us-east-2/*` and do not use `arn:aws:s3:::aws-ssm-*/*`. Using wildcards could provide access to S3 buckets that you don't intend to grant access to. If you want to use the instance profile for more than one Region, we recommend repeating the first Statement element for each Region.

-or-

If you aren't using a VPC endpoint in your operations, you can delete the first Statement element.

5. If you're using an S3 bucket of your own in your Systems Manager operations, do the following:

In the second Statement element, replace *amzn-s3-demo-bucket* with the name of an S3 bucket in your account. You will use this bucket for your Systems Manager operations. It provides permission for objects in the bucket, using `"arn:aws:s3:::my-bucket-name/*"` as the resource. For more information about providing permissions for buckets or objects in buckets, see the topic [Amazon S3 actions](#) in the *Amazon Simple Storage Service User Guide* and the AWS blog post [IAM Policies and Bucket Policies and ACLs! Oh, My! \(Controlling Access to S3 Resources\)](#).

**Note**

If you use more than one bucket, provide the ARN for each one. See the following example for permissions on buckets.

```
"Resource": [  
  "arn:aws:s3:::amzn-s3-demo-bucket1/*",  
  "arn:aws:s3:::amzn-s3-demo-bucket2/*"  
]
```

-or-

If you aren't using an S3 bucket of your own in your Systems Manager operations, you can delete the second Statement element.

6. Choose **Next: Tags**.
7. (Optional) Add tags by choosing **Add tag**, and entering the preferred tags for the policy.
8. Choose **Next: Review**.
9. For **Name**, enter a name to identify this policy, such as **SSMInstanceProfileS3Policy**.
10. Choose **Create policy**.

## Additional policy considerations for managed instances

This section describes some of the policies you can add to the default IAM role created by the Default Host Management Configuration, or your instance profiles for AWS Systems Manager. To provide permissions for communication between instances and the Systems Manager API, we recommend creating custom policies that reflect your system needs and security requirements. Depending on your operations plan, you might need permissions represented in one or more of the other policies.

### Policy: AmazonSSMDirectoryServiceAccess

Required only if you plan to join Amazon EC2 instances for Windows Server to a Microsoft AD directory.

This AWS managed policy allows SSM Agent to access AWS Directory Service on your behalf for requests to join the domain by the managed instance. For more information, see [Seamlessly join a Windows EC2 Instance](#) in the *AWS Directory Service Administration Guide*.

### Policy: **CloudWatchAgentServerPolicy**

Required only if you plan to install and run the CloudWatch agent on your instances to read metric and log data on an instance and write it to Amazon CloudWatch. These help you monitor, analyze, and quickly respond to issues or changes to your AWS resources.

Your default IAM role created by the Default Host Management Configuration or instance profile needs this policy only if you will use features such as Amazon EventBridge or Amazon CloudWatch Logs. (You can also create a more restrictive policy that, for example, limits writing access to a specific CloudWatch Logs log stream.)

#### **Note**

Using EventBridge and CloudWatch Logs features is optional. However, we recommend setting them up at the beginning of your Systems Manager configuration process if you have decided to use them. For more information, see the [Amazon EventBridge User Guide](#) and the [Amazon CloudWatch Logs User Guide](#).

To create IAM policies with permissions for additional Systems Manager capabilities, see the following resources:

- [Restricting access to Parameter Store parameters using IAM policies](#)
- [Setting up Automation](#)
- [Step 2: Verify or add instance permissions for Session Manager](#)

## Attach the Systems Manager instance profile to an instance (console)

The following procedure describes how to attach an IAM instance profile to an Amazon EC2 instance using the Amazon EC2 console.

1. Sign in to the AWS Management Console and open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, under **Instances**, choose **Instances**.
3. Navigate to and choose your EC2 instance from the list.

4. In the **Actions** menu, choose **Security, Modify IAM role**.
5. For **IAM role**, select the instance profile you created using the procedure in [Alternative configuration for EC2 instance permissions](#).
6. Choose **Update IAM role**.

For more information about attaching IAM roles to instances, choose one of the following, depending on your selected operating system type:

- [Attach an IAM role to an instance](#) in the *Amazon EC2 User Guide*
- [Attach an IAM role to an instance](#) in the *Amazon EC2 User Guide*

Continue to [Improve the security of EC2 instances by using VPC endpoints for Systems Manager](#).

## Improve the security of EC2 instances by using VPC endpoints for Systems Manager

You can improve the security posture of your managed nodes (including non-EC2 machines in a [hybrid and multicloud](#) environment) by configuring AWS Systems Manager to use an interface VPC endpoint in Amazon Virtual Private Cloud (Amazon VPC). By using an interface VPC endpoint (interface endpoint), you can connect to services powered by AWS PrivateLink. AWS PrivateLink is a technology that allows you to privately access Amazon Elastic Compute Cloud (Amazon EC2) and Systems Manager APIs by using private IP addresses.

AWS PrivateLink restricts all network traffic between your managed instances, Systems Manager, and Amazon EC2 to the Amazon network. This means that your managed instances don't have access to the Internet. If you use AWS PrivateLink, you don't need an internet gateway, a NAT device, or a virtual private gateway.

You aren't required to configure AWS PrivateLink, but it's recommended. For more information about AWS PrivateLink and VPC endpoints, see [AWS PrivateLink and VPC endpoints](#).

### Note

The alternative to using a VPC endpoint is to allow outbound internet access on your managed instances. In this case, the managed instances must also allow HTTPS (port 443) outbound traffic to the following endpoints:

- `ssm.region.amazonaws.com`

- `ssmmessages.region.amazonaws.com`
- `ec2messages.region.amazonaws.com`

SSM Agent initiates all connections to the Systems Manager service in the cloud. For this reason, you don't need to configure your firewall to allow inbound traffic to your instances for Systems Manager.

For more information about calls to these endpoints, see [Reference: ec2messages, ssmessages, and other API operations](#).

## About Amazon VPC

You can use Amazon Virtual Private Cloud (Amazon VPC) to define a virtual network in your own logically isolated area within the AWS Cloud, known as a *virtual private cloud (VPC)*. You can launch your AWS resources, such as instances, into your VPC. Your VPC closely resembles a traditional network that you might operate in your own data center, with the benefits of using the scalable infrastructure of AWS. You can configure your VPC; you can select its IP address range, create subnets, and configure route tables, network gateways, and security settings. You can connect instances in your VPC to the internet. You can connect your VPC to your own corporate data center, making the AWS Cloud an extension of your data center. To protect the resources in each subnet, you can use multiple layers of security, including security groups and network access control lists. For more information, see the [Amazon VPC User Guide](#).

## Topics

- [VPC endpoint restrictions and limitations](#)
- [Creating VPC endpoints for Systems Manager](#)
- [Create an interface VPC endpoint policy](#)

## VPC endpoint restrictions and limitations

Before you configure VPC endpoints for Systems Manager, be aware of the following restrictions and limitations.

### Cross-Region requests

VPC endpoints don't support cross-Region requests—ensure that you create your endpoint in the same AWS Region as your bucket. You can find the location of your bucket by using the Amazon S3

console, or by using the [get-bucket-location](#) command. Use a Region-specific Amazon S3 endpoint to access your bucket; for example, `amzn-s3-demo-bucket.s3-us-west-2.amazonaws.com`. For more information about Region-specific endpoints for Amazon S3, see [Amazon S3 endpoints](#) in the *Amazon Web Services General Reference*. If you use the AWS CLI to make requests to Amazon S3, set your default region to the same region as your bucket, or use the `--region` parameter in your requests.

## VPC peering connections

VPC interface endpoints can be accessed through both *intra-Region* and *inter-Region* VPC peering connections. For more information about VPC peering connection requests for VPC interface endpoints, see [VPC peering connections \(Quotas\)](#) in the *Amazon Virtual Private Cloud User Guide*.

VPC gateway endpoint connections can't be extended out of a VPC. Resources on the other side of a VPC peering connection in your VPC can't use the gateway endpoint to communicate with resources in the gateway endpoint service. For more information about VPC peering connection requests for VPC gateway endpoints, see [VPC endpoints \(Quotas\)](#) in the *Amazon Virtual Private Cloud User Guide*.

## Incoming connections

The security group attached to the VPC endpoint must allow incoming connections on port 443 from the private subnet of the managed instance. If incoming connections aren't allowed, then the managed instance can't connect to the SSM and EC2 endpoints.

## DNS resolution

If you use a custom DNS server, you must add a conditional forwarder for any queries to the `amazonaws.com` domain to the Amazon DNS server for your VPC.

## S3 buckets

Your VPC endpoint policy must allow access to at least the Amazon S3 buckets listed in [SSM Agent communications with AWS managed S3 buckets](#).

### Note

If you use an on-premises firewall and plan to use Patch Manager, that firewall must also allow access to the appropriate patch baseline endpoint.

## Amazon CloudWatch Logs

If you don't allow your instances to access the internet, create a VPC endpoint for CloudWatch Logs to use features that send logs to CloudWatch Logs. For more information about creating an endpoint for CloudWatch Logs, see [Creating a VPC endpoint for CloudWatch Logs](#) in the *Amazon CloudWatch Logs User Guide*.

## DNS in hybrid and multicloud environment

For information about configuring DNS to work with AWS PrivateLink endpoints in [hybrid and multicloud](#) environments, see [Private DNS for interface endpoints](#) in the *Amazon VPC User Guide*. If you want to use your own DNS, you can use Route 53 Resolver. For more information, see [Resolving DNS queries between VPCs and your network](#) in the *Amazon Route 53 Developer Guide*.

## Creating VPC endpoints for Systems Manager

Use the following information to create VPC interface endpoints for AWS Systems Manager. This topic links to procedures in the *Amazon VPC User Guide*.

### Note

*region* represents the identifier for an AWS Region supported by AWS Systems Manager, such as `us-east-2` for the US East (Ohio) Region. For a list of supported *region* values, see the **Region** column in [Systems Manager service endpoints](#) in the *Amazon Web Services General Reference*.

Follow the steps in [Create an interface endpoint](#) to create the following interface endpoints:

- **com.amazonaws.*region*.ssm** – The endpoint for the Systems Manager service.
- **com.amazonaws.*region*.ec2messages** – Systems Manager uses this endpoint to make calls from SSM Agent to the Systems Manager service. Beginning with version 3.3.40.0 of SSM Agent, Systems Manager began using the `ssmmessages : *` endpoint (Amazon Message Gateway Service) whenever available instead of the `ec2messages : *` endpoint (Amazon Message Delivery Service).
- **com.amazonaws.*region*.ec2** – If you're using Systems Manager to create VSS-enabled snapshots, you need to ensure that you have an endpoint to the EC2 service. Without the EC2 endpoint defined, a call to enumerate attached Amazon EBS volumes fails, which causes the Systems Manager command to fail.

- **com.amazonaws.region.s3** – Systems Manager uses this endpoint to update SSM Agent. Systems Manager also uses this endpoint if, optionally, you choose to retrieve scripts or other files stored in buckets or upload output logs to a bucket. If the security group associated with your instances restricts outbound traffic, you must add a rule to allow traffic to the prefix list for Amazon S3. For more information, see [Modify your security group](#) in the *AWS PrivateLink Guide*.
- **com.amazonaws.region.ssmmessages** – This endpoint is required for SSM Agent to communicate with the Systems Manager service, for Run Command, and if you're connecting to your instances through a secure data channel using Session Manager. For more information, see [AWS Systems Manager Session Manager](#) and [Reference: ec2messages, ssmmessages, and other API operations](#).
- (Optional) **com.amazonaws.region.kms** – Create this endpoint if you want to use AWS Key Management Service (AWS KMS) encryption for Session Manager or Parameter Store parameters.
- (Optional) **com.amazonaws.region.logs** – Create this endpoint if you want to use Amazon CloudWatch Logs (CloudWatch Logs) for Session Manager, Run Command, or SSM Agent logs.

For information about the AWS managed S3 buckets that SSM Agent must be able to access, see [SSM Agent communications with AWS managed S3 buckets](#). If you're using a virtual private cloud (VPC) endpoint in your Systems Manager operations, you must provide explicit permission in an EC2 instance profile for Systems Manager, or in a service role for non-EC2 managed nodes in a [hybrid and multicloud](#) environment.

## Create an interface VPC endpoint policy

You can create policies for VPC interface endpoints for AWS Systems Manager in which you can specify:

- The principal that can perform actions
- The actions that can be performed
- The resources that can have actions performed on them

For more information, see [Control access to services with VPC endpoints](#) in the *Amazon VPC User Guide*.

# Managing nodes in hybrid and multicloud environments with Systems Manager

You can use AWS Systems Manager to manage both Amazon Elastic Compute Cloud (EC2) instances and a number of non-EC2 machine types. This section describes the setup tasks that account and system administrators perform to manage non-EC2 machines using Systems Manager in a [hybrid and multicloud environment](#). After these steps are complete, users who have been granted permissions by the AWS account administrator can use Systems Manager to configure and manage their organization's non-EC2 machines.

Any machine that has been configured for use with Systems Manager is called a *managed node*.

## Note

- You can register edge devices as managed nodes using the same hybrid-activation steps used for other non-EC2 machines. These types of edge devices include both AWS IoT devices and devices other than AWS IoT devices. Use the process described in this section to set up these types of edge devices.

Systems Manager also supports edge devices that use AWS IoT Greengrass Core software. The setup process and requirements for AWS IoT Greengrass core devices are different from those for AWS IoT and edge devices other than AWS edge devices. For information about registering AWS IoT Greengrass devices for use with Systems Manager, see [Managing edge devices with Systems Manager](#).

- Non-EC2 macOS machines aren't supported for Systems Manager hybrid and multicloud environments.

If you plan to use Systems Manager to manage Amazon Elastic Compute Cloud (Amazon EC2) instances, or to use both Amazon EC2 instances and non-EC2 machines in hybrid and multicloud environment, follow the steps in [Managing EC2 instances with Systems Manager](#) first.

After configuring your hybrid and multicloud environment for Systems Manager, you can do the following:

- Create a consistent and secure way to remotely manage your hybrid and multicloud workloads from one location using the same tools or scripts.

- Centralize access control for actions that can be performed on your machines by using AWS Identity and Access Management (IAM).
- Centralize auditing of the operations performed on your machines by viewing the API activity recorded in AWS CloudTrail.

For information about using CloudTrail to monitor Systems Manager actions, see [Logging AWS Systems Manager API calls with AWS CloudTrail](#).

- Centralize monitoring by configuring Amazon EventBridge and Amazon Simple Notification Service (Amazon SNS) to send notifications about service execution success.

For information about using EventBridge to monitor Systems Manager events, see [Monitoring Systems Manager events with Amazon EventBridge](#).

## About managed nodes

After you finish configuring your non-EC2 machines for Systems Manager as described in this section, your hybrid-activated machines are listed in the AWS Management Console and described as *managed nodes*. In the console, the IDs of your hybrid-activated managed nodes are distinguished from Amazon EC2 instances with the prefix "mi-". Amazon EC2 instance IDs use the prefix "i-".

A managed node is any machine configured for Systems Manager. Previously, managed nodes were all referred to as managed instances. The term *instance* now refers to EC2 instances only. The [deregister-managed-instance](#) command was named before this terminology change.

For more information, see [Working with managed nodes](#).

## About instance tiers

Systems Manager offers a standard-instances tier and an advanced-instances tier for non-EC2 managed nodes in your hybrid and multicloud environment. The standard-instances tier allows you to register a maximum of 1,000 hybrid-activated machines per AWS account per AWS Region. If you need to register more than 1,000 non-EC2 machines in a single account and Region, then use the advanced-instances tier. Advanced instances also allow you to connect to your non-EC2 machines by using AWS Systems Manager Session Manager. Session Manager provides interactive shell access to your managed nodes.

For more information, see [Configuring instance tiers](#).

## Topics

- [Create the IAM service role required for Systems Manager in hybrid and multicloud environments](#)
- [Create a hybrid activation to register nodes with Systems Manager](#)
- [Install SSM Agent on hybrid Linux nodes](#)
- [Install SSM Agent on hybrid Windows Server nodes](#)

## Create the IAM service role required for Systems Manager in hybrid and multicloud environments

Non-EC2 (Amazon Elastic Compute Cloud) machines in a [hybrid and multicloud](#) environment require an AWS Identity and Access Management (IAM) service role to communicate with the AWS Systems Manager service. The role grants AWS Security Token Service (AWS STS) [AssumeRole](#) trust to the Systems Manager service. You only need to create a service role for a hybrid and multicloud environment once for each AWS account. However, you might choose to create multiple service roles for different hybrid activations if machines in your hybrid and multicloud environment require different permissions.

The following procedures describe how to create the required service role using the Systems Manager console or your preferred command line tool.

### Using the AWS Management Console to create an IAM service role for Systems Manager hybrid activations

Use the following procedure to create a service role for hybrid activation. This procedure uses the `AmazonSSMManagedInstanceCore` policy for Systems Manager core functionality. Depending on your use case, you might need to add additional policies to your service role for your on-premises machines to be able to access other capabilities or AWS services. For example, without access to the required AWS managed Amazon Simple Storage Service (Amazon S3) buckets, Patch Manager patching operations fail.

#### To create a service role (console)

1. Open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **Roles**, and then choose **Create role**.
3. For **Select trusted entity**, make the following choices:
  1. For **Trusted entity type**, choose **AWS service**.
  2. For **Use cases for other AWS services**, choose **Systems Manager**.

### 3. Choose **Systems Manager**.

The following image highlights the location of the Systems Manager option.

Service or use case

Systems Manager ▼

Choose a use case for the specified service.

Use case

- Systems Manager**  
Allows SSM to call AWS services on your behalf
- Systems Manager - Inventory and Maintenance Windows**  
Allow AWS Systems Manager to call AWS resources on your behalf.

### 4. Choose **Next**.

### 5. On the **Add permissions** page, do the following:

- Use the **Search** field to locate the **AmazonSSMManagedInstanceCore** policy. Select the check box next to its name, as shown in the following illustration.

The console retains your selection even if you search for other policies.

- The console retains your selection even if you search for other policies.
- If you created a custom S3 bucket policy in the procedure [\(Optional\) Create a custom policy for S3 bucket access](#), search for it and select the check box next to its name.
- If you plan to join non-EC2 machines to an Active Directory managed by AWS Directory Service, search for **AmazonSSMDirectoryServiceAccess** and select the check box next to its name.
- If you plan to use EventBridge or CloudWatch Logs to manage or monitor your managed node, search for **CloudWatchAgentServerPolicy** and select the check box next to its name.

### 6. Choose **Next**.

### 7. For **Role name**, enter a name for your new IAM server role, such as **SSMServerRole**.

**Note**

Make a note of the role name. You will choose this role when you register new machines that you want to manage by using Systems Manager.

8. (Optional) For **Description**, update the description for this IAM server role.
9. (Optional) For **Tags**, add one or more tag-key value pairs to organize, track, or control access for this role.
10. Choose **Create role**. The system returns you to the **Roles** page.

## Using the AWS CLI to create an IAM service role for Systems Manager hybrid activations

Use the following procedure to create a service role for hybrid activation. This procedure uses the AmazonSSMManagedInstanceCore policy Systems Manager core functionality. Depending on your use case, you might need to add additional policies to your service role for your non-EC2 machines in a [hybrid and multicloud](#) environment to be able to access other capabilities or AWS services.

### S3 bucket policy requirement

If either of the following cases are true, you must create a custom IAM permission policy for Amazon Simple Storage Service (Amazon S3) buckets before completing this procedure:

- **Case 1** – You're using a VPC endpoint to privately connect your VPC to supported AWS services and VPC endpoint services powered by AWS PrivateLink.
- **Case 2** – You plan to use an Amazon S3 bucket that you create as part of your Systems Manager operations, such as for storing output for Run Command commands or Session Manager sessions to an S3 bucket. Before proceeding, follow the steps in [Create a custom S3 bucket policy for an instance profile](#). The information about S3 bucket policies in that topic also applies to your service role.

## AWS CLI

### To create an IAM service role for a hybrid and multicloud environment (AWS CLI)

1. Install and configure the AWS Command Line Interface (AWS CLI), if you haven't already.

For information, see [Installing or updating the latest version of the AWS CLI](#).

2. On your local machine, create a text file with a name such as `SSMSservice-Trust.json` with the following trust policy. Make sure to save the file with the `.json` file extension. Be sure to specify your AWS account and the AWS Region in the ARN where you created your hybrid activation.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "",
      "Effect": "Allow",
      "Principal": {
        "Service": "ssm.amazonaws.com"
      },
      "Action": "sts:AssumeRole",
      "Condition": {
        "StringEquals": {
          "aws:SourceAccount": "123456789012"
        },
        "ArnEquals": {
          "aws:SourceArn": "arn:aws:ssm:us-east-2:123456789012:*"
        }
      }
    }
  ]
}
```

3. Open the AWS CLI, and in the directory where you created the JSON file, run the [create-role](#) command to create the service role. This example creates a role named `SSMSserviceRole`. You can choose another name if you prefer.

### Linux & macOS

```
aws iam create-role \
  --role-name SSMSserviceRole \
  --assume-role-policy-document file://SSMSservice-Trust.json
```

## Windows

```
aws iam create-role ^
  --role-name SSMSERVICE_ROLE ^
  --assume-role-policy-document file://SSMSERVICE_ROLE_TRUST_POLICY.json
```

4. Run the [attach-role-policy](#) command as follows to allow the service role you just created to create a session token. The session token gives your managed node permission to run commands using Systems Manager.

### Note

The policies you add for a service profile for managed nodes in a hybrid and multicloud environment are the same policies used to create an instance profile for Amazon Elastic Compute Cloud (Amazon EC2) instances. For more information about the AWS policies used in the following commands, see [Configure instance permissions required for Systems Manager](#).

(Required) Run the following command to allow a managed node to use AWS Systems Manager service core functionality.

## Linux & macOS

```
aws iam attach-role-policy \
  --role-name SSMSERVICE_ROLE \
  --policy-arn arn:aws:iam::aws:policy/AmazonSSMManagedInstanceCore
```

## Windows

```
aws iam attach-role-policy ^
  --role-name SSMSERVICE_ROLE ^
  --policy-arn arn:aws:iam::aws:policy/AmazonSSMManagedInstanceCore
```

If you created a custom S3 bucket policy for your service role, run the following command to allow AWS Systems Manager Agent (SSM Agent) to access the buckets you specified in the policy. Replace *account-id* and *amzn-s3-demo-bucket* with your AWS account ID and your bucket name.

## Linux & macOS

```
aws iam attach-role-policy \  
  --role-name SSMSERVICE_ROLE \  
  --policy-arn arn:aws:iam::account-id:policy/amzn-s3-demo-bucket
```

## Windows

```
aws iam attach-role-policy ^  
  --role-name SSMSERVICE_ROLE ^  
  --policy-arn arn:aws:iam::account-id:policy/amzn-s3-demo-bucket
```

(Optional) Run the following command to allow SSM Agent to access AWS Directory Service on your behalf for requests to join the domain by the managed node. Your service role needs this policy only if you join your nodes to a Microsoft AD directory.

## Linux & macOS

```
aws iam attach-role-policy \  
  --role-name SSMSERVICE_ROLE \  
  --policy-arn arn:aws:iam::aws:policy/AmazonSSMDirectoryServiceAccess
```

## Windows

```
aws iam attach-role-policy ^  
  --role-name SSMSERVICE_ROLE ^  
  --policy-arn arn:aws:iam::aws:policy/AmazonSSMDirectoryServiceAccess
```

(Optional) Run the following command to allow the CloudWatch agent to run on your managed nodes. This command makes it possible to read information on a node and write it to CloudWatch. Your service profile needs this policy only if you will use services such as Amazon EventBridge or Amazon CloudWatch Logs.

```
aws iam attach-role-policy \  
  --role-name SSMSERVICE_ROLE \  
  --policy-arn arn:aws:iam::aws:policy/CloudWatchAgentServerPolicy
```

## Tools for PowerShell

### To create an IAM service role for a hybrid and multicloud environment (AWS Tools for Windows PowerShell)

1. Install and configure the AWS Tools for PowerShell (Tools for Windows PowerShell), if you haven't already.

For information, see [Installing the AWS Tools for PowerShell](#).

2. On your local machine, create a text file with a name such as `SSMService-Trust.json` with the following trust policy. Make sure to save the file with the `.json` file extension. Be sure to specify your AWS account and the AWS Region in the ARN where you created your hybrid activation.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "",
      "Effect": "Allow",
      "Principal": {
        "Service": "ssm.amazonaws.com"
      },
      "Action": "sts:AssumeRole",
      "Condition": {
        "StringEquals": {
          "aws:SourceAccount": "123456789012"
        },
        "ArnEquals": {
          "aws:SourceArn": "arn:aws:ssm:region:123456789012:*"
        }
      }
    }
  ]
}
```

3. Open PowerShell in administrative mode, and in the directory where you created the JSON file, run [New-IAMRole](#) as follows to create a service role. This example creates a role named `SSMServiceRole`. You can choose another name if you prefer.

```
New-IAMRole `
```

```
-RoleName SSMSERVICE_ROLE `
-AssumeRolePolicyDocument (Get-Content -raw SSMSERVICE_ROLE-Trust.json)
```

4. Use [Register-IAMRolePolicy](#) as follows to allow the service role you created to create a session token. The session token gives your managed node permission to run commands using Systems Manager.

**Note**

The policies you add for a service profile for managed nodes in a hybrid and multicloud environment are the same policies used to create an instance profile for EC2 instances. For more information about the AWS policies used in the following commands, see [Configure instance permissions required for Systems Manager](#).

(Required) Run the following command to allow a managed node to use AWS Systems Manager service core functionality.

```
Register-IAMRolePolicy `
  -RoleName SSMSERVICE_ROLE `
  -PolicyArn arn:aws:iam::aws:policy/AmazonSSMManagedInstanceCore
```

If you created a custom S3 bucket policy for your service role, run the following command to allow SSM Agent to access the buckets you specified in the policy. Replace *account-id* and *my-bucket-policy-name* with your AWS account ID and your bucket name.

```
Register-IAMRolePolicy `
  -RoleName SSMSERVICE_ROLE `
  -PolicyArn arn:aws:iam::account-id:policy/my-bucket-policy-name
```

(Optional) Run the following command to allow SSM Agent to access AWS Directory Service on your behalf for requests to join the domain by the managed node. Your server role needs this policy only if you join your nodes to a Microsoft AD directory.

```
Register-IAMRolePolicy `
  -RoleName SSMSERVICE_ROLE `
  -PolicyArn arn:aws:iam::aws:policy/AmazonSSMDirectoryServiceAccess
```

(Optional) Run the following command to allow the CloudWatch agent to run on your managed nodes. This command makes it possible to read information on a node and write it to CloudWatch. Your service profile needs this policy only if you will use services such as Amazon EventBridge or Amazon CloudWatch Logs.

```
Register-IAMRolePolicy `
  -RoleName SSMSERVICE_ROLE `
  -PolicyArn arn:aws:iam::aws:policy/CloudWatchAgentServerPolicy
```

Continue to [Create a hybrid activation to register nodes with Systems Manager](#).

## Create a hybrid activation to register nodes with Systems Manager

To set up machines other than Amazon Elastic Compute Cloud (EC2) instances as managed nodes for a [hybrid and multicloud](#) environment, you create and apply a *hybrid activation*. After you successfully complete the activation, you *immediately* receive an Activation Code and Activation ID at the top of the console page. You specify this Code and ID combination when you install AWS Systems Manager SSM Agent on non-EC2 machines for your hybrid and multicloud environment. The Code and ID provide secure access to the Systems Manager service from your managed nodes.

### Important

Systems Manager immediately returns the Activation Code and ID to the console or the command window, depending on how you created the activation. Copy this information and store it in a safe place. If you navigate away from the console or close the command window, you might lose this information. If you lose it, you must create a new activation.

### About activation expirations

An *activation expiration* is a window of time when you can register on-premises machines with Systems Manager. An expired activation has no impact on your servers or VMs that you previously registered with Systems Manager. If an activation expires then you can't register more servers or VMs with Systems Manager by using that specific activation. You simply need to create a new one.

Every on-premises server and VM you previously registered remains registered as a Systems Manager managed node until you explicitly deregister it. You can deregister a managed node on

the **Managed nodes** tab in Fleet Manager in the Systems Manager console by using the AWS CLI command [deregister-managed-instance](#), or by using the API call [DeregisterManagedInstance](#).

## About managed nodes

A managed node is any machine configured for AWS Systems Manager. AWS Systems Manager supports Amazon Elastic Compute Cloud (Amazon EC2) instances, edge devices, and on-premises servers or VMs, including VMs in other cloud environments. Previously, managed nodes were all referred to as managed instances. The term *instance* now refers to EC2 instances only. The [deregister-managed-instance](#) command was named before this terminology change.

## About activation tags

If you create an activation by using either the AWS Command Line Interface (AWS CLI) or AWS Tools for Windows PowerShell, you can specify tags. Tags are optional metadata that you assign to a resource. Tags allow you to categorize a resource in different ways, such as by purpose, owner, or environment. Here is an AWS CLI sample command to run on a local Linux machine that includes optional tags.

```
aws ssm create-activation \  
  --default-instance-name MyWebServers \  
  --description "Activation for Finance department webservers" \  
  --iam-role service-role/AmazonEC2RunCommandRoleForManagedInstances \  
  --registration-limit 10 \  
  --region us-east-2 \  
  --tags "Key=Department,Value=Finance"
```

If you specify tags when you create an activation, then those tags are automatically assigned to your managed nodes when you activate them.

You can't add tags to or delete tags from an existing activation. If you don't want to automatically assign tags to your on-premises servers and VMs using an activation, then you can add tags to them later. More specifically, you can tag your on-premises servers and VMs after they connect to Systems Manager for the first time. After they connect, they're assigned a managed node ID and listed in the Systems Manager console with an ID that is prefixed with "mi-".

### Note

You can't assign tags to an activation if you create it by using the Systems Manager console. You must create it by using either the AWS CLI or Tools for Windows PowerShell.

If you no longer want to manage an on-premises server or virtual machine (VM) by using Systems Manager, you can deregister it. For information, see [Deregistering managed nodes in a hybrid and multicloud environment](#).

## Topics

- [Using the AWS Management Console to create an activation for registering managed nodes with Systems Manager](#)
- [Using the command line to create an activation for registering managed nodes with Systems Manager](#)

## Using the AWS Management Console to create an activation for registering managed nodes with Systems Manager

### To create a managed-node activation

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Hybrid Activations**.
3. Choose **Create activation**.

-or-

If you are accessing **Hybrid Activations** for the first time in the current AWS Region, choose **Create an Activation**.

4. (Optional) For **Activation description**, enter a description for this activation. We recommend entering a description if you plan to activate large numbers of servers and VMs.
5. For **Instance limit**, specify the total number of nodes that you want to register with AWS as part of this activation. The default value is 1 instance.
6. For **IAM role**, choose a service role option that allows your servers and VMs to communicate with AWS Systems Manager in the cloud:
  - **Option 1:** Choose **Use the default role created by the system** to use a role and managed policy provided by AWS.
  - **Option 2:** Choose **Select an existing custom IAM role that has the required permissions** to use the optional custom role you created earlier. This role must have a trust relationship

policy that specifies "Service": "ssm.amazonaws.com". If your IAM role doesn't specify this principle in a trust relationship policy, you receive the following error:

```
An error occurred (ValidationException) when calling the CreateActivation
operation: Not existing role:
arn:aws:iam::<accountid>:role/SSMRole
```

For more information about creating this role, see [Create the IAM service role required for Systems Manager in hybrid and multicloud environments](#).

7. For **Activation expiry date**, specify an expiration date for the activation. The expiry date must be in the future, and not more than 30 days into the future. The default value is 24 hours.

#### Note

If you want to register additional managed nodes after the expiry date, you must create a new activation. The expiry date has no impact on registered and running nodes.

8. (Optional) For **Default instance name** field, specify an identifying name value to be displayed for all managed nodes associated with this activation.
9. Choose **Create activation**. Systems Manager immediately returns the Activation Code and ID to the console.

## Using the command line to create an activation for registering managed nodes with Systems Manager

The following procedure describes how to use the AWS Command Line Interface (AWS CLI) (on Linux or Windows Server) or AWS Tools for PowerShell to create a managed node activation.

### To create an activation

1. Install and configure the AWS CLI or the AWS Tools for PowerShell, if you haven't already.

For information, see [Installing or updating the latest version of the AWS CLI](#) and [Installing the AWS Tools for PowerShell](#).

2. Run the following command to create an activation.

### Note

- In the following command, replace *region* with your own information. For a list of supported *region* values, see the **Region** column in [Systems Manager service endpoints](#) in the *Amazon Web Services General Reference*.
- The role you specify for the *iam-role* parameter must have a trust relationship policy that specifies "Service": "ssm.amazonaws.com". If your AWS Identity and Access Management (IAM) role doesn't specify this principle in a trust relationship policy, you receive the following error:

```
An error occurred (ValidationException) when calling the CreateActivation
operation: Not existing role:
arn:aws:iam::<accountid>:role/SSMRole
```

For more information about creating this role, see [Create the IAM service role required for Systems Manager in hybrid and multicloud environments](#).

- For `--expiration-date`, provide a date in timestamp format, such as "2021-07-07T00:00:00", for when the activation code expires. You can specify a date up to 30 days in advance. If you don't provide an expiration date, the activation code expires in 24 hours.

## Linux & macOS

```
aws ssm create-activation \
  --default-instance-name name \
  --iam-role iam-service-role-name \
  --registration-limit number-of-managed-instances \
  --region region \
  --expiration-date "timestamp" \
  --tags "Key=key-name-1,Value=key-value-1" "Key=key-name-2,Value=key-value-2"
```

## Windows

```
aws ssm create-activation ^
  --default-instance-name name ^
  --iam-role iam-service-role-name ^
```

```
--registration-limit number-of-managed-instances ^
--region region ^
--expiration-date "timestamp" ^
--tags "Key=key-name-1,Value=key-value-1" "Key=key-name-2,Value=key-value-2"
```

## PowerShell

```
New-SSMActivation -DefaultInstanceName name `
  -IamRole iam-service-role-name `
  -RegistrationLimit number-of-managed-instances `
  -Region region `
  -ExpirationDate "timestamp" `
  -Tag @{"Key"="key-name-1";"Value"="key-value-1"},@{"Key"="key-
name-2";"Value"="key-value-2"}
```

Here is an example.

## Linux & macOS

```
aws ssm create-activation \
  --default-instance-name MyWebServers \
  --iam-role service-role/AmazonEC2RunCommandRoleForManagedInstances \
  --registration-limit 10 \
  --region us-east-2 \
  --expiration-date "2021-07-07T00:00:00" \
  --tags "Key=Environment,Value=Production" "Key=Department,Value=Finance"
```

## Windows

```
aws ssm create-activation ^
  --default-instance-name MyWebServers ^
  --iam-role service-role/AmazonEC2RunCommandRoleForManagedInstances ^
  --registration-limit 10 ^
  --region us-east-2 ^
  --expiration-date "2021-07-07T00:00:00" ^
  --tags "Key=Environment,Value=Production" "Key=Department,Value=Finance"
```

## PowerShell

```
New-SSMActivation -DefaultInstanceName MyWebServers `
```

```
-IamRole service-role/AmazonEC2RunCommandRoleForManagedInstances `
-RegistrationLimit 10 `
-Region us-east-2 `
-ExpirationDate "2021-07-07T00:00:00" `
-Tag
@{"Key"="Environment";"Value"="Production"},@{"Key"="Department";"Value"="Finance"}
```

If the activation is created successfully, the system immediately returns an Activation Code and ID.

## Install SSM Agent on hybrid Linux nodes

This topic describes how to install AWS Systems Manager SSM Agent on non EC2 (Amazon Elastic Compute Cloud) Linux machines in a [hybrid and multicloud](#) environment. If you plan to use Windows Server machines in a hybrid and multicloud environment, see the next step, [Install SSM Agent on hybrid Windows Server nodes](#).

### Important

This procedure is for machine types other than EC2 instances for a hybrid and multicloud environment. To download and install SSM Agent on an EC2 instance for Linux, see [Manually installing and uninstalling SSM Agent on EC2 instances for Linux](#).

Before you begin, locate the Activation Code and Activation ID that were sent to you after you completed the hybrid activation earlier in [Create a hybrid activation to register nodes with Systems Manager](#). You specify the Code and ID in the following procedure.

### To install SSM Agent on non-EC2 machines in a hybrid and multicloud environment

1. Log on to a server or VM in your hybrid and multicloud environment.
2. If you use an HTTP or HTTPS proxy, you must set the `http_proxy` or `https_proxy` environment variables in the current shell session. If you aren't using a proxy, you can skip this step.

For an HTTP proxy server, enter the following commands at the command line:

```
export http_proxy=http://hostname:port
```

```
export https_proxy=http://hostname:port
```

For an HTTPS proxy server, enter the following commands at the command line:

```
export http_proxy=http://hostname:port  
export https_proxy=https://hostname:port
```

3. Copy and paste one of the following command blocks into SSH. Replace the placeholder values with the Activation Code and Activation ID generated when you create a managed-node activation, and with the identifier of the AWS Region you want to download SSM Agent from, then press Enter.

#### Note

Note the following important details:

- `sudo` isn't necessary if you're a root user.
- Download `ssm-setup-cli` from the same AWS Region as where your hybrid activation was created.
- `ssm-setup-cli` supports a `manifest-url` option that determines the source where the agent is downloaded from. Don't specify a value for this option unless required by your organization.
- When registering instances, only use the provided download link provided for `ssm-setup-cli`. `ssm-setup-cli` shouldn't be stored separately for future use.
- You can use the script provided [here](#) to validate the signature of `ssm-setup-cli`.

*region* represents the identifier for an AWS Region supported by AWS Systems Manager, such as `us-east-2` for the US East (Ohio) Region. For a list of supported *region* values, see the **Region** column in [Systems Manager service endpoints](#) in the *Amazon Web Services General Reference*.

Additionally, `ssm-setup-cli` includes the following options:

- `version` - Valid values are `latest` and `stable`.
- `downgrade` - Allows the SSM Agent to be downgraded to an earlier version. Specify `true` to install an earlier version of the agent.

- `skip-signature-validation` - Skips the signature validation during the download and installation of the agent.

## RHEL 6.x, and CentOS 6.x

```
mkdir /tmp/ssm
curl https://s3.amazonaws.com/ec2-downloads-windows/SSMAgent/3.0.1479.0/linux_amd64/
amazon-ssm-agent.rpm -o /tmp/ssm/amazon-ssm-agent.rpm
sudo yum install -y /tmp/ssm/amazon-ssm-agent.rpm
sudo stop amazon-ssm-agent
sudo -E amazon-ssm-agent -register -code "activation-code" -id "activation-id" -region
"region"
sudo start amazon-ssm-agent
```

## Amazon Linux 1

```
mkdir /tmp/ssm
curl https://amazon-ssm-region.s3.region.amazonaws.com/latest/linux_amd64/ssm-setup-cli
-o /tmp/ssm/ssm-setup-cli
sudo chmod +x /tmp/ssm/ssm-setup-cli
sudo /tmp/ssm/ssm-setup-cli -register -activation-code "activation-code" -id
"activation-id" -region "region"
```

## Amazon Linux 2, RHEL 7.x, Oracle Linux, CentOS 7.x, and SLES

```
mkdir /tmp/ssm
curl https://amazon-ssm-region.s3.region.amazonaws.com/latest/linux_amd64/ssm-setup-cli
-o /tmp/ssm/ssm-setup-cli
sudo chmod +x /tmp/ssm/ssm-setup-cli
sudo /tmp/ssm/ssm-setup-cli -register -activation-code "activation-code" -activation-id
"activation-id" -region "region"
```

## RHEL 8.x and CentOS 8.x

```
mkdir /tmp/ssm
curl https://amazon-ssm-region.s3.region.amazonaws.com/latest/linux_amd64/ssm-setup-cli
-o /tmp/ssm/ssm-setup-cli
sudo chmod +x /tmp/ssm/ssm-setup-cli
sudo /tmp/ssm/ssm-setup-cli -register -activation-code "activation-code" -activation-id
"activation-id" -region "region"
```

## Debian Server

```
mkdir /tmp/ssm
curl https://amazon-ssm-region.s3.region.amazonaws.com/latest/debian_amd64/ssm-setup-
cli -o /tmp/ssm/ssm-setup-cli
sudo chmod +x /tmp/ssm/ssm-setup-cli
sudo /tmp/ssm/ssm-setup-cli -register -activation-code "activation-code" -activation-id
"activation-id" -region "region"
```

## Raspberry Pi OS (formerly Raspbian)

```
mkdir /tmp/ssm
curl https://amazon-ssm-region.s3.region.amazonaws.com/latest/debian_arm/ssm-setup-cli
-o /tmp/ssm/ssm-setup-cli
sudo chmod +x /tmp/ssm/ssm-setup-cli
sudo /tmp/ssm/ssm-setup-cli -register -activation-code "activation-code" -activation-id
"activation-id" -region "region"
```

## Ubuntu

- **Using .deb packages**

```
mkdir /tmp/ssm
curl https://amazon-ssm-region.s3.region.amazonaws.com/latest/debian_amd64/ssm-setup-
cli -o /tmp/ssm/ssm-setup-cli
sudo chmod +x /tmp/ssm/ssm-setup-cli
sudo /tmp/ssm/ssm-setup-cli -register -activation-code "activation-code" -activation-
id "activation-id" -region "region"
```

- **Using Snap packages**

You don't need to specify a URL for the download, because the snap command automatically downloads the agent from the [Snap app store](https://snapcraft.io) at <https://snapcraft.io>.

On Ubuntu Server 20.10 STR & 20.04, 18.04, and 16.04 LTS, SSM Agent installer files, including agent binaries and config files, are stored in the following directory: `/snap/amazon-ssm-agent/current/`. If you make changes to any configuration files in this directory, then you must copy these files from the `/snap` directory to the `/etc/amazon/ssm/` directory. Log and library files haven't changed (`/var/lib/amazon/ssm`, `/var/log/amazon/ssm`).

```
sudo snap install amazon-ssm-agent --classic
```

```
sudo systemctl stop snap.amazon-ssm-agent.amazon-ssm-agent.service
sudo /snap/amazon-ssm-agent/current/amazon-ssm-agent -register -code "activation-
code" -id "activation-id" -region "region"
sudo systemctl start snap.amazon-ssm-agent.amazon-ssm-agent.service
```

### Important

The *candidate* channel in the Snap store contains the latest version of SSM Agent; not the stable channel. If you want to track SSM Agent version information on the candidate channel, run the following command on your Ubuntu Server 18.04 and 16.04 LTS 64-bit managed nodes.

```
sudo snap switch --channel=candidate amazon-ssm-agent
```

The command downloads and installs SSM Agent onto the hybrid-activated machine in your hybrid and multicloud environment. The command stops SSM Agent, and then registers the machine with the Systems Manager service. The machine is now a managed node. Amazon EC2 instances configured for Systems Manager are also managed nodes. In the Systems Manager console, however, your hybrid-activated nodes are distinguished from Amazon EC2 instances with the prefix "mi-".

Continue to [Install SSM Agent on hybrid Windows Server nodes](#).

## Setting up private key auto rotation

To strengthen your security posture, you can configure AWS Systems Manager Agent (SSM Agent) to automatically rotate the private key for your hybrid and multicloud environment. You can access this feature using SSM Agent version 3.0.1031.0 or later. Turn on this feature using the following procedure.

### To configure SSM Agent to rotate the private key for a hybrid and multicloud environment

1. Navigate to `/etc/amazon/ssm/` on a Linux machine or `C:\Program Files\Amazon\SSM` for a Windows machine.
2. Copy the contents of `amazon-ssm-agent.json.template` to a new file named `amazon-ssm-agent.json`. Save `amazon-ssm-agent.json` in the same directory where `amazon-ssm-agent.json.template` is located.

3. Find `Profile`, `KeyAutoRotateDays`. Enter the number of days that you want between automatic private key rotations.
4. Restart SSM Agent.

Every time you change the configuration, restart SSM Agent.

You can customize other features of SSM Agent using the same procedure. For an up-to-date list of the available configuration properties and their default values, see [Config Property Definitions](#).

## Deregister and reregister a managed node

You can deregister a hybrid-activated managed node by calling the [DeregisterManagedInstance](#) API operation from either the AWS CLI or Tools for Windows PowerShell. Here's an example CLI command:

```
aws ssm deregister-managed-instance --instance-id "mi-1234567890"
```

To remove the remaining registration information for the agent, remove the `IdentityConsumptionOrder` key in the `amazon-ssm-agent.json` file. Then run the following command:

```
amazon-ssm-agent -register -clear
```

You can reregister a machine after you deregister it. Use the following procedure to reregister a machine. After you complete the procedure, your managed node is displayed again in the list of managed nodes.

### To reregister a managed node on a non-EC2 Linux machine

1. Connect to your machine.
2. Run the following command. Be sure to replace the placeholder values with the Activation Code and Activation ID generated when you create a managed-node activation, and with the identifier of the Region you want to download the SSM Agent from.

```
echo "yes" | sudo /tmp/ssm/ssm-setup-cli -register -activation-code "activation-code" -activation-id "activation-id" -region "region"
```

## Troubleshooting SSM Agent installation on non-EC2 Linux machines

Use the following information to help you troubleshoot problems installing SSM Agent on hybrid-activated Linux machines in a [hybrid and multicloud](#) environment.

### You receive `DeliveryTimedOut` error

**Problem:** While configuring a machine in one AWS account as a managed node for a separate AWS account, you receive `DeliveryTimedOut` after running the commands to install SSM Agent on the target machine.

**Solution:** `DeliveryTimedOut` is the expected response code for this scenario. The command to install SSM Agent on the target node changes the node ID of the source node. Because the node ID has changed, the source node isn't able to reply to the target node that the command failed, completed, or timed out while executing.

### Unable to load node associations

**Problem:** After running the install commands, you see the following error in the SSM Agent error logs:

```
Unable to load instance associations, unable to retrieve
associations unable to retrieve associations error occurred in
RequestManagedInstanceRoleToken: MachineFingerprintDoesNotMatch:
Fingerprint doesn't match
```

You see this error when the machine ID doesn't persist after a reboot.

**Solution:** To solve this problem, run the following command. This command forces the machine ID to persist after a reboot.

```
umount /etc/machine-id
systemd-machine-id-setup
```

## Install SSM Agent on hybrid Windows Server nodes

This topic describes how to install SSM Agent on Windows Server machines for a [hybrid and multicloud](#) environment. If you plan to use non-EC2 Linux machines in a hybrid and multicloud environment, see the previous step, [Install SSM Agent on hybrid Linux nodes](#).

**⚠ Important**

This procedure is for non-EC2 (Amazon Elastic Compute Cloud) machines in hybrid and multicloud environment. To download and install SSM Agent on an EC2 instance for Windows Server, see [Manually installing and uninstalling SSM Agent on EC2 instances for Windows Server](#).

Before you begin, locate the Activation Code and Activation ID that were sent to you after you completed the hybrid activation earlier in [Create a hybrid activation to register nodes with Systems Manager](#). You specify the Code and ID in the following procedure.

**To install SSM Agent on non-EC2 Windows Server machines in a hybrid and multicloud environment**

1. Log on to a server or VM in your hybrid and multicloud environment.
2. If you use an HTTP or HTTPS proxy, you must set the `http_proxy` or `https_proxy` environment variables in the current shell session. If you aren't using a proxy, you can skip this step.

For an HTTP proxy server, set this variable:

```
http_proxy=http://hostname:port  
https_proxy=http://hostname:port
```

For an HTTPS proxy server, set this variable:

```
http_proxy=http://hostname:port  
https_proxy=https://hostname:port
```

3. Open Windows PowerShell in elevated (administrative) mode.
4. Copy and paste the following command block into Windows PowerShell. Replace each *example resource placeholder* with your own information. For example, the Activation Code and Activation ID generated when you create a hybrid activation, and with the identifier of the AWS Region you want to download SSM Agent from.

**Note**

Note the following important details:

- `ssm-setup-cli` supports a `manifest-url` option that determines the source where the agent is downloaded from. Don't specify a value for this option unless required by your organization.
- You can use the script provided [here](#) to validate the signature of `ssm-setup-cli`.
- When registering instances, only use the provided download link provided for `ssm-setup-cli`. `ssm-setup-cli` shouldn't be stored separately for future use.

*region* represents the identifier for an AWS Region supported by AWS Systems Manager, such as `us-east-2` for the US East (Ohio) Region. For a list of supported *region* values, see the **Region** column in [Systems Manager service endpoints](#) in the *Amazon Web Services General Reference*.

Additionally, `ssm-setup-cli` includes the following options:

- `version` - Valid values are `latest` and `stable`.
- `downgrade` - Reverts the agent to an earlier version.
- `skip-signature-validation` - Skips the signature validation during the download and installation of the agent.

## 64-bit

```
[System.Net.ServicePointManager]::SecurityProtocol = 'TLS12'  
$code = "activation-code"  
$id = "activation-id"  
$region = "us-east-1"  
$dir = $env:TEMP + "\ssm"  
New-Item -ItemType directory -Path $dir -Force  
cd $dir  
(New-Object System.Net.WebClient).DownloadFile("https://amazon-ssm-$region.s3.  
$region.amazonaws.com/latest/windows_amd64/ssm-setup-cli.exe", $dir + "\ssm-  
setup-cli.exe")  
./ssm-setup-cli.exe -register -activation-code="$code" -activation-id="$id" -  
region="$region"
```

```
Get-Content ($env:ProgramData + "\Amazon\SSM\InstanceData\registration")
Get-Service -Name "AmazonSSMAgent"
```

### 32-bit

```
"[System.Net.ServicePointManager]::SecurityProtocol = 'TLS12'"
$code = "activation-code"
$id = "activation-id"
$region = "us-east-1"
$dir = $env:TEMP + "\ssm"
New-Item -ItemType directory -Path $dir -Force
cd $dir
(New-Object System.Net.WebClient).DownloadFile("https://amazon-ssm-$region.s3.
$region.amazonaws.com/latest/windows_386/ssm-setup-cli.exe", $dir + "\ssm-setup-
cli.exe")
./ssm-setup-cli.exe -register -activation-code="$code" -activation-id="$id" -
region="$region"
Get-Content ($env:ProgramData + "\Amazon\SSM\InstanceData\registration")
Get-Service -Name "AmazonSSMAgent"
```

### 5. Press Enter.

#### Note

If the command fails, verify that you are running the latest version of AWS Tools for PowerShell.

The command does the following:

- Downloads and installs SSM Agent onto the machine.
- Registers the machine with the Systems Manager service.
- Returns a response to the request similar to the following:

```
Directory: C:\Users\ADMINI~1\AppData\Local\Temp\2
```

| Mode | LastWriteTime | Length | Name |
|------|---------------|--------|------|
| ---- | -----         | -----  | ---- |

```
d-----      07/07/2018   8:07 PM                ssm
{"ManagedInstanceID":"mi-008d36be46EXAMPLE","Region":"us-east-2"}

Status       : Running
Name         : AmazonSSMAgent
DisplayName  : Amazon SSM Agent
```

The machine is now a *managed node*. These managed nodes are now identified with the prefix "mi-". You can view managed nodes on the **Managed node** page in Fleet Manager, by using the AWS CLI command [describe-instance-information](#), or by using the API command [DescribeInstanceInformation](#).

## Setting up private key auto rotation

To strengthen your security posture, you can configure AWS Systems Manager Agent (SSM Agent) to automatically rotate the private key for a hybrid and multicloud environment. You can access this feature using SSM Agent version 3.0.1031.0 or later. Turn on this feature using the following procedure.

### To configure SSM Agent to rotate the private key for a hybrid and multicloud environment

1. Navigate to `/etc/amazon/ssm/` on a Linux machine or `C:\Program Files\Amazon\SSM` for a Windows Server machine.
2. Copy the contents of `amazon-ssm-agent.json.template` to a new file named `amazon-ssm-agent.json`. Save `amazon-ssm-agent.json` in the same directory where `amazon-ssm-agent.json.template` is located.
3. Find `Profile`, `KeyAutoRotateDays`. Enter the number of days that you want between automatic private key rotations.
4. Restart SSM Agent.

Every time you change the configuration, restart SSM Agent.

You can customize other features of SSM Agent using the same procedure. For an up-to-date list of the available configuration properties and their default values, see [Config Property Definitions](#).

## Deregister and reregister a managed node

You can deregister a managed node by calling the [DeregisterManagedInstance](#) API operation from either the AWS CLI or Tools for Windows PowerShell. Here's an example CLI command:

```
aws ssm deregister-managed-instance --instance-id "mi-1234567890"
```

To remove the remaining registration information for the agent, remove the `IdentityConsumptionOrder` key in the `amazon-ssm-agent.json` file. Then run the following command:

```
amazon-ssm-agent -register -clear
```

You can reregister a machine after you deregister it. Use the following procedure to reregister a machine as a managed node. After you complete the procedure, your managed node is displayed again in the list of managed nodes.

### To reregister a managed node on a Windows Server hybrid machine

1. Connect to your machine.
2. Run the following command. Be sure to replace the placeholder values with the Activation Code and Activation ID generated when you create a hybrid activation, and with the identifier of the Region you want to download the SSM Agent from.

```
'yes' | & Start-Process ./ssm-setup-cli.exe -ArgumentList @("-register", "-activation-code=$code", "-activation-id=$id", "-region=$region") -Wait  
Get-Content ($env:ProgramData + "\Amazon\SSM\InstanceData\registration")  
Get-Service -Name "AmazonSSMAgent"
```

## Managing edge devices with Systems Manager

This section describes the setup tasks that account and system administrators perform to enable configuration and management of AWS IoT Greengrass core devices. After you complete these tasks, users who have been granted permissions by the AWS account administrator can use AWS Systems Manager to configure and manage their organization's AWS IoT Greengrass core devices.

**Note**

- SSM Agent for AWS IoT Greengrass isn't supported on macOS and Windows 10. You can't use Systems Manager capabilities to manage and configure edge devices that use these operating systems.
- Systems Manager also supports edge devices that aren't configured as AWS IoT Greengrass core devices. To use Systems Manager to manage AWS IoT Core devices and non-AWS edge devices, you must configure them using a hybrid activation. For more information, see [Managing nodes in hybrid and multicloud environments with Systems Manager](#).
- To use Session Manager and Microsoft application patching with your edge devices, you must enable the advanced-instances tier. For more information, see [Turning on the advanced-instances tier](#).

**Before you begin**

Verify that your edge devices meet the following requirements.

- Your edge devices must meet the requirements to be configured as AWS IoT Greengrass core devices. For more information, see [Setting up AWS IoT Greengrass core devices](#) in the *AWS IoT Greengrass Version 2 Developer Guide*.
- Your edge devices must be compatible with AWS Systems Manager Agent (SSM Agent). For more information, see [Supported operating systems for Systems Manager](#).
- Your edge devices must be able to communicate with the Systems Manager service in the cloud. Systems Manager doesn't support disconnected edge devices.

**About setting up edge devices**

Setting up AWS IoT Greengrass devices for Systems Manager involves the following processes.

**Note**

For information about uninstalling SSM Agent from an edge device, see [Uninstall the AWS Systems Manager Agent](#) in the *AWS IoT Greengrass Version 2 Developer Guide*.

## Create an IAM service role for your edge devices

AWS IoT Greengrass core devices require an AWS Identity and Access Management (IAM) service role to communicate with AWS Systems Manager. The role grants AWS Security Token Service (AWS STS) [AssumeRole](#) trust to the Systems Manager service. You only need to create the service role once for each AWS account. You will specify this role for the `RegistrationRole` parameter when you configure and deploy the SSM Agent component to your AWS IoT Greengrass devices. If you already created this role while setting up non-EC2 nodes for a [hybrid and multicloud](#) environment, you can skip this step.

### Note

Users in your company or organization who will use Systems Manager on your edge devices must be granted permission in IAM to call the Systems Manager API.

### S3 bucket policy requirement

If either of the following cases are true, you must create a custom IAM permission policy for Amazon Simple Storage Service (Amazon S3) buckets before completing this procedure:

- **Case 1:** You're using a VPC endpoint to privately connect your VPC to supported AWS services and VPC endpoint services powered by AWS PrivateLink.
- **Case 2:** You plan to use an S3 bucket that you create as part of your Systems Manager operations, such as for storing output for Run Command commands or Session Manager sessions to an S3 bucket. Before proceeding, follow the steps in [Create a custom S3 bucket policy for an instance profile](#). The information about S3 bucket policies in that topic also applies to your service role.

### Note

If your devices are protected by a firewall and you plan to use Patch Manager, the firewall must allow access to the patch baseline endpoint `arn:aws:s3:::patch-baseline-snapshot-region/*`.

*region* represents the identifier for an AWS Region supported by AWS Systems Manager, such as `us-east-2` for the US East (Ohio) Region. For a list of supported

*region* values, see the **Region** column in [Systems Manager service endpoints](#) in the *Amazon Web Services General Reference*.

## AWS CLI

### To create an IAM service role for an AWS IoT Greengrass environment (AWS CLI)

1. Install and configure the AWS Command Line Interface (AWS CLI), if you haven't already.

For information, see [Installing or updating the latest version of the AWS CLI](#).

2. On your local machine, create a text file with a name such as `SSMService-Trust.json` with the following trust policy. Make sure to save the file with the `.json` file extension.

#### Note

Make a note of the name. You will specify it when you deploy SSM Agent to your AWS IoT Greengrass core devices.

```
{
  "Version": "2012-10-17",
  "Statement": {
    "Effect": "Allow",
    "Principal": {
      "Service": "ssm.amazonaws.com"
    },
    "Action": "sts:AssumeRole"
  }
}
```

3. Open the AWS CLI, and in the directory where you created the JSON file, run the [create-role](#) command to create the service role. Replace each *example resource placeholder* with your own information.

### Linux & macOS

```
aws iam create-role \
  --role-name SSMServiceRole \
```

```
--assume-role-policy-document file://SSMService-Trust.json
```

## Windows

```
aws iam create-role ^  
  --role-name SSMServiceRole ^  
  --assume-role-policy-document file://SSMService-Trust.json
```

4. Run the [attach-role-policy](#) command as follows to allow the service role you just created to create a session token. The session token gives your edge devices permission to run commands using Systems Manager.

### Note

The policies you add for a service profile for edge devices are the same policies used to create an instance profile for Amazon Elastic Compute Cloud (Amazon EC2) instances. For more information about the IAM policies used in the following commands, see [Configure instance permissions required for Systems Manager](#).

(Required) Run the following command to allow an edge device to use AWS Systems Manager service core functionality.

## Linux & macOS

```
aws iam attach-role-policy \  
  --role-name SSMServiceRole \  
  --policy-arn arn:aws:iam::aws:policy/AmazonSSMManagedInstanceCore
```

## Windows

```
aws iam attach-role-policy ^  
  --role-name SSMServiceRole ^  
  --policy-arn arn:aws:iam::aws:policy/AmazonSSMManagedInstanceCore
```

If you created a custom S3 bucket policy for your service role, run the following command to allow AWS Systems Manager Agent (SSM Agent) to access the buckets you specified in the policy. Replace *account\_ID* and *my\_bucket\_policy\_name* with your AWS account ID and your bucket name.

## Linux & macOS

```
aws iam attach-role-policy \  
  --role-name SSMSERVICE_ROLE \  
  --policy-arn arn:aws:iam::ACCOUNT_ID:policy/my_bucket_policy_name
```

## Windows

```
aws iam attach-role-policy ^  
  --role-name SSMSERVICE_ROLE ^  
  --policy-arn arn:aws:iam::ACCOUNT_ID:policy/my_bucket_policy_name
```

(Optional) Run the following command to allow SSM Agent to access AWS Directory Service on your behalf for requests to join the domain from edge devices. The service role needs this policy only if you join your edge devices to a Microsoft AD directory.

## Linux & macOS

```
aws iam attach-role-policy \  
  --role-name SSMSERVICE_ROLE \  
  --policy-arn arn:aws:iam::aws:policy/AmazonSSMDirectoryServiceAccess
```

## Windows

```
aws iam attach-role-policy ^  
  --role-name SSMSERVICE_ROLE ^  
  --policy-arn arn:aws:iam::aws:policy/AmazonSSMDirectoryServiceAccess
```

(Optional) Run the following command to allow the CloudWatch agent to run on your edge devices. This command makes it possible to read information on a device and write it to CloudWatch. Your service role needs this policy only if you will use services such as Amazon EventBridge or Amazon CloudWatch Logs.

```
aws iam attach-role-policy \  
  --role-name SSMSERVICE_ROLE \  
  --policy-arn arn:aws:iam::aws:policy/CloudWatchAgentServerPolicy
```

## Tools for PowerShell

### To create an IAM service role for an AWS IoT Greengrass environment (AWS Tools for Windows PowerShell)

1. Install and configure the AWS Tools for PowerShell (Tools for Windows PowerShell), if you haven't already.

For information, see [Installing the AWS Tools for PowerShell](#).

2. On your local machine, create a text file with a name such as `SSMService-Trust.json` with the following trust policy. Make sure to save the file with the `.json` file extension.

#### Note

Make a note of the name. You will specify it when you deploy SSM Agent to your AWS IoT Greengrass core devices.

```
{
  "Version": "2012-10-17",
  "Statement": {
    "Effect": "Allow",
    "Principal": {
      "Service": "ssm.amazonaws.com"
    },
    "Action": "sts:AssumeRole"
  }
}
```

3. Open PowerShell in administrative mode, and in the directory where you created the JSON file, run [New-IAMRole](#) as follows to create a service role.

```
New-IAMRole `
  -RoleName SSMServiceRole `
  -AssumeRolePolicyDocument (Get-Content -raw SSMService-Trust.json)
```

4. Use [Register-IAMRolePolicy](#) as follows to allow the service role you created to create a session token. The session token gives your edge devices permission to run commands using Systems Manager.

**Note**

The policies you add for a service role for edge devices in an AWS IoT Greengrass environment are the same policies used to create an instance profile for EC2 instances. For more information about the AWS policies used in the following commands, see [Configure instance permissions required for Systems Manager](#).

(Required) Run the following command to allow an edge device to use AWS Systems Manager service core functionality.

```
Register-IAMRolePolicy `
  -RoleName SSMSERVICE_ROLE `
  -PolicyArn arn:aws:iam::aws:policy/AmazonSSMManagedInstanceCore
```

If you created a custom S3 bucket policy for your service role, run the following command to allow SSM Agent to access the buckets you specified in the policy. Replace *account\_ID* and *my\_bucket\_policy\_name* with your AWS account ID and your bucket name.

```
Register-IAMRolePolicy `
  -RoleName SSMSERVICE_ROLE `
  -PolicyArn arn:aws:iam::account_ID:policy/my_bucket_policy_name
```

(Optional) Run the following command to allow SSM Agent to access AWS Directory Service on your behalf for requests to join the domain from edge devices. The service role needs this policy only if you join your edge devices to a Microsoft AD directory.

```
Register-IAMRolePolicy `
  -RoleName SSMSERVICE_ROLE `
  -PolicyArn arn:aws:iam::aws:policy/AmazonSSMDirectoryServiceAccess
```

(Optional) Run the following command to allow the CloudWatch agent to run on your edge devices. This command makes it possible to read information on a device and write it to CloudWatch. Your service role needs this policy only if you will use services such as Amazon EventBridge or Amazon CloudWatch Logs.

```
Register-IAMRolePolicy `
```

```
-RoleName SSMServiceRole `
-PolicyArn arn:aws:iam::aws:policy/CloudWatchAgentServerPolicy
```

## Configure your edge devices for AWS IoT Greengrass

Set up your edge devices as AWS IoT Greengrass core devices. The setup process involves verifying supported operating systems and system requirements, as well as installing and configuring the AWS IoT Greengrass Core software on your devices. For more information, see [Setting up AWS IoT Greengrass core devices](#) in the *AWS IoT Greengrass Version 2 Developer Guide*.

## Update the AWS IoT Greengrass token exchange role and install SSM Agent on your edge devices

The final step for setting up and configuring your AWS IoT Greengrass core devices for Systems Manager requires you to update the AWS IoT Greengrass AWS Identity and Access Management (IAM) device service role, also called the *token exchange role*, and deploy AWS Systems Manager Agent (SSM Agent) to your AWS IoT Greengrass devices. For information about these processes, see [Install the AWS Systems Manager Agent](#) in the *AWS IoT Greengrass Version 2 Developer Guide*.

After you deploy SSM Agent to your devices, AWS IoT Greengrass automatically registers your devices with Systems Manager. No additional registration is necessary. You can begin using Systems Manager capabilities to access, manage, and configure your AWS IoT Greengrass devices.

### Note

Your edge devices must be able to communicate with the Systems Manager service in the cloud. Systems Manager doesn't support disconnected edge devices.

## Creating an AWS Organizations delegated administrator for Systems Manager

When you set up an organization in AWS Organizations, you assign a management account to perform all administrative tasks for all AWS services. The management account user can assign a *delegated administrator account* only for Systems Manager to perform administrative tasks for Change Manager, Explorer, and OpsCenter. AWS Organizations is an account management service that you can use to create an organization and assign AWS accounts to manage these

accounts centrally. For information about AWS Organizations, see [AWS Organizations](#) in the *AWS Organizations User Guide*.

Change Manager, Explorer, and OpsCenter, capabilities of AWS Systems Manager, work with AWS Organizations to perform tasks on all member accounts of your organization. You can assign only one delegated administrator for all Systems Manager capabilities. The delegated administrator account must be a member of the organization to which it's assigned.

## Topics

- [Using a delegated administrator with Change Manager](#)
- [Using a delegated administrator with Explorer](#)
- [Using a delegated administrator with OpsCenter](#)
- [Using a delegated administrator with Quick Setup](#)

## Using a delegated administrator with Change Manager

Change Manager is an enterprise change management framework for requesting, approving, implementing, and reporting on operational changes to your application configuration and infrastructure.

If you use Change Manager across an organization, assign a delegated administrator account to manage change templates, approvals, and reporting for all member accounts. Using Quick Setup, you can set up Change Manager to use with an organization and select the delegated administrator account. If you use Change Manager with a single AWS account, the delegated administrator account isn't required.

By default, Change Manager displays all change-related tasks in the delegated administrator account. For instructions on configuring a delegated administrator while setting up Change Manager for an organization, see [Setting up Change Manager for an organization \(management account\)](#).

### Important

If you use Change Manager across an organization, we recommend always making changes from the delegated administrator account. Although you can make changes from other accounts in the organization, those changes won't be reported in or viewable from the delegated administrator account.

## Using a delegated administrator with Explorer

Explorer is a customizable operations dashboard that reports aggregated view of operations data (OpsData) for your AWS accounts, across AWS Regions.

You can configure a delegated administrator account for Systems Manager to aggregate Explorer data from multiple Regions and accounts by using resource data sync with AWS Organizations. A delegated administrator can search, filter, and aggregate Explorer data using the AWS Management Console, the AWS Command Line Interface (AWS CLI), or AWS Tools for Windows PowerShell.

When you use a delegated administrator account for Explorer, you limit the number of administrators who can create or delete multi-account and Region resource data syncs to an individual AWS account.

You can synchronize operations data across all AWS accounts in your organization by using Explorer. For information on how to assign a delegated administrator from Explorer, see [Configuring a delegated administrator for Explorer](#).

## Using a delegated administrator with OpsCenter

OpsCenter provides a central location where operations engineers and IT professionals can manage operational work items (OpsItems) related to AWS resources. If you want to use OpsCenter to manage OpsItems centrally across accounts, you must set up the organization in AWS Organizations.

Using Quick Setup for OpsCenter, you can assign a delegated administrator account and configure OpsCenter to manage OpsItems centrally. For more information, see [\(Optional\) Configure OpsCenter to manage OpsItems across accounts by using Quick Setup](#).

## Using a delegated administrator with Quick Setup

Quick Setup is a capability of Systems Manager that helps you to quickly configure frequently used AWS services and features with recommended best practices. You can configure a delegated administrator account for Quick Setup to help you deploy and manage configurations across accounts and Regions using AWS Organizations. A delegated administrator for Quick Setup can create, update, view, and delete configuration manager resources in your organization. Systems Manager registers a delegated administrator for Quick Setup as part of the setup process for the

integrated console experience. For more information, see [Setting up Systems Manager unified console for an organization](#).

## General setup for AWS Systems Manager

If you haven't already done so, sign up for an AWS account and create an administrative user.

### Sign up for an AWS account

If you do not have an AWS account, complete the following steps to create one.

#### To sign up for an AWS account

1. Open <https://portal.aws.amazon.com/billing/signup>.
2. Follow the online instructions.

Part of the sign-up procedure involves receiving a phone call and entering a verification code on the phone keypad.

When you sign up for an AWS account, an *AWS account root user* is created. The root user has access to all AWS services and resources in the account. As a security best practice, assign administrative access to a user, and use only the root user to perform [tasks that require root user access](#).

AWS sends you a confirmation email after the sign-up process is complete. At any time, you can view your current account activity and manage your account by going to <https://aws.amazon.com/> and choosing **My Account**.

### Create a user with administrative access

After you sign up for an AWS account, secure your AWS account root user, enable AWS IAM Identity Center, and create an administrative user so that you don't use the root user for everyday tasks.

#### Secure your AWS account root user

1. Sign in to the [AWS Management Console](#) as the account owner by choosing **Root user** and entering your AWS account email address. On the next page, enter your password.

For help signing in by using root user, see [Signing in as the root user](#) in the *AWS Sign-In User Guide*.

2. Turn on multi-factor authentication (MFA) for your root user.

For instructions, see [Enable a virtual MFA device for your AWS account root user \(console\)](#) in the *IAM User Guide*.

## Create a user with administrative access

1. Enable IAM Identity Center.

For instructions, see [Enabling AWS IAM Identity Center](#) in the *AWS IAM Identity Center User Guide*.

2. In IAM Identity Center, grant administrative access to a user.

For a tutorial about using the IAM Identity Center directory as your identity source, see [Configure user access with the default IAM Identity Center directory](#) in the *AWS IAM Identity Center User Guide*.

## Sign in as the user with administrative access

- To sign in with your IAM Identity Center user, use the sign-in URL that was sent to your email address when you created the IAM Identity Center user.

For help signing in using an IAM Identity Center user, see [Signing in to the AWS access portal](#) in the *AWS Sign-In User Guide*.

## Assign access to additional users

1. In IAM Identity Center, create a permission set that follows the best practice of applying least-privilege permissions.

For instructions, see [Create a permission set](#) in the *AWS IAM Identity Center User Guide*.

2. Assign users to a group, and then assign single sign-on access to the group.

For instructions, see [Add groups](#) in the *AWS IAM Identity Center User Guide*.

# Setting up AWS Systems Manager

The following topics describe how to set up the unified AWS Systems Manager console for AWS Organizations organizations and single AWS accounts.

## Topics

- [Setting up Systems Manager console access](#)
- [Setting up Systems Manager unified console for an organization](#)
- [Setting up Systems Manager unified console for a single account and Region](#)
- [Disabling the Systems Manager unified console](#)

## Setting up Systems Manager console access

To use AWS Systems Manager in the AWS Management Console, you must have the correct permissions configured.

For more information about how to create AWS Identity and Access Management policies and attach them to IAM identities, see [Create IAM policies](#) in the *IAM User Guide*

## Systems Manager onboarding policy

You can create an IAM policy like the one shown in the following example, and attach the policy to your IAM identities. This policy grants full access to onboard to and configure Systems Manager.

### Permissions details

This policy includes the following permissions.

- `ssm-quicksetup` – Allows principals to access all AWS Systems Manager Quick Setup actions.
- `ssm` – Allows principals access to Systems Manager Automation and Resource Explorer.
- `organizations` – Allows principals to read an organization's structure in AWS Organizations, and manage delegated administrators when they are onboarding to Systems Manager as an organization.
- `cloudformation` – Allows principals to manage their Quick Setup stacks.
- `iam` – Allows principals to manage IAM roles and policies that are required for Systems Manager onboarding.

```

## AWS Systems Manager console operator policy

You can create an IAM policy like the one shown in the following example, and attach the policy to your IAM identities. This policy grants full access to operate Systems Manager, and allow Systems Manager to run Automation documents for diagnosis and remediation.

### Permissions details

This policy includes the following permissions.

- `ssm` – Allows principals to access all Systems Manager APIs.
- `ssm-quicksetup` – Allows principals to manage their Quick Setup configurations.
- `ec2` – Allows Systems Manager to determine your enabled AWS Regions and Amazon EC2 instance status.
- `cloudformation` – Allows principals to read their Quick Setup stacks.

- `organizations` – Allows principals to read an organization's structure in AWS Organizations, and manage delegated administrators when they are onboarding to Systems Manager as an organization.
- `s3` – Allows principals to list and get objects in an Amazon S3 bucket for diagnosis, which is created during the Systems Manager onboarding process.
- `iam:PassRole` – Allows principals to pass roles to be assumed to Systems Manager when they run automations for diagnosis and remediation of unmanaged nodes.
- `iam:GetRole` – Allows principals to get specific role information for Quick Setup roles when they are working in Systems Manager.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ssm:*",
        "ssm-quicksetup:*"
      ],

        "arn:aws:iam::*:role/service-role/AWS-QuickSetup-*"
    ]
}
]
```

## AWS Systems Manager console operator read-only policy

You can create an IAM policy like the one shown in the following example, and attach the policy to your IAM identities. This policy grants read-only access to use Systems Manager.

- `ssm` – Allows principals access to Systems Manager read-only APIs.
- `ssm-quicksetup` – Allows principals to read their Quick Setup configurations.
- `cloudformation` – Allows principals to read their Quick Setup stacks.
- `iam:GetRole` – Allows principals to get specific role information for Quick Setup roles when they are using Systems Manager.
- `ec2:DescribeRegions` – Allows Systems Manager to determine your enabled AWS Regions.
- `organizations` – Allows principals to read an organization's structure in AWS Organizations when they are onboarding to Systems Manager as an organization.
- `s3` – Allows principals to list and get objects in an Amazon S3 bucket that is created during the Systems Manager onboarding process.

### Permissions details

This policy includes the following permissions.

```
{
  "Version": "2012-10-17",
  "Statement": [
```

```

{
  "Effect": "Allow",
  "Action": [
    "ssm:Describe*",
    "ssm:Get*",
    "ssm:List*",
    "ssm-quicksetup:List*",
    "ssm-quicksetup:Get*",
    "cloudformation:Describe*",
    "cloudformation:Get*",
    "cloudformation:List*",
    "iam:GetRole",
    "ec2:DescribeRegions",
    "organizations:Describe*",
    "organizations:List*"
  ],
  "Resource": "*"
},
{
  "Sid": "AllowKMSOperations",
  "Effect": "Allow",
  "Action": [
    "kms:Decrypt"
  ],
  "Resource": "arn:aws:kms:*:*:key/*",
  "Condition": {
    "StringEquals": {
      "aws:ResourceTag/SystemsManagerManaged": "true"
    },
    "ArnLike": {
      "kms:EncryptionContext:aws:s3:arn": "arn:aws:s3:::do-not-delete-ssm-
diagnosis-*"
    },
    "StringLike": {
      "kms:ViaService": "s3.*.amazonaws.com"
    },
    "Bool": {
      "aws:ViaAWSService": "true"
    }
  }
},
{
  "Effect": "Allow",
  "Action": [

```

```

        "s3:GetObject",
        "s3:ListBucket"
    ],
    "Resource": "arn:aws:s3::do-not-delete-ssm-diagnosis*",
    "Condition": {
        "StringEquals": {
            "aws:ResourceOrgId": "${aws:PrincipalOrgId}"
        }
    }
},
{
    "Effect": "Allow",
    "Action": [
        "s3:GetObject",
        "s3:ListBucket"
    ],
    "Resource": "arn:aws:s3::do-not-delete-ssm-diagnosis*",
    "Condition": {
        "StringEquals": {
            "aws:ResourceAccount": "${aws:PrincipalAccount}"
        }
    }
}
]
}

```

## Setting up Systems Manager unified console for an organization

The setup process for the Systems Manager unified console experience is completed from the AWS Management Console with just a few clicks. To set up Systems Manager for an AWS Organizations organization, you must have access to the management account for your organization and another account in your organization to use as a delegated administrator. Access to the management account is only required to enable or disable Systems Manager. To manage your nodes, you'll use the delegated administrator account. When managing nodes across an organization, Systems Manager uses various dependent services to set up and enhance the functionality of the unified console. As a result, Systems Manager must enable trusted access and register a delegated administrator account for the following services:

- AWS CloudFormation - Deploys resources required for Systems Manager to your accounts.

- AWS Resource Explorer - Searching and filtering EC2 instances in your accounts.
- AWS Systems Manager - Monitoring and troubleshooting the health of resources deployed for Systems Manager in your accounts.
- AWS Systems Manager Quick Setup - Deploys Quick Setup configurations required for Systems Manager to your accounts.

Before you begin setting up Systems Manager for an organization, make sure you're not already over the quota for delegated administrators for any of these dependent services. Otherwise, you won't be able to register the delegated administrator accounts necessary to enable Systems Manager. When you enable Systems Manager for an organization, every account in your organization is included. At this time, there is no provision for excluding accounts from the setting up process. When you enable Systems Manager, you can choose the AWS Regions you want to include. Only Regions that currently support the unified console experience for Systems Manager can be selected. To learn more about the Regions where the console experience is available, see [Supported AWS Regions](#).

#### Note

If you've created an aggregator index for Resource Explorer in a Region different than your home Region, Systems Manager demotes the current index. Then, Systems Manager promotes the local index in your home Region as the new aggregator index. During this time, only nodes for your home Region are displayed. This process can take up to 24 hours to complete.

The setup process for the Systems Manager console experience completes many prerequisite tasks for you. This includes creating and attaching instance profiles with the required IAM permissions to your nodes and more. Additionally, after the setup process completes you can select the **Diagnose and remediate** node task to automatically apply fixes to nodes that aren't reporting as managed by Systems Manager. This can include identifying issues such as network connectivity issues to the Systems Manager endpoints, and more.

### To set up Systems Manager for an organization

1. Log in to the management account for your organization.
2. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.

3. Enter the ID of the account you want to register as a delegated administrator.
4. After the delegated administrator account is successfully registered, log in to the delegated administrator account you just registered and return to the Systems Manager console to finish setting up Systems Manager.
5. Select **Enable Systems Manager**.
6. In the **Home Region** section, you determine a Region where you want Systems Manager to aggregate your node data. By default, Systems Manager selects the Region you're currently using. To choose a different home Region, change the console to the Region you want to use before you set up Systems Manager. Node data is replicated across accounts and Regions for your organization and stored in the home Region. The Region you choose can't be changed after Systems Manager is set up. To use a different Region as the home Region for your organization, you must disable the unified console and complete the setup process again. If your organization uses IAM Identity Center, you must select the same Region where you set up IAM Identity Center as your home Region.
7. In the **Regions** section, select the Regions where you want to enable Systems Manager.
8. Choose **Submit**.

Depending on the size of your organization, it can take an extended amount of time to set up the Systems Manager unified console experience.

## Setting up Systems Manager unified console for a single account and Region

To set up the Systems Manager unified console experience for a single AWS account and AWS Region you don't need to use Organizations or register a delegated administrator account. The setup process for the Systems Manager console experience completes many prerequisite tasks for you. This includes creating and attaching instance profiles with the required IAM permissions to your nodes and more. Additionally, after the setup process completes you can select the **Diagnose and remediate** node task to automatically apply fixes to nodes that aren't reporting as managed by Systems Manager. This can include identifying issues such as network connectivity issues to the Systems Manager endpoints, and more.

## To set up Systems Manager for a single account and Region

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. Select **Enable Systems Manager**.

## Disabling the Systems Manager unified console

To disable the Systems Manager unified console for an organization, you'll need access to the account you registered as a delegated administrator for Systems Manager. After logging in to the delegated administrator account for your organization, you can disable the setup for your organization in the **Settings** section of the unified console. When you disable the unified console setup for your organization, Systems Manager deletes the resources created during the setting up process. Disabling the setup for your organization doesn't revoke trusted access or deregister the delegated administrator accounts for dependent services. The following procedure describes how to disable the setup for the unified console.

### To disable the setup for the Systems Manager unified console

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. Select **Settings** in the navigation pane.
3. Select **Disable**. You must confirm that you want to disable the setup for your organization. This action deletes the resources created for the unified console and can't be undone.

If you're unable to access the delegated administrator account for Systems Manager and want to disable the setup for the unified console, you can also do so from the management account for your organization. Using the AWS CLI or SDK, call the `DeleteConfigurationManager` API operation and pass the `ManagerArn` value for the organization setup in your account. The format for the manager ARN used to set up the unified console is as follows: `arn:aws:ssm-quicksetup:account-id:configuration-manager/AWSQuickSetupType-SSM`.

# Complete node tasks with AWS Systems Manager

The following topics describe how to complete common node tasks using the integrated AWS Systems Manager console for an AWS Organizations organization and single AWS accounts.

## Topics

- [Perform a node task with Systems Manager](#)
- [Reviewing node insights](#)
- [Exploring nodes](#)
- [Diagnosing and remediating](#)
- [Adjusting Systems Manager settings](#)

## Perform a node task with Systems Manager

Use this tutorial to get started with AWS Systems Manager. You'll learn how to launch an Amazon Elastic Compute Cloud (Amazon EC2) instance that is managed by Systems Manager, and how to connect to the managed instance.

Because Systems Manager is a collection of multiple capabilities, no single walkthrough or tutorial can introduce the entire service. This tutorial provides an introduction to some of the capabilities.

## Prerequisites

Before you begin, be sure that you've completed the steps in [Managing EC2 instances with Systems Manager](#).

## Launch an instance using an AMI with SSM Agent preinstalled

You can launch an Amazon EC2 instance using the AWS Management Console as described in the following procedure. This tutorial is intended to help you launch your first managed instance quickly, so it doesn't cover all possible options.

### To launch an instance

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.

2. From the EC2 console dashboard, in the **Launch instance** box, choose **Launch instance**, and then choose **Launch instance** from the options that appear.
3. For **Name and tags**, for **Name**, enter a descriptive name for your instance.
4. For **Application and OS Images (Amazon Machine Image)**, do the following:
  - a. Choose the **Quick Start** tab, and then choose Amazon Linux. This is the operating system (OS) for your instance.
  - b. For **Amazon Machine Image (AMI)**, choose an HVM version of Amazon Linux 2.
5. For **Instance type**, from the **Instance type** list, choose the hardware configuration for your instance. Choose the `t2.micro` instance type, which is selected by default. The `t2.micro` instance type is eligible for the AWS Free Tier. In AWS Regions where `t2.micro` is unavailable, you can use a `t3.micro` instance under the Free Tier. For more information, see [AWS Free Tier](#).
6. For **Key pair (login)**, for **Key pair name**, choose a key pair.
7. For **Network settings**, choose **Edit**. For **Security group name**, notice that the wizard created and selected a security group for you. You can use this security group, or alternatively you can select a security group that you created previously using the following steps:
  - a. Choose **Select existing security group**.
  - b. From **Common security groups**, choose your security group from the list of existing security groups.
8. If you aren't using Default Host Management Configuration, expand the **Advanced details** section, and for **IAM instance profile**, choose the instance profile that you created when getting set up in [Configure instance permissions required for Systems Manager](#).
9. Keep the default selections for the other configuration settings for your instance.
10. Review a summary of your instance configuration in the **Summary** pane. When you're ready, choose **Launch instance**.
11. A confirmation page informs you that your instance is launching. Choose **View all instances** to close the confirmation page and return to the console.
12. On the **Instances** screen, you can view the status of the launch. It takes a short time for an instance to launch.
13. It can take a few minutes for the instance to show as managed and be ready for you to connect to it. To check that your instance passed its status checks, view this information in the **Status check** column.

## Connect to your managed instance using Systems Manager

### To connect to your managed instance

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Fleet Manager**.
3. Choose the button next to the instance that you want to connect to.
4. In the **Node actions** menu, choose **Start terminal session**.
5. Select **Connect**.

### Clean up your instance

If you're done working with the managed instance that you created for this tutorial, terminate it. Terminating an instance effectively deletes it.

### To terminate your instance

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances**. In the list of instances, select the instance.
3. Choose **Instance state, Terminate instance**.
4. Choose **Terminate** when prompted for confirmation.

Amazon EC2 shuts down and terminates your instance. After your instance is terminated, it remains visible on the console briefly, and then the entry is deleted automatically. You can't remove the terminated instance from the console display yourself.

## Reviewing node insights

You can gain insights into the overall status of managed nodes and unmanaged EC2 instances in your organization or account by using the new Systems Manager console experience.

Systems Manager provides a visual overview into your managed nodes and EC2 instances that are not yet managed by Systems Manager. (A managed node is any machine configured for use with Systems Manager in [hybrid and multicloud](#) environments. For information about supported machine types, see [Supported machine types in hybrid and multicloud environments](#).)

This overview is provided through individual report boxes, called *widgets*, which feature interactive pie charts and other graphics.

## Before you begin

In order to review node insights, you must first onboard your organization or account to the new Systems Manager experience. For more information, see [Setting up AWS Systems Manager](#).

After onboarding, open the [Systems Manager console](#) and choose **Review node insights**.

The following image shows the individual report boxes, called *widgets*, which are available on the **Review node insights** page.

The display supports widgets that provide you with the following information.

## Node summary

Indicates how many EC2 instances in your organization or account aren't currently managed nodes, and how many managed nodes are in your organization's or account's fleet.

## Managed node types

Indicates how many managed nodes in your fleet are EC2 instances and how many are other server types, including servers on your own premises (on-premises servers), AWS IoT Greengrass core devices, AWS IoT and non-AWS edge devices, and virtual machines (VMs), including VMs in other cloud environments. You can hover over the **Node types** graphic to access links to more details in the **Explore nodes** page.

For more information about AWS support for hybrid and multicloud environments, see [AWS Solutions for Hybrid and Multicloud](#).

## SSM Agent versions

Provides information about installations of AWS Systems Manager Agent (SSM Agent) in your fleet. SSM Agent is Amazon software that runs on your managed nodes. SSM Agent makes it possible for Systems Manager to update, manage, and configure these resources. The agent processes requests from the Systems Manager service in the AWS Cloud, and then runs them as specified in the request.

For managed nodes in your fleet, this widget reports on the SSM Agent versions in your fleet, from newest to oldest. You can hover over the **SSM Agent versions** graphic to access links to more details in the **Explore nodes** page.

For more information about SSM Agent, see [Working with SSM Agent](#).

## Managed node operating systems

Provides a breakdown of the percentage of each operating system on managed nodes in your fleet. You can hover over the **Managed nodes by operating systems** graphic to access links to more details in the **Explore nodes** page.

You can customize widget layout on the **Review node insights** page by using a drag-and-drop capability, and by removing and adding widgets to the display.

Use information in the following topics to help you work with the Systems Manager node insights widgets.

### Topics

- [Adding or removing widgets from the Review node insights page](#)
- [Rearranging widgets in the Review node insights page](#)

## Adding or removing widgets from the Review node insights page

You can customize the layout in the Systems Manager **Review node insights** page by adding and removing widgets.

### Note

By default, the page displays all available widgets.

### To add or remove widgets from the Review node insights page

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the left navigation, choose **Review node insights**.
3. To remove a widget from the display, do the following:
  - a. Choose the ellipsis menu  
()  
for the widget.
  - b. Choose **Remove widget**.
4. To add a widget to the display, do the following:
  - a. Choose **Add widgets**.
  - b. In the **Add widgets** pane, click and hold the drag handle  
()  
of the widget to add to the display.
  - c. Drag the widget and drop it into the main pane.

## Rearranging widgets in the Review node insights page

You can customize the layout in the **Review node insights** page by rearranging widgets.

### To rearrange widgets in the Review node insights page

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.

2. In the navigation pane, choose **Review node insights**.
3. To customize the widget layout, choose a widget that you want to move. Click and hold the drag handle

of the widget and then drag it to its new location.

4. Repeat this process for each widget that you want to reposition.

If you decide that you don't like the new layout, choose **Reset to default layout** to move all widgets back to their original location.

## Exploring nodes

You can use the **Explore nodes** page in Systems Manager to review details of managed nodes in your organization or account according to the criteria you specify in filters. You can also use Systems Manager integration with Amazon Q Developer (Amazon Q), an AWS generative AI solution, to search using text prompts.

### Before you begin

In order to use the **Explore nodes** feature, you must first onboard your organization or account to the new Systems Manager experience. For more information, see [Setting up Systems Manager unified console for an organization](#).

After onboarding, open the [Systems Manager console](#) and choose **Explore nodes**.

#### Note

If you've created an aggregator index for Resource Explorer in a Region different than your home Region, Systems Manager demotes the current index. Then, Systems Manager promotes the local index in your home Region as the new aggregator index. During this time, only nodes for your home Region are displayed. This process can take up to 24 hours to complete.

### Topics

- [Exploring nodes using console filters](#)
- [Exploring nodes using text prompts in Amazon Q](#)

- [Viewing individual node details and taking action on a node](#)
- [Downloading or exporting a managed node report](#)
- [Managing node report content and appearance](#)

## Exploring nodes using console filters

In the Systems Manager console, you can then group your managed nodes according to the following views:

### All nodes (No filter)

Lists all managed nodes in your organization or account.

#### Explore nodes (56)

Explore details about managed nodes in your organization.

### Node types

Provides tabs for viewing data separately for Amazon Elastic Compute Cloud (Amazon EC2) instances and other machine types, including servers on your own premises (on-premises servers), AWS IoT Greengrass core devices, AWS IoT and non-AWS edge devices, and virtual machines (VMs), including VMs in other cloud environments.

In addition, for each of these views, you can further refine the list of nodes reported by choosing to view only nodes for a certain property, such as node status, AWS account ID, organization unit ID, and more.

You can customize the report display by choosing which of the available data columns are displayed in the **Explore nodes** page. You can also download reports in CSV or JSON formats, or export reports to Amazon S3 in CSV format.

## Topics

- [Choosing a filter view for managed node summaries](#)

## Choosing a filter view for managed node summaries

The **Explore nodes** page in Systems Manager lets you view aggregated data about your fleet according to a number of available filter views.

### To choose a filter view for managed node summaries

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Explore nodes**.
3. For **Filter view**, select one of the filter options and optionally further refine the report:
  - **Managed nodes** – In the search  box, you can select a property and delimiter, such as Node type = Managed EC2 instances.
  - **Operating systems** – In the **Filter Operating system versions** list, you can select an OS version number. In the search  box, you can select a property and delimiter, such as Node type = Managed EC2 instances.
  - **SSM Agent versions** – In the **Filter Operating systems** list, you can select an OS name. In the search  box, you can select a property and delimiter, such as Node type = Managed EC2 instances.
  - **Node types** – In the **Filter Operating systems** list, you can select an OS name. In the search  box, you can select a property and delimiter, such as Node type = Managed EC2 instances.

After optionally filtering the list, you can view details about a specific managed node by choosing its ID in the **Node ID** column. From that detailed view, you can perform a number of actions on the node.

## Exploring nodes using text prompts in Amazon Q

Using Systems Manager integration with Amazon Q Developer, you can use text prompts to view information created by generative AI about your managed nodes.

Amazon Q Developer is a generative AI-powered conversational assistant that can help you to understand, build, extend, and operate AWS applications. To accelerate your building on AWS, the model that powers Amazon Q is augmented with high-quality AWS content to produce more complete, actionable, and referenced answers. For more information, see [What is Amazon Q Developer?](#) in the *Amazon Q Developer User Guide*.

The integration between Systems Manager and Amazon Q lets you quickly get visibility and control over large, distributed environments across multiple AWS accounts and Regions. You can use natural language querying to quickly search node data, and then identify issues and take action faster.

When you ask a natural language question about managed nodes or managed instances, Amazon Q uses the Systems Manager `ListNodes` action and creates filters based on your textual input to retrieve results.

For example, say that you give Amazon Q the following prompt:

**List my managed nodes running Red Hat Enterprise Linux 9.2**

Amazon Q determines what filters to include in a request, and then runs a query similar to the following:

```
aws ssm list-nodes \  
  --filters Key=PlatformName,Values='Red Hat Enterprise Linux',Type=Equal  
  Key=PlatformVersion,Values=9.2,Type=Equal
```

Amazon Q then generates a report about Red Hat Enterprise Linux instances in your account, listing information such as the number of instances, their IDs, and their Regions.

You can also view a JSON summary of each instance's details, as well open a link to view the entire lists of EC2 instances or managed nodes in the Systems Manager **Explore nodes** page. The **Explore nodes** displays results that match the filter criteria you included in your prompt. From there, you can change or refine the filters for your request, as described in [Exploring nodes](#).

## Learning to craft effective prompts to ask Amazon Q about your fleet

The better quality of the question, or the prompt, that you give to Amazon Q, the better the result it provides you with.

### Tips for query prompts

Keep in mind the following tips when querying Amazon Q about your fleet:

1. To help improve the accuracy of your results, use the terms "managed nodes" and "managed instances" in your prompts instead of just "nodes" and "instances".
2. To query for results across multiple accounts that are part of an *organization*, as configured in AWS Organizations, you must be logged into the delegated administrator account in the designated home Region.
3. In the delegated administrator account, use terms to help Amazon Q understand that you are asking about nodes and instances across the organization by specifically using terms such as "in my organization" or "in my account 123456789012".

## Sample questions for Amazon Q

In the following table, we provide sample questions demonstrate some ways you can create queries of Amazon Q that lead to better results.

We also provide examples of the filters Amazon Q will apply when running the [ListNodes](#) command, which are generated from the content of your prompt.

| Sample natural language question  | Amazon Q applied filters |
|-----------------------------------|--------------------------|
| Show me my Windows managed nodes. | PlatformType = Windows   |

| Sample natural language question  | Amazon Q applied filters  |
|---|---|
| <b>List my managed instances in account 123456789012.</b>   | AccountId = 123456789012  |
| <b>Show me all managed nodes running Amazon Linux 1 across my organization.</b>   | PlatformName = Amazon Linux<br>PlatformVersion = 1  |
| <b>Show me all managed instances running Microsoft Windows Server 2019 Datacenter in my organization.</b>                                   | PlatformName = Microsoft Windows Server 2019 Datacenter   |
| <b>Can you show me all managed nodes with SSM Agent version 3.3.1142.0?</b>   | AgentType = amazon-ssm-agent<br>AgentVersion = 3.3.1142.0   |
| <b>List all Amazon Linux 2 managed instances in account 123456789012 that have SSM Agent version 3.3.1230.0.</b>                            | PlatformName = Amazon Linux<br>PlatformVersion = 2<br>AccountId = 123456789012<br>AgentType = amazon-ssm-agent<br>AgentVersion = 3.3.1230.0 |
| <b>What Microsoft Windows Server 2008 R2 Enterprise managed nodes are running in the eu-central-1 region across my entire organization?</b> | PlatformName = Microsoft Windows Server 2008 R2 Enterprise<br>Region = eu-central-1   |
| <b>Show me all managed instances running CentOS Linux 7 in ou-d6ty-gxdma6vm.</b>  | PlatformName = CentOS Linux<br>PlatformVersion = 7<br>OrganizationalUnitId = ou-d6ty-gxdma6vm   |
| <b>What Ubuntu managed instances are in account 123456789012?</b>   | PlatformName = Ubuntu<br>AccountId = 123456789012   |

| Sample natural language question  | Amazon Q applied filters   |
|---|--|
| <b>List my Linux managed instances.</b>   | PlatformType = Linux   |
| <b>Find my macOS managed nodes.</b>   | PlatformType = macOS   |
| <b>Show me all Amazon Linux managed nodes in my org.</b>                            | PlatformName = Amazon Linux  |
| <b>List managed nodes running Amazon Linux 2 .</b>                                  | PlatformName = Amazon Linux<br>PlatformVersion = 2                           |
| <b>List the managed nodes with Ubuntu 16.04 in account 123456789012.</b>            | PlatformName = Ubuntu<br>PlatformVersion = 16.04<br>AccountId = 123456789012 |
| <b>Find all managed nodes that have an SSM Agent version that is not 3.3.987.0.</b> | AgentType = amazon-ssm-agent<br>AgentVersion != 3.3.987.0                    |
| <b>List all managed instances that are not running a Linux operating system.</b>    | PlatformType != Linux  |

## Supported operating system names and versions for prompts

When you are asking Amazon Q about the managed nodes in your account, it's helpful to provide the name of an operating system as its labeled in Systems Manager. You can also provide version numbers to further narrow down your results. For example, as represented in the following tables, you could ask for results specifically about **macOS 14.5**, **Microsoft Windows Server 2019 Datacenter**, and **AlmaLinux 9.2 through 9.4**, to name just a few examples.

These lists might not be exhaustive and are offered as examples only.

**macOS**

| Platform name | Version numbers   |
|---------------|---|
| macOS         | 11.6.7, 11.7.10, 12.6.6, 12.7.6, 13.2, 13.4, 13.7, 14.1, 14.5, 14.6.1, 15.0 |

**Windows**

| Releases                                    | Version numbers |
|---|-----------------|
| Microsoft Windows Server 2008 Enterprise    | 6.0.6003        |
| Microsoft Windows Server 2008 R2 Datacenter | 6.1.7601        |
| Microsoft Windows Server 2008 R2 Enterprise | 6.1.7601        |
| Microsoft Windows Server 2008 R2 Standard   | 6.1.7601        |
| Microsoft Windows Server 2012 R2 Datacenter | 6.3.9600        |
| Microsoft Windows Server 2012 R2 Standard   | 6.3.9600        |
| Microsoft Windows Server 2012 Standard      | 6.2.9200        |
| Microsoft Windows Server 2016 Datacenter    | N/A             |
| Microsoft Windows Server 2016 Standard      | 10.0.14393      |
| Microsoft Windows Server 2019 Datacenter    | N/A             |
| Microsoft Windows Server 2019 Standard      | N/A             |
| Microsoft Windows Server 2022 Datacenter    | N/A             |
| Microsoft Windows Server 2022 Standard      | 10.0.20348      |

## Linux

| Platform names                  | Version numbers   |
|---------------------------------|---|
| AlmaLinux                       | 8.10, 9.2, 9.3, 9.4   |
| Amazon Linux 2                  | 2.0 and greater   |
| Amazon Linux 2023               | 2023.0.20230315.0 and greater   |
| Amazon Linux                    | 2015.03, 2015.09, 2016.03, 2016.09, 2017.03, 2017.09, 2018.03   |
| BottleRocket                    | 1.14.3, 1.16.1, 1.18.0, 1.19.1, 1.19.2, 1.19.5, 1.20.0, 1.20.1, 1.20.2, 1.20.3, 1.20.5, 1.21.1, 1.23.0, 1.24.0, 1.24.1, 1.25.0, 1.26.1,                                   |
| CentOS                          | 6.7, 6.8, 6.9 (Final), 6.10, 6.10 (Final)   |
| CentOS Linux                    | 7, 7.2.1511, 7.2.1511 (Core), 7.3.1611, 7.3.1611 (Core), 7.4.1708, 7.5.1804, 7.5.1804 (Core), 7.6.1810, 7.7.1908, 7.8.2003, 7.9.2009, 7.9.2009 (Core), 8.2.2004, 8.5.2111 |
| CentOS Stream                   | 8, 9  |

| Ubuntu                          | 14.04, 16.04, 18.04, 20.04, 22.04, 24.04  |

## Exploring managed nodes using Amazon Q

Systems Manager integration with Amazon Q Developer lets you ask questions about managed nodes in your fleet from anywhere in the AWS Management Console where the Amazon Q interface is available.

Before asking questions of Amazon Q, review the information in [Learning to craft effective prompts to ask Amazon Q about your fleet](#) for tips on creating effective prompts.

### To explore managed nodes using Amazon Q

1. From anywhere in the AWS Management Console, choose the Amazon Q icon  ).
2. In the prompt field at the bottom of the Amazon Q pane, ask a question about managed nodes in your account or organization.
3. Examine information about specific nodes, or choose **Open AWS Systems Manager console** to continue exploring.

## Viewing individual node details and taking action on a node

From a list in the **Explore nodes** page in Systems Manager, you can select an individual node in order to view comprehensive details about the machine or perform a variety of actions on the node. The **General** page in the detail page presents comprehensive information about the node.

### To view individual node details and take action on a node

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Explore nodes**.
3. (Optional) Follow the steps in [Choosing a filter view for managed node summaries](#) to refine the list of managed nodes displayed for your organization or account.
4. In the **Node ID** column, choose the linked ID of a node.
5. To view more details about the node, in the left navigation, in the **Properties** list, choose a property to view more information about:
  - **Tags** – View a list of tags applied to the node. You can also add or remove tags.

- **Inventory** – Choose an inventory type, such as **AWS:Application** or **AWS:Network**, to view inventory details for the node.
  - **Associations** – View details about all State Manager associations applied to the node, including details such as status and associated SSM document name.
  - **Patches** – View summary information about patches and patch status for the node.
  - **Configuration compliance** – View compliance details for the node, such as compliance status and compliance issue severity.
6. To take actions on the node, use the following options in the **Node actions** menu:

 **Note**

These actions are available only for managed nodes in the AWS account and Region you are currently working in. For managed nodes you might have access to in other accounts or Regions, you can instead access a **Properties** list.

- **Connect, Start terminal session** – Connect to the node using [AWS Systems Manager Session Manager](#).
- **Tools**
  - **View file system** – Browse the contents of the node's directory structure. Add, rename, and remove directories. Cut or copy and paste files.
  - **View performance counters** – View performance information about the node such as CPU utilization, network traffic, and other utilization types.
  - **Managed processes** – View information about resource usage on the node. Start or stop processes on the node.
  - **Manage users and groups** – View, add, or delete user accounts and user groups on the node.
  - **Execute run command** – Use [AWS Systems Manager Run Command](#) to manage the configuration of the node. Run Command uses [Systems Manager documents](#) to perform on-demand changes such as updating applications or running Linux shell scripts and Windows PowerShell commands.
  - **Patch nodes** – Use the **Patch now** feature in [AWS Systems Manager Patch Manager](#) to run an on-demand patching operation on the node from the console.

**Note**

The preceding tasks can also be initiated from the **Tools** menu in the left navigation.

- **Node settings**
  - **Add tags** – Apply additional tag key-value pairs to the node.
  - **Reset node user password** – Set a new password for a specified user on the node.
  - **Modify IAM role** – Change the IAM role that's associated with the node. Create a new IAM role to attach to the node.

## Downloading or exporting a managed node report

You can use the Systems Manager **Explore nodes** feature to view filtered or unfiltered lists of managed nodes for your AWS organization or account in the Systems Manager console. For cases where you want to view the data offline or process it in another application, you can save the report as a CSV or JSON file.

Depending on the size of the report, you're prompted to download the report to your local machine or export it to an Amazon S3 bucket. Reports are saved to S3 buckets in CSV format only.

### To download or export a managed node report

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Explore nodes**.
3. (Optional) Follow the steps in [Choosing a filter view for managed node summaries](#) to refine the list of managed nodes displayed for your organization or account.
4. Choose **Report**  
([↓](#)).
5. If the **Download report** dialog box is displayed, do the following:
  - a. For **File name**, enter a name for the file. We recommend specifying a name that represents the scope of the report, such as `all-organization-nodes` or `ec2-instances-out-of-date-agent`.

- b. For **Included columns**, specify whether to include columns for all available node details, or only those you've selected for your current display.

 **Tip**

For information about managing the columns in your report display, see [Managing node report content and appearance](#).

- c. For **File format**, select **CSV** or **JSON**, depending on how you will use the file.
- d. For **Spreadsheet heading**, to include a column headings row in a CSV file, select **Include row of column names**.
- e. Choose **Download**.

The report is saved to the default download location according to your browser's settings.

6. If the **Export to Amazon S3** dialog box is displayed, do the following:
  - a. For **S3 URI**, enter the URI for the bucket to export the report to.

 **Tip**

To view a list of your buckets in the Amazon S3 console, choose **View**. To select from a list of buckets in your account, choose **Browse S3**.

- b. For **Authorization method**, specify the service role to use to provide permissions for exporting the report to the bucket.

If you choose to let Systems Manager create the role for you, it provides all needed permissions and trust statements for the operation.

If you want to use or create your own role, the role must include the required permissions and trust statements. For information about creating this role, see [Creating a custom service role to export diagnosis reports to S3](#).

- c. Choose **Submit**.

## Creating a custom service role to export diagnosis reports to S3

When you are viewing filtered or unfiltered lists of managed nodes for your AWS organization or account in the Systems Manager **Explore nodes** page, you can export the list as a report to an Amazon S3 bucket as a CSV file.

To do so, you must specify a service role with the necessary permissions and trust policy for the operation. You can choose for Systems Manager to create the role for you during the process of downloading the report. Optionally, you can create the role and its required policy yourself.

### To create a custom service role to export diagnosis reports to S3

1. Follow the steps in [Creating policies using the JSON editor](#) in the *IAM User Guide*.
  - Use the following for the policy content, making sure to replace the *placeholder values* with your own information.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "s3:GetObject",
        "s3:PutObject"
      ],
      "Resource": "arn:aws:s3:::s3-bucket-name/*",
      "Condition": {
        "StringEquals": {
          "aws:ResourceAccount": "account-id"
        }
      }
    },
    {
      "Effect": "Allow",
      "Action": [
        "s3:GetBucketAcl",
        "s3:ListBucket",
        "s3:PutLifecycleConfiguration",
        "s3:GetLifecycleConfiguration"
      ],
      "Resource": "arn:aws:s3:::s3-bucket-name",
      "Condition": {
```

```

    "StringEquals": {
      "aws:ResourceAccount": "account-id"
    }
  },
  {
    "Effect": "Allow",
    "Action": [
      "ssm:ListNodes"
    ],
    "Resource": "*"
  }
]
}

```

- Give the policy a name to help you recognize it easily in the next step.
2. Follow the steps in [Creating an IAM role using a custom trust policy \(console\)](#) in the *IAM User Guide*.
    - For step 4, enter the following trust policy, making sure to replace the *placeholder values* with your own information.

```

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "SSMAssumeRole",
      "Effect": "Allow",
      "Principal": {
        "Service": "ssm.amazonaws.com"
      },
      "Action": "sts:AssumeRole",
      "Condition": {
        "StringEquals": {
          "aws:SourceAccount": "account-id"
        }
      }
    }
  ]
}

```

3. For step 10, choose **Step 2: Add permissions** and select the name of the policy you created in the previous step.

After you create the role, you can select it when following the steps in [Downloading or exporting a managed node report](#).

## Managing node report content and appearance

You can use the Systems Manager **Explore nodes** feature to view filtered or unfiltered lists of managed nodes for your AWS organization or account in the Systems Manager console. You can choose from over a dozen fields to include in your lists of nodes, such as **Node ID**, **Operating system name**, **Region**, and more. You can also reorder the columns for your lists and reports and change how the list is displayed in the console.

### To manage node report content and appearance

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Explore nodes**.
3. In the **Nodes** area, choose the preferences gear icon  ).
4. In the **Preferences** dialog box, do the following:
  - a. For **Page size**, choose how many rows are included in each console view display, **10**, **25**, or **50**.
  - b. For **Wrap lines**, select the box to display all content of a cell in the available column width.
  - c. For **Striped rows**, select the box to display alternating rows of clear and shaded backgrounds.
  - d. For **Select visible content**, do the following:
    - Turn on or off individual columns for your list display and reports.
    - To change the order of columns, click and hold the drag handle  ) of a column name and drag it up or down in the list.
5. Choose **Confirm**.

## Diagnosing and remediating

Using the new Systems Manager experience, you can identify problems across your fleet in a single diagnosis operation. For organizations, you can then attempt remediation on all or only select targets using a single Automation operation. For an organization, as a delegated account administrator, you can select targets across all accounts and Regions. If you are working in a single account, you can select targets in a single Region at a time.

Systems Manager can diagnose and help you remediate several types of deployment failures, as well as drifted configurations. Systems Manager can also identify Amazon Elastic Compute Cloud (Amazon EC2) instances in your account or organization that Systems Manager isn't able to treat as a *managed node*. The EC2 instance diagnosis process can identify issues related to misconfigurations for a virtual private cloud (VPC), in a Domain Name Service (DNS) setting, or in an Amazon Elastic Compute Cloud (Amazon EC2) security group.

### Note

Systems Manager supports both EC2 instances and other machine types in a [hybrid and multicloud](#) environment as *managed nodes*. To be a managed node, AWS Systems Manager Agent (SSM Agent) must be installed on the machine, and Systems Manager must have permission to perform actions on the machine.

For EC2 instances, this permission can be provided at the account level using an AWS Identity and Access Management (IAM) role, or at the instance level using an instance profile. For more information, see [Configure instance permissions required for Systems Manager](#).

For non-EC2 machines, this permission is provided using an IAM service role. For more information, see [Create the IAM service role required for Systems Manager in hybrid and multicloud environments](#).

### Before you begin

In order to use the **Diagnose and remediate** feature to detect unmanaged EC2 instances, you must first onboard your organization or account to the new Systems Manager experience. During this process, you must choose the option to create IAM roles and managed policies required for these operations. For more information, see [Setting up Systems Manager unified console for an organization](#).

Use the following topics to help you identify and fix certain common types of failed deployments, drifted configurations, and unmanaged EC2 instances.

## Topics

- [Diagnosing and remediating failed deployments](#)
- [Diagnosing and remediating drifted configurations](#)
- [Diagnosing and remediating unmanaged Amazon EC2 instances in Systems Manager](#)
- [Remediation impact types of runbook actions](#)
- [Viewing execution progress and history for remediations in Systems Manager](#)

## Diagnosing and remediating failed deployments

Systems Manager can diagnose and then help you remediate the following types of failed deployments:

- Core setup for organization member accounts
- Core setup for delegated administrator account
- Core setup for your account

Use the following procedure to attempt to remediate these types of issues.

### To diagnose and remediate failed deployments

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Diagnose and remediate**.
3. Choose the **Deployment issues** tab.
4. In the **Failed deployments** section, review the list of findings for failed deployments.
5. In the **Setup step** column, choose the name of a finding to review additional details about the issue. For example: **Core setup for organization member accounts**.
6. In the detail page for that failed deployment, you can view a list of accounts and how many Regions in each have experienced deployment failures.
7. Select an account ID to view information about the reason for failures in that account.

8. In the **Failed Regions** area, examine the information provided for **Status reason**. This information can indicate a reason for the failed deployment, which might provide insight into configuration changes that need to be made.
9. If you want to retry the deployment without making configuration changes, choose **Redeploy**.

## Diagnosing and remediating drifted configurations

Systems Manager can diagnose and then help you remediate the following types of drifted configurations:

- Core setup for organization member accounts
- Core setup for delegated administrator account
- Core setup for your account

Use the following procedure to attempt to remediate these types of drifted configurations.

### To diagnose and remediate drifted configurations

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Diagnose and remediate**.
3. Choose the **Deployment issues** tab.
4. In the **Drifted deployments** section, review the list of finding for failed deployments.

-or-

To run a new diagnosis, choose **Detect drift**.

5. In the **Setup step** column, choose the name of a finding to review additional details about the issue. For example: **Core setup for organization member accounts**.
6. In the detail page for that failed deployment, you can view a list of accounts and how many Regions in each have experienced configuration drifts.
7. Select an account ID to view information about the reason for configuration drifts in that account.
8. In the **Drifted resources** area, the **Resource** column reports names of resources that have experienced drift. The **Drift type** column reports whether the resource was modified or deleted..

9. To redeploy the intended configuration, choose **Redeploy**.

## Diagnosing and remediating unmanaged Amazon EC2 instances in Systems Manager

To help you manage your Amazon Elastic Compute Cloud (Amazon EC2) instances with Systems Manager, you can use the unified Systems Manager console experience to do the following:

1. Run a manual or scheduled diagnosis process to identify which EC2 instances in your account or organization aren't currently managed by Systems Manager.
2. Identify network or other issues that are preventing Systems Manager from taking over management of the instances.
3. Run an Automation execution to automatically remediate the problem, or access information to help you manually address the issue.

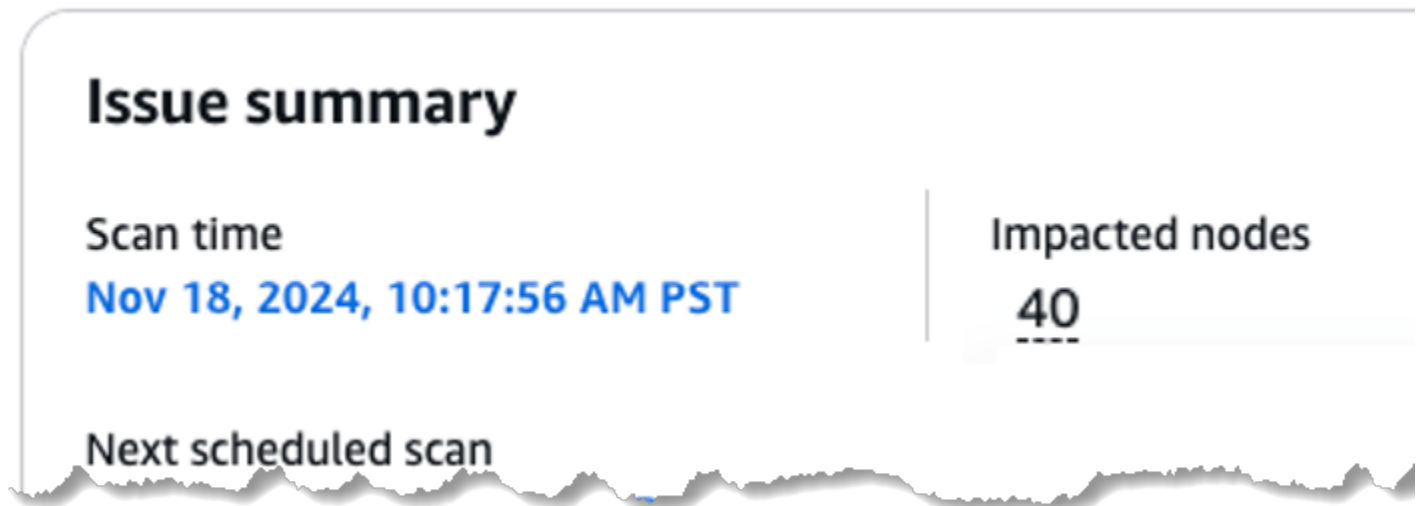

Use the information in the following topics to help you diagnose and remediate issues that are preventing Systems Manager from managing your EC2 instances.

### How Systems Manager counts impacted nodes for the 'Unmanaged EC2 instance issues' list

The number of nodes reported as unmanaged on the **Unmanaged EC2 instances issues** tab represents to the total number of instances with any of the follow status values at the diagnosis scan time:

- Running
- Stopped
- Stopping

This number is reported as **Impacted nodes** in the **Issue summary** area. In the following image, this number of impacted nodes not currently managed by Systems Manager is 40.

Unlike the report of unmanaged EC2 instances on the **Review node insights** page, this count of EC2 instances is not dynamic. It represents findings made during the last reported diagnostic scan, shown as the **Scan time** value. We therefore recommend running a diagnostic scan for unmanaged EC2 instances on a regular schedule to keep this reported number of impacted nodes up to date.

## Topics

- [Categories of diagnosable unmanaged EC2 instance issues](#)
- [Running a diagnosis and optional remediation for unmanaged EC2 instances](#)
- [Scheduling a recurring scan for unmanaged EC2 instances](#)

## Categories of diagnosable unmanaged EC2 instance issues

This topic lists the major categories of EC2 management issues, and the specific issues in each category, that Systems Manager can help you diagnose and remediate. Note that for some of the issues, Systems Manager can identify the issue, but not provide automatic remediation. In those cases, the Systems Manager console directs you to information to help you manually resolve an issue.

The diagnosis process examines each group of EC2 instances at once according to the virtual private cloud (VPC) they belong to.

## Issue types

- [Problem category: Security group configuration and HTTPS communications](#)
- [Problem category: DNS or DNS host name configuration](#)

- [Problem category: VPC endpoint configuration](#)

### Problem category: Security group configuration and HTTPS communications

A diagnosis operation might find that SSM Agent isn't able to communicate with the Systems Manager service over HTTPS. In those cases, you can choose to execute an Automation runbook that attempts to update security groups that are attached to the instances.

#### Note

Occasionally, Systems Manager might not be able to automatically remediate these issues, but you can manually edit the affected security groups.

### Supported issue types

- **Instance security group:** Outbound traffic is not allowed on port 443
- **ssm VPC endpoint's security group:** Inbound traffic is not allowed on port 443
- **ssmmessages VPC endpoint's security group:** Inbound traffic not allowed on port 443
- **ec2messages VPC endpoint's security group:** Inbound traffic not allowed on port 443

For more information, see [Verify ingress rules on endpoint security groups](#) in the topic [Troubleshooting SSM Agent](#).

### Problem category: DNS or DNS host name configuration

A diagnosis operation might find that Domain Name System (DNS) or DNS host names aren't properly configured for the VPC. In those cases, you can choose to execute an Automation runbook that attempts to enable the `enableDnsSupport` and `enableDnsHostnames` attributes of the affected VPC.

### Supported issue types

- DNS support is disabled in a VPC.
- A DNS hostname is disabled in a VPC.

For more information, see [Verify your VPC DNS-related attributes](#) in the topic [Troubleshooting SSM Agent](#).

## Problem category: VPC endpoint configuration

A diagnosis operation might find that VPC endpoints aren't properly configured for the VPC.

If VPC endpoints required by SSM Agent don't exist, Systems Manager attempts to execute an Automation runbook to create the VPC endpoints and associates them with one subnet in each relevant regional availability zone (AZ). If VPC the required endpoints exist but aren't associated with a subnet in which the issue is found, the runbook associates the VPC endpoints to the affected subnet.

### Note

Systems Manager doesn't support remediating all misconfigured VPC endpoint issues. In those cases, Systems Manager directs you to manual remedy instructions instead of running an Automation runbook.

## Supported issue types

- No `ssm.region.amazonaws.com` endpoint for PrivateLink was found.
- No `ssmmessages.region.amazonaws.com` endpoint for PrivateLink was found.
- No `ec2messages.region.amazonaws.com` endpoint for PrivateLink was found.

## Diagnosable issue types

Systems Manager can diagnose the following issue types, but currently no runbook is available for remediating their issues. You can edit your configuration manually for these issues.

- An instance's subnet is not attached to an `ssm.region.amazonaws.com` endpoint.
- An instance's subnet is not attached to an `ssmmessages.region.amazonaws.com` endpoint.
- An instance's subnet not attached to an `ec2messages.region.amazonaws.com` endpoint.

For more information, see [Verify your VPC configuration](#) in the topic [Troubleshooting SSM Agent](#).

## Running a diagnosis and optional remediation for unmanaged EC2 instances

Use the following procedure to diagnose the network-related and VPC-related issues that might be preventing Systems Manager from managing your EC2 instances.

The diagnosis operation can detect and group together issues of the following types:

- **Network configurations issues** – Types of networking issues that might be preventing EC2 instances from communicating with the Systems Manager service in the cloud. Remediation operations might be available for these issues. For more information about the network configuration issues, see [Categories of diagnosable unmanaged EC2 instance issues](#).
- **Unidentified issues** – A list of findings for cases where the diagnostic operation was unable to determine why EC2 instances are not able to communicate with the Systems Manager service in the cloud.

### To run a diagnosis and remediation for unmanaged EC2 instances

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Diagnose and remediate**.
3. Choose the **Unmanaged EC2 instances issue** tab.
4. In the **Issue summary** section, choose **Run new diagnosis**.

-or-

If this is your first time to diagnose unmanaged EC2 issues, in the **Diagnose unmanaged EC2 instances** section, choose **Execute**.

#### Tip

While the diagnosis is running, choose **View progress** or **View executions** to monitor the current state of the execution. For more information, see [Viewing execution progress and history for remediations in Systems Manager](#).

5. After the diagnosis completes, do the following:
  - For any issues reported in the **Unidentified issues** section, choose the **Learn more** link for information about resolving the problem.
  - For issues reported in the **Network configurations issues** section, continue with the next step.
6. In the list of finding types, in the **Recommendations** column, for a particular issue, choose the link, such as **2 recommendations**.

7. In the **Recommendations** pane that opens, choose from the available mitigations:
  - **Learn more** – Open a topic with information about how to resolve an issue manually.
  - **View runbook** – Open a pane with information about the Automation runbook you can execute to resolve the issue with your EC2 instances, as well as options for generating a *preview* of the actions that runbook would take. Continue with the next step.
8. In the runbook pane, do the following:
  - a. For **Document description**, review the content, which provides an overview of the actions the runbook can take to remediate your unmanaged EC2 instance issues. Choose **View steps** to preview the individual actions the runbook would take.
  - b. For **Targets**, do the following:
    - If you are managing remediations for an organization, for **Accounts**, specify whether this runbook would target all accounts, or only a subset of accounts you choose.
    - For **Regions**, specify whether this runbook would target all AWS Regions in your account or organization, or only a subset of Regions you choose.
  - c. For **Runbook preview**, carefully review the information. This information explains what the scope and impact would be if you choose to execute the runbook.

 **Note**

Choosing to execute the runbook would incur charges. Review the preview information carefully before deciding whether to proceed.

The **Runbook preview** content provides the following information:

- How many Regions the runbook operation would occur in.
- (Organizations only) How many organizational units (OUs) the operation would run in.
- The types of actions that would be taken, and how many of each.

Action types include the following:

- **Mutating:** The runbook step would make changes to the targets through actions that create, modify, or delete resources.

- **Non-mutating:** The runbook step would retrieve data about resources but not make changes to them. This category generally includes `Describe*`, `List*`, `Get*`, and similar read-only API actions.
  - **Undetermined:** An undetermined step invokes executions performed by another orchestration service like AWS Lambda, AWS Step Functions, or AWS Systems Manager Run Command. An undetermined step might also call a third-party API. Systems Manager Automation doesn't know the outcome of the orchestration processes or third-party API executions, so the results of the steps are undetermined.
- d. At this point, you can choose one of the following actions:
- Stop and do not execute the runbook.
  - Choose **Execute** to run the runbook with the options you have already selected.

If you choose to run the operation, choose **View progress** or **View executions** to monitor the current state of the execution. For more information, see [Viewing execution progress and history for remediations in Systems Manager](#).

## Scheduling a recurring scan for unmanaged EC2 instances

You can run an on-demand scan for Amazon EC2 instances in your account or organization that Systems Manager isn't able to manage due to various configuration issues. You can also schedule this scan to occur automatically on a regular schedule.

### To schedule a recurring scan for unmanaged EC2 instances

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Diagnose and remediate**.
3. Choose the **Unmanaged EC2 instances issue** tab.
4. In the **Diagnose unmanaged EC2 instances** section, turn on **Schedule recurring diagnosis**.
5. For **Diagnostic frequency**, select whether to run the diagnosis once a day or once a week.
6. (Optional) For **Start time**, enter a time, in 24-hour format, for the diagnosis to begin. For example, for 8:15 PM, enter **20:15**.

The time you enter is for your current local time zone.

If you don't specify a time, the diagnostic scan runs immediately. Systems Manager also schedules the scan to run in the future at the current time. If you specify a time, Systems Manager waits to run the diagnostic scan at the specified time.

7. Choose **Execute**. The diagnosis runs immediately, but will also run on the schedule you have specified.

## Remediation impact types of runbook actions

Systems Manager can run diagnosis operations that discover certain types of failed deployments and drifted configurations, as well as certain types of configuration issues that are preventing Systems Manager from managing EC2 instances. The results of the diagnosis might include recommendations for Automation runbooks that you can execute to attempt to remedy a problem. For more information about these diagnosis operations, see the following topics:

- [Diagnosing and remediating failed deployments](#)
- [Diagnosing and remediating drifted configurations](#)
- [Diagnosing and remediating unmanaged Amazon EC2 instances in Systems Manager](#)

When Systems Manager identifies an issue that might be fixed by running an Automation runbook on the affected resources, it provides you with an *execution preview*. The execution preview provides information about the *types* of changes the runbook execution would make to your targets. This information includes how many of each of three types of changes the diagnosis identified.

These change types are as follows:

- **Mutating:** A runbook step would make changes to the targets through actions that create, modify, or delete resources.
- **Non-Mutating:** A runbook step would retrieve data about resources but not make changes to them. This category generally includes `Describe*`, `List*`, `Get*`, and similar read-only API actions.
- **Undetermined:** An undetermined step invokes executions performed by another orchestration service like AWS Lambda, AWS Step Functions, or Run Command, a capability of AWS Systems Manager. An undetermined step might also call a third-party API or run a Python or PowerShell script. Systems Manager Automation can't detect what the outcome would be of the

orchestration processes or third-party API executions, and therefore can't evaluate them. The results of those steps would have to be manually reviewed to determine their impact.

See the following table for information about the impact type of supported Automation actions.

## Impact types of supported remediation actions

The table presents the impact type—Mutating, Non-mutating, and Undetermined—of various actions that can be included in a remediation runbook.

| Action <sup>1</sup>           | Impact type  |
|-------------------------------|--------------|
| aws:approve                   | Non-mutating |
| aws:assertAwsResourceProperty | Non-mutating |
| aws:branch                    | Non-mutating |
| aws:changeInstanceState       | Mutating     |
| aws:copyImage                 | Mutating     |
| aws:createImage               | Mutating     |
| aws:createStack               | Mutating     |
| aws:createTags                | Mutating     |
| aws:deleteImage               | Mutating     |
| aws:deleteStack               | Mutating     |
| aws:executeAutomation         | Undetermined |
| aws:executeAwsApi             | Undetermined |
| aws:executeScript             | Undetermined |
| aws:executeStateMachine       | Undetermined |
| aws:invokeLambdaFunction      | Undetermined |

| Action <sup>1</sup>            | Impact type                                 |
|--------------------------------|---|
| aws:invokeWebhook              | Undetermined                                |
| aws:loop                       | Varies. Depends on the actions in the loop. |
| aws:pause                      | Non-mutating                                |
| aws:runCommand                 | Undetermined                                |
| aws:runInstances               | Mutating                                    |
| aws:sleep                      | Non-mutating                                |
| aws:updateVariable             | Mutating                                    |
| aws:waitForAwsResourceProperty | Non-mutating                                |

<sup>1</sup> For more information about Automation actions, see [Systems Manager Automation actions reference](#).

## Viewing execution progress and history for remediations in Systems Manager

You can view a list of all in-progress and completed remediation operations made using the **Diagnose and remediate** feature in Systems Manager.

Data in the execution history list reports the following types of information:

- The type of execution, Diagnosis or Remediation.
- The execution status, such as Success or Failed.
- The times that the execution started and ended.

### To view execution progress and history for remediations

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Diagnose and remediate**.

### 3. Choose **View executions**.

#### **Tip**

When an execution is running, you can also choose **View progress** to open the **Execution history** page.

### 4. (Optional) In the search

box, enter a phrase to help narrow down the execution list, such as **EC2** or **VPC**.

### 5. (Optional) To view additional details about an execution, in the **Execution name** column, choose an operation name, such as **AWS-DiagnoseUnmanagedEC2NetworkIssues**.

In the details pane, you can review information about all the steps attempted during the operation, and about all the inputs and outputs for the execution.

## Adjusting Systems Manager settings

The options on the **Settings** pages enable and configure features in the Systems Manager unified console. The options displayed depend on the account you are logged into and whether or not you have already set up Systems Manager.

#### **Note**

The options on the **Settings** page don't affect Systems Manager tools (formerly called capabilities).

## Account setup settings

If Systems Manager is enabled, and if you are logged into an account that is not a member of Organizations or if the delegated administrator has not added your Organizations account to Systems Manager, the **Account setup** page shows the option to **Disable Systems Manager**. Disabling Systems Manager means Systems Manager doesn't display the unified console experience. All Systems Manager tools still function.

## Organizational setup settings

On the **Organizational setup** tab, the **Home Region** section displays the AWS Region chosen as the home Region during setup. In multi-account and multi-Region environments that use AWS Organizations, Systems Manager automatically aggregates node data from all accounts and Regions to the home Region. Aggregating data in this way enables you to view node data across accounts and Regions in a single location.

### Note

If you want to change the home Region, you must disable Systems Manager and enable it again. To disable Systems Manager, choose **Disable**.

The **Organizational setup** section displays the AWS organizational units and AWS Regions chosen during setup. To change which organizational units and Regions display node data in Systems Manager, choose **Edit**. For more information about setting up Systems Manager for Organizations, see [Setting up AWS Systems Manager](#).

## Diagnose and remediate settings

The **Diagnose and remediate** settings determine whether or not Systems Manager automatically scans your nodes to ensure they can communicate with Systems Manager. If enabled, the feature runs automatically according to a schedule you define. The feature identifies which nodes can't connect to Systems Manager and why. This feature also provides recommended runbooks for remediating networking issues and other problems preventing nodes from being configured as managed nodes.

### Scheduling a recurring diagnostic scan

Systems Manager can diagnose and help you remediate several types of deployment failures, as well as drifted configurations. Systems Manager can also identify Amazon Elastic Compute Cloud (Amazon EC2) instances in your account or organization that Systems Manager isn't able to treat as a *managed node*. The EC2 instance diagnosis process can identify issues related to misconfigurations for a virtual private cloud (VPC), in a Domain Name Service (DNS) setting, or in an Amazon Elastic Compute Cloud (Amazon EC2) security group.

To simplify the task of identifying nodes that can't connect to Systems Manager, the **Schedule recurring diagnosis** feature enables you to automate a recurring diagnostic scan. The scans help

identify which nodes can't connect to Systems Manager and why. Use the following procedure to enable and configure a recurring diagnostic scan of your nodes.

### To schedule a recurring diagnostic scan

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Settings**, and then choose the **Diagnose and remediate** tab.
3. Turn on the **Schedule recurring diagnosis** option.
4. For **Scanning period**, choose how often you want the scan to run.
5. (Optional) For **Start time**, enter a time, in 24-hour format, for the diagnosis to begin. For example, for 8:15 PM, enter **20:15**.

The time you enter is for your current local time zone.

If you don't specify a time, the diagnostic scan runs immediately. Systems Manager also schedules the scan to run in the future at the current time. If you specify a time, Systems Manager waits to run the diagnostic scan at the specified time.

6. Choose **Save**.
7. After the scan completes, view the details by choosing **Diagnose and remediate** in the left navigation.

For more information about the **Diagnose and remediate** feature, see [Diagnosing and remediating](#).

### Updating S3 bucket encryption

When you onboard Systems Manager, Quick Setup creates an Amazon Simple Storage Service (Amazon S3) bucket in the delegated administrator account for AWS Organizations setups. For single-account setups, the bucket is stored in the account being set up. This bucket is used to store the metadata generated during diagnostic scans.

For more information about setting up the Systems Manager unified experience, see [Setting up AWS Systems Manager](#).

By default, your data in the bucket is encrypted using a AWS Key Management Service (AWS KMS) key that AWS owns and manages for you.

You can choose to use a different AWS KMS key for your bucket encryption. As another alternative, you can use server-side encryption with AWS KMS keys (SSE-KMS) using a customer managed key (CMK). For information, see [Working with Amazon S3 buckets and bucket policies for Systems Manager](#).

### To use a different AWS KMS key for S3 bucket encryption

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Settings**, and then choose the **Diagnose and remediate** tab.
3. In the **Update S3 bucket encryption** area, choose **Edit**.
4. Select the **Customize encryption settings (advanced)** check box.
5. For **Choose an AWS KMS key**, choose or enter the Amazon Resource Name (ARN) of the key.

#### Tip

To create a new key, choose **Create an AWS KMS key**.

6. Choose **Save**.

## Working with Amazon S3 buckets and bucket policies for Systems Manager

During the [onboarding process](#) for AWS Systems Manager, Quick Setup creates an Amazon Simple Storage Service (Amazon S3) bucket in the delegated administrator account for organization setups. For single-account setups, the bucket is stored in the account being set up.

You can use Systems Manager to run diagnostic operations on your fleet to identify cases of failed deployments and drifted configurations. Systems Manager can also detect cases where configuration issues are preventing Systems Manager from managing EC2 instances in your account or organization. The results of these diagnostic operations are stored in this Amazon S3 bucket, which is protected by both an encryption method and an S3 bucket policy. For information about the diagnostic operations that output data to this bucket, see [Diagnosing and remediating](#).

### Changing the bucket encryption method

By default, the S3 bucket uses server-side encryption with Amazon S3 managed keys (SSE-S3).

You can instead use server-side encryption with AWS KMS keys (SSE-KMS) using a customer managed key (CMK) as an alternative to Amazon S3 managed keys, as explained in [Changing to an AWS KMS customer managed key to encrypt S3 resources](#).

## Contents of the bucket policy

The bucket policy prevents member accounts in an organization from discovering one another. Read and write permissions to the bucket are allowed only for the diagnosis and remediation roles created for Systems Manager. The contents of these system-generated policies are presented in [S3 bucket policies for the new Systems Manager experience](#).

### Warning

Modifying the default bucket policy might allow member accounts in an organization to discover one another, or read diagnosis outputs for instances in another account. We recommend using extreme caution if you choose to modify this policy.

## Topics

- [Changing to an AWS KMS customer managed key to encrypt S3 resources](#)
- [S3 bucket policies for the new Systems Manager experience](#)

## Changing to an AWS KMS customer managed key to encrypt S3 resources

During the onboarding process for the new Systems Manager experience, Quick Setup creates an Amazon Simple Storage Service (Amazon S3) bucket in the delegated administrator account. This bucket is used to store the diagnosis output data generated during remediation runbook executions. By default, the bucket uses server-side encryption with Amazon S3 managed keys (SSE-S3).

You can review the content of these policies in [S3 bucket policies for the new Systems Manager experience](#).

However, you can instead use server-side encryption with AWS KMS keys (SSE-KMS) using a customer managed key (CMK) as an alternative to an AWS KMS key.

Complete the following tasks in order to configure Systems Manager to use your CMK.

## Task 1: Add a tag to an existing CMK

AWS Systems Manager uses your CMK only if it is tagged with the following key-value pair:

- Key: `SystemsManagerManaged`
- Value: `true`

Use the following procedure to provide access for encrypting the S3 bucket with your CMK.

### To add a tag to your existing CMK

1. Open the AWS KMS console at <https://console.aws.amazon.com/kms>.
2. In the left navigation, choose **Customer managed keys**.
3. Select the AWS KMS key to use with AWS Systems Manager.
4. Choose the **Tags** tab, and then choose **Edit**.
5. Choose **Add tag**.
6. Do the following:
  - a. For **Tag key**, enter **SystemsManagerManaged**.
  - b. For **Tag value**, enter **true**.
7. Choose **Save**.

## Task 2: Modify an existing CMK key policy

Use the following procedure to update the [KMS key policy](#) of your CMK to allow AWS Systems Manager roles to encrypt the S3 bucket on your behalf.

### To modify an existing CMK key policy

1. Open the AWS KMS console at <https://console.aws.amazon.com/kms>.
2. In the left navigation, choose **Customer managed keys**.
3. Select the AWS KMS key to use with AWS Systems Manager.
4. On the **Key policy** tab, choose **Edit**.
5. Add the following JSON statement to the Statement field, and replace the *placeholder values* with your own information.

Ensure that you add all AWS account IDs that are onboarded in your organization to AWS Systems Manager in the `Principal` field.

To locate the correct bucket name in the Amazon S3 console, in the delegated administrator account, locate the bucket in the format `do-not-delete-ssm-operational-account-id-home-region-disambiguator`.

```
{
  "Sid": "EncryptionForSystemsManagerS3Bucket",
  "Effect": "Allow",
  "Principal": {
    "AWS": [
      "account-id-1",
      "account-id-2",
      ...
    ]
  },
  "Action": ["kms:Decrypt", "kms:GenerateDataKey"],
  "Resource": "*",
  "Condition": {
    "StringEquals": {
      "kms:EncryptionContext:aws:s3:arn": "arn:aws:s3:::bucket-name"
    },
    "StringLike": {
      "kms:ViaService": "s3.*.amazonaws.com"
    },
    "ArnLike": {
      "aws:PrincipalArn": "arn:aws:iam::*:role/AWS-SSM-*"
    }
  }
}
```

### Tip

Alternatively, you can update the CMK key policy using the [aws:PrincipalOrgID](#) condition key to grant AWS Systems Manager access to your CMK.

### Task 3: Specify the CMK in Systems Manager settings

After completing the previous two tasks, use the following procedure to change the S3 bucket encryption. This change ensures that the associated Quick Setup configuration process can add permissions for Systems Manager to accept your CMK.

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Settings**.
3. On the **Diagnose and remediate** tab, in the **Update S3 bucket encryption** section, choose **Edit**.
4. Select the **Customize encryption settings (advanced)** check box.
5. In the search  box, choose the ID of an existing key, or paste the ARN of an existing key.
6. Choose **Save**.

### S3 bucket policies for the new Systems Manager experience

This topic includes the Amazon S3 bucket policies created by Systems Manager when you onboard an organization or single account to the new Systems Manager experience.

#### **Warning**

Modifying the default bucket policy might allow member accounts in an organization to discover one another, or read diagnosis outputs for instances in another account. We recommend using extreme caution if you choose to modify this policy.

#### Amazon S3 bucket policy for an organization

The diagnosis bucket is created with the following default bucket policy when onboarding an organization to Systems Manager.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
```

```

    "Sid": "DenyHTTPRequests",
    "Effect": "Deny",
    "Principal": "*",
    "Action": "s3:*",
    "Resource": [
        "arn:aws:s3:::",
        "arn:aws:s3:::bucket-name/*"
    ],
    "Condition": {
        "Bool": {
            "aws:SecureTransport": "false"
        }
    }
},
{
    "Sid": "DenyNonSigV4Requests",
    "Effect": "Deny",
    "Principal": "*",
    "Action": "s3:*",
    "Resource": [
        "arn:aws:s3:::bucket-name",
        "arn:aws:s3:::bucket-name/*"
    ],
    "Condition": {
        "StringNotEquals": {
            "s3:SignatureVersion": "AWS4-HMAC-SHA256"
        }
    }
},
{
    "Sid": "AllowAccessLog",
    "Effect": "Allow",
    "Principal": {
        "Service": "logging.s3.amazonaws.com"
    },
    "Action": "s3:PutObject",
    "Resource": "arn:aws:s3:::bucket-name/access-logs/*",
    "Condition": {
        "StringEquals": {
            "aws:SourceAccount": "operational-account-id"
        },
        "ArnLike": {
            "aws:SourceArn": "arn:aws:s3:::bucket-name"
        }
    }
}

```

```

    }
  },
  {
    "Sid": "AllowCrossAccountRead",
    "Effect": "Allow",
    "Principal": "*",
    "Action": "s3:GetObject",
    "Resource": "arn:aws:s3:::bucket-name/actions/*/${aws:PrincipalAccount}/*",
    "Condition": {
      "StringEquals": {
        "aws:PrincipalOrgID": "organization-id"
      }
    }
  },
  {
    "Sid": "AllowCrossAccountWrite",
    "Effect": "Allow",
    "Principal": "*",
    "Action": [
      "s3:PutObject",
      "s3:DeleteObject"
    ],
    "Resource": "arn:aws:s3:::bucket-name/actions/*/${aws:PrincipalAccount}/*",
    "Condition": {
      "StringEquals": {
        "aws:PrincipalOrgID": "organization-id"
      },
      "ArnLike": {
        "aws:PrincipalArn": [
          "arn:aws:iam::*:role/AWS-SSM-
DiagnosisExecutionRole-operational-account-id-home-region",
          "arn:aws:iam::*:role/AWS-SSM-DiagnosisAdminRole-operational-
account-id-home-region",
          "arn:aws:iam::*:role/AWS-SSM-
RemediationExecutionRole-operational-account-id-home-region",
          "arn:aws:iam::*:role/AWS-SSM-RemediationAdminRole-operational-
account-id-home-region"
        ]
      }
    }
  },
  {
    "Sid": "AllowCrossAccountListUnderAccountOwnPrefix",
    "Effect": "Allow",

```

```

    "Principal": "*",
    "Action": "s3:ListBucket",
    "Resource": "arn:aws:s3:::bucket-name",
    "Condition": {
      "StringEquals": {
        "aws:PrincipalOrgID": "organization-id"
      },
      "StringLike": {
        "s3:prefix": "*/${aws:PrincipalAccount}/*"
      }
    }
  },
  {
    "Sid": "AllowCrossAccountGetConfigWithinOrganization",
    "Effect": "Allow",
    "Principal": "*",
    "Action": "s3:GetEncryptionConfiguration",
    "Resource": "arn:aws:s3:::bucket-name",
    "Condition": {
      "StringEquals": {
        "aws:PrincipalOrgID": "organization-id"
      }
    }
  }
]
}

```

## Amazon S3 bucket policy for a single account

The diagnosis bucket is created with the following default bucket policy when onboarding a single account to Systems Manager.

```

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "DenyHTTPRequests",
      "Effect": "Deny",
      "Principal": "*",
      "Action": "s3:*",
      "Resource": [
        "arn:aws:s3:::bucket-name",
        "arn:aws:s3:::bucket-name/*"
      ]
    }
  ]
}

```

```
    ],
    "Condition": {
      "Bool": {
        "aws:SecureTransport": "false"
      }
    }
  },
  {
    "Sid": "DenyNonSigV4Requests",
    "Effect": "Deny",
    "Principal": "*",
    "Action": "s3:*",
    "Resource": [
      "arn:aws:s3:::bucket-name",
      "arn:aws:s3:::bucket-name/*"
    ],
    "Condition": {
      "StringNotEquals": {
        "s3:SignatureVersion": "AWS4-HMAC-SHA256"
      }
    }
  }
]
}
```

# AWS Systems Manager tools

Systems Manager groups tools into the following categories. The following documentation describes the various tools of AWS Systems Manager and how to set up and use these tools. Choose the tabs under each category to learn more about each tool.

## Application management

### Application Manager

[Application Manager](#) helps DevOps engineers investigate and remediate issues with their AWS resources in the context of their applications and clusters. In Application Manager, an *application* is a logical group of AWS resources that you want to operate as a unit. This logical group can represent different versions of an application, ownership boundaries for operators, or developer environments, to name a few. Application Manager support for container clusters includes both Amazon Elastic Kubernetes Service (Amazon EKS) and Amazon Elastic Container Service (Amazon ECS) clusters. Application Manager aggregates operations information from multiple AWS services and Systems Manager capabilities to a single AWS Management Console.

### AppConfig

[AppConfig](#) helps you create, manage, and deploy application configurations and feature flags. AppConfig supports controlled deployments to applications of any size. You can use AppConfig with applications hosted on Amazon EC2 instances, AWS Lambda containers, mobile applications, or edge devices. To prevent errors when deploying application configurations, AppConfig includes validators. A validator provides a syntactic or semantic check to verify that the configuration you want to deploy works as intended. During a configuration deployment, AppConfig monitors the application to verify that the deployment is successful. If the system encounters an error or if the deployment invokes an alarm, AppConfig rolls back the change to minimize impact for your application users.

### Parameter Store

[Parameter Store](#) provides secure, hierarchical storage for configuration data and secrets management. You can store data such as passwords, database strings, Amazon Elastic Compute Cloud (Amazon EC2) instance IDs and Amazon Machine Image (AMI) IDs, and license codes as parameter values. You can store values as plain text or encrypted data. You can then reference values by using the unique name you specified when you created the parameter.

# Change management

## Change Manager

[Change Manager](#) is an enterprise change management framework for requesting, approving, implementing, and reporting on operational changes to your application configuration and infrastructure. From a single *delegated administrator account*, if you use AWS Organizations, you can manage changes across multiple AWS accounts in multiple AWS Regions. Alternatively, using a *local account*, you can manage changes for a single AWS account. Use Change Manager for managing changes to both AWS resources and on-premises resources.

## Automation

Use [Automation](#) to automate common maintenance and deployment tasks. You can use Automation to create and update Amazon Machine Images (AMIs), apply driver and agent updates, reset passwords on Windows Server instance, reset SSH keys on Linux instances, and apply OS patches or application updates.

## Change Calendar

[Change Calendar](#) helps you set up date and time ranges when actions you specify (for example, in [Systems Manager Automation](#) runbooks) can or can't be performed in your AWS account. In Change Calendar, these ranges are called *events*. When you create a Change Calendar entry, you're creating a [Systems Manager document](#) of the type `ChangeCalendar`. In Change Calendar, the document stores [iCalendar 2.0](#) data in plaintext format. Events that you add to the Change Calendar entry become part of the document. You can add events manually in the Change Calendar interface or import events from a supported third-party calendar using an `.ics` file.

## Maintenance Windows

Use [Maintenance Windows](#) to set up recurring schedules for managed instances to run administrative tasks such as installing patches and updates without interrupting business-critical operations.

# Node management

A *managed node* is any machine configured for use with Systems Manager in [hybrid and multicloud](#) environments.

## Compliance

Use [Compliance](#) to scan your fleet of managed nodes for patch compliance and configuration inconsistencies. You can collect and aggregate data from multiple AWS accounts and AWS Regions, and then drill down into specific resources that aren't compliant. By default, Compliance displays compliance data about Patch Manager patching and State Manager associations. You can also customize the service and create your own compliance types based on your IT or business requirements.

## Fleet Manager

[Fleet Manager](#) is a unified user interface (UI) experience that helps you remotely manage your nodes. With Fleet Manager, you can view the health and performance status of your entire fleet from one console. You can also gather data from individual devices and instances to perform common troubleshooting and management tasks from the console. This includes viewing directory and file contents, Windows registry management, operating system user management, and more.

## Inventory

[Inventory](#) automates the process of collecting software inventory from your managed nodes. You can use Inventory to gather metadata about applications, files, components, patches, and more.

## Session Manager

Use [Session Manager](#) to manage your edge devices and Amazon Elastic Compute Cloud (Amazon EC2) instances through an interactive one-click browser-based shell or through the AWS CLI. Session Manager provides secure and auditable edge device and instance management without needing to open inbound ports, maintain bastion hosts, or manage SSH keys. Session Manager also allows you to comply with corporate policies that require controlled access to edge devices and instances, strict security practices, and fully auditable logs with edge device and instance access details, while still providing end users with simple one-click cross-platform access to your edge devices and EC2 instances. To use Session Manager, you must enable the advanced-instances tier. For more information, see [Turning on the advanced-instances tier](#).

## Run Command

Use [Run Command](#) to remotely and securely manage the configuration of your managed nodes at scale. Use Run Command to perform on-demand changes such as updating applications or

running Linux shell scripts and Windows PowerShell commands on a target set of dozens or hundreds of managed nodes.

## State Manager

Use [State Manager](#) to automate the process of keeping your managed nodes in a defined state. You can use State Manager to guarantee that your managed nodes are bootstrapped with specific software at startup, joined to a Windows domain (Windows Server nodes only), or patched with specific software updates.

## Patch Manager

Use [Patch Manager](#) to automate the process of patching your managed nodes with both security related and other types of updates. You can use Patch Manager to apply patches for both operating systems and applications. (On Windows Server, application support is limited to updates for applications released by Microsoft.)

This capability allows you to scan managed nodes for missing patches and apply missing patches individually or to large groups of managed nodes by using tags. Patch Manager uses *patch baselines*, which can include rules for auto-approving patches within days of their release, and a list of approved and rejected patches. You can install security patches on a regular basis by scheduling patching to run as a Systems Manager maintenance window task, or you can patch your managed nodes on demand at any time.

For Linux operating systems, you can define the repositories that should be used for patching operations as part of your patch baseline. This allows you to ensure that updates are installed only from trusted repositories regardless of what repositories are configured on the managed node. For Linux, you also have the ability to update any package on the managed node, not just those that are classified as operating system security updates. You can also generate patch reports that are sent to an S3 bucket of your choice. For a single managed node, reports include details of all patches for the machine. For a report on all managed nodes, only a summary of how many patches are missing is provided.

## Distributor

Use [Distributor](#) to create and deploy packages to managed nodes. With Distributor, you can package your own software—or find AWS-provided agent software packages, such as **AmazonCloudWatchAgent**—to install on Systems Manager managed nodes. After you install a package for the first time, you can use Distributor to uninstall and reinstall a new package version, or perform an in-place update that adds new or changed files. Distributor publishes resources, such as software packages, to Systems Manager managed nodes.

## Hybrid Activations

To set up non-EC2 machines in your hybrid and multicloud environment as managed nodes, create a [hybrid activation](#). After you complete the activation, you receive an activation code and ID. This code and ID combination functions like an Amazon Elastic Compute Cloud (Amazon EC2) access ID and secret key to provide secure access to the Systems Manager service from your managed instances.

You can also create an activation for edge devices if you want to manage them by using Systems Manager.

# Operations management

## Incident Manager

[Incident Manager](#) is an incident management console that helps users mitigate and recover from incidents affecting their AWS hosted applications.

Incident Manager increases incident resolution by notifying responders of impact, highlighting relevant troubleshooting data, and providing collaboration tools to get services back up and running. Incident Manager also automates response plans and allows responder team escalation.

## Explorer

[Explorer](#) is a customizable operations dashboard that reports information about your AWS resources. Explorer displays an aggregated view of operations data (OpsData) for your AWS accounts and across AWS Regions. In Explorer, OpsData includes metadata about your Amazon EC2 instances, patch compliance details, and operational work items (OpsItems). Explorer provides context about how OpsItems are distributed across your business units or applications, how they trend over time, and how they vary by category. You can group and filter information in Explorer to focus on items that are relevant to you and that require action. When you identify high priority issues, you can use OpsCenter, a capability of Systems Manager, to run Automation runbooks and resolve those issues.

## OpsCenter

[OpsCenter](#) provides a central location where operations engineers and IT professionals can view, investigate, and resolve operational work items (OpsItems) related to AWS resources. OpsCenter is designed to reduce mean time to resolution for issues impacting AWS resources.

This Systems Manager capability aggregates and standardizes OpsItems across services while providing contextual investigation data about each OpsItem, related OpsItems, and related resources. OpsCenter also provides Systems Manager Automation runbooks that you can use to resolve issues. You can specify searchable, custom data for each OpsItem. You can also view automatically generated summary reports about OpsItems by status and source.

## CloudWatch Dashboards

[Amazon CloudWatch Dashboards](#) are customizable pages in the CloudWatch console that you can use to monitor your resources in a single view, even those resources that are spread across different regions. You can use CloudWatch dashboards to create customized views of the metrics and alarms for your AWS resources.

## Quick Setup

Use [Quick Setup](#) to configure frequently used AWS services and features with recommended best practices. You can use Quick Setup in an individual AWS account or across multiple AWS accounts and AWS Regions by integrating with AWS Organizations. Quick Setup simplifies setting up services, including Systems Manager, by automating common or recommended tasks. These tasks include, for example, creating required AWS Identity and Access Management (IAM) instance profile roles and setting up operational best practices, such as periodic patch scans and inventory collection.

## Shared resources

### Documents

A [Systems Manager document](#) (SSM document) defines the actions that Systems Manager performs. SSM document types include *Command* documents, which are used by State Manager and Run Command, and Automation runbooks, which are used by Systems Manager Automation. Systems Manager includes dozens of pre-configured documents that you can use by specifying parameters at runtime. Documents can be expressed in JSON or YAML, and include steps and parameters that you specify.

## AWS Systems Manager Quick Setup

Use Quick Setup, a capability of AWS Systems Manager, to quickly configure frequently used Amazon Web Services services and features with recommended best practices. Quick

Setup simplifies setting up services, including Systems Manager, by automating common or recommended tasks. These tasks include, for example, creating required AWS Identity and Access Management (IAM) instance profile roles and setting up operational best practices, such as periodic patch scans and inventory collection. There is no cost to use Quick Setup. However, costs can be incurred based on the type of services you set up and the usage limits with no fees for the services used to set up your service. To get started with Quick Setup, open the [Systems Manager console](#). In the navigation pane, choose **Quick Setup**.

 **Note**

If you were directed to Quick Setup to help you configure your instances to be managed by Systems Manager, complete the procedure in [Set up Amazon EC2 host management using Quick Setup](#).

## What are the benefits of Quick Setup?

Benefits of Quick Setup include the following:

- **Simplify service and feature configuration**

Quick Setup walks you through configuring operational best practices and automatically deploys those configurations. The Quick Setup dashboard displays a real-time view of your configuration deployment status.

- **Deploy configurations automatically across multiple accounts**

You can use Quick Setup in an individual AWS account or across multiple AWS accounts and AWS Regions by integrating with AWS Organizations. Using Quick Setup across multiple accounts helps to ensure that your organization maintains consistent configurations.

- **Eliminate configuration drift**

Configuration drift occurs whenever a user makes any change to a service or feature that conflicts with the selections made through Quick Setup. Quick Setup periodically checks for configuration drift and attempts to remediate it.

## Who should use Quick Setup?

Quick Setup is most beneficial for customers who already have some experience with the services and features they're setting up, and want to simplify their setup process. If you're unfamiliar with the AWS service you're configuring with Quick Setup, we recommend that you learn more about the service. Review the content in the relevant User Guide before you create a configuration with Quick Setup.

## Availability of Quick Setup in AWS Regions

In the following AWS Regions, you can use all Quick Setup configuration types for an entire organization, as configured in AWS Organizations, or for only the organizational accounts and Regions you choose. You can also use Quick Setup with just a single account in these Regions.

- US East (Ohio)
- US East (N. Virginia)
- US West (N. California)
- US West (Oregon)
- Asia Pacific (Mumbai)
- Asia Pacific (Seoul)
- Asia Pacific (Singapore)
- Asia Pacific (Sydney)
- Asia Pacific (Tokyo)
- Canada (Central)
- Europe (Frankfurt)
- Europe (Stockholm)
- Europe (Ireland)
- Europe (London)
- Europe (Paris)
- South America (São Paulo)

In the following Regions, only the [Host Management](#) configuration type is available for individual accounts:

- Europe (Milan)

- Asia Pacific (Hong Kong)
- Middle East (Bahrain)
- China (Beijing)
- China (Ningxia)
- AWS GovCloud (US-East)
- AWS GovCloud (US-West)

For a list of all supported Regions for Systems Manager, see the **Region** column in [Systems Manager service endpoints](#) in the *Amazon Web Services General Reference*.

## Getting started with Quick Setup

Use the information in this topic to help you prepare to use Quick Setup.

## IAM roles and permissions for Quick Setup onboarding

Quick Setup launched a new console experience and a new API. Now you can interact with this API using the console, AWS CLI, AWS CloudFormation, and SDKs. If you opt in to the new experience, your existing configurations are recreated using the new API. Depending on the number of existing configurations in your account, this process can take several minutes.

To use the new Quick Setup console, you must have permissions for the following actions:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ssm-quicksetup:*",
        "cloudformation:DescribeStackSetOperation",
        "cloudformation:ListStacks",
        "cloudformation:DescribeStacks",
        "cloudformation:DescribeStackResources",

```

```
"cloudformation:ListStackSetOperations",
"cloudformation:ListStackInstances",
"cloudformation:DescribeStackSet",
"cloudformation:ListStackSets",
"cloudformation:DescribeStackInstance",
"cloudformation:DescribeOrganizationsAccess",
"cloudformation:ActivateOrganizationsAccess",
"cloudformation:GetTemplate",
"cloudformation:ListStackSetOperationResults",

        "iam:CreateServiceLinkedRole"
    ],
    "Condition": {
        "StringEquals": {
            "iam:AWSServiceName": [
                "accountdiscovery.ssm.amazonaws.com",
                "ssm.amazonaws.com",
                "ssm-quicksetup.amazonaws.com",
                "stacksets.cloudformation.amazonaws.com"
            ]
        }
    }
}

```

```
    }
  },
  "Resource": "*"
},
{
  "Effect": "Allow",
  "Action": [
    "iam:CreateServiceLinkedRole"
  ],
  "Resource": "arn:aws:iam::*:role/aws-service-role/
stacksets.cloudformation.amazonaws.com/
AWSServiceRoleForCloudFormationStackSetsOrgAdmin"
}
]
```

To restrict users to read-only permissions, only allow `ssm-quicksetup:List*` and `ssm-quicksetup:Get*` operations for the Quick Setup API.

During onboarding, Quick Setup creates the following AWS Identity and Access Management (IAM) roles on your behalf:

- `AWS-QuickSetup-LocalExecutionRole` – Grants AWS CloudFormation permissions to use any template, excluding the patch policy template, and create the necessary resources.
- `AWS-QuickSetup-LocalAdministrationRole` – Grants permissions to AWS CloudFormation to assume `AWS-QuickSetup-LocalExecutionRole`.
- `AWS-QuickSetup-PatchPolicy-LocalExecutionRole` – Grants permissions to AWS CloudFormation to use the patch policy template, and create the necessary resources.
- `AWS-QuickSetup-PatchPolicy-LocalAdministrationRole` – Grants permissions to AWS CloudFormation to assume `AWS-QuickSetup-PatchPolicy-LocalExecutionRole`.

If you're onboarding a management account—the account that you use to create an organization in AWS Organizations—Quick Setup also creates the following roles on your behalf:

- `AWS-QuickSetup-SSM-RoleForEnablingExplorer` – Grants permissions to the `AWS-EnableExplorer` automation runbook. The `AWS-EnableExplorer` runbook configures Explorer, a capability of Systems Manager, to display information for multiple AWS accounts and AWS Regions.

- `AWSServiceRoleForAmazonSSM` – A service-linked role that grants access to AWS resources managed and used by Systems Manager.
- `AWSServiceRoleForAmazonSSM_AccountDiscovery` – A service-linked role that grants permissions to Systems Manager to call AWS services to discover AWS account information when synchronizing data. For more information, see [Using roles to collect AWS account information for OpsCenter and Explorer](#).

When onboarding a management account, Quick Setup enables trusted access between AWS Organizations and CloudFormation to deploy Quick Setup configurations across your organization. To enable trusted access, your management account must have administrator permissions. After onboarding, you no longer need administrator permissions. For more information, see [Enable trusted access with Organizations](#).

For information about AWS Organizations account types, see [AWS Organizations terminology and concepts](#) in the *AWS Organizations User Guide*.

#### Note

Quick Setup uses AWS CloudFormation StackSets to deploy your configurations across AWS accounts and Regions. If the number of target accounts multiplied by the number of Regions exceeds 10,000, the configuration fails to deploy. We recommend reviewing your use case and creating configurations that use fewer targets to accommodate the growth of your organization. Stack instances aren't deployed to your organization's management account. For more information, see [Considerations when creating a stack set with service-managed permissions](#).

## Manual onboarding for working with Quick Setup API programmatically

If you use the console to work with Quick Setup, the service handles onboarding steps for you. If you plan to use SDKs or the AWS CLI to work with the Quick Setup API, you can still use the console to complete onboarding steps for you so you don't have to perform them manually. However, some customers need to complete onboarding steps for Quick Setup programmatically without interacting with the console. If this method fits your use case, you must complete the following steps. All of these steps must be completed from your AWS Organizations management account.

## To complete manual onboarding for Quick Setup

1. Activate trusted access for AWS CloudFormation with Organizations. This provides the management account with the permissions needed to create and manage StackSets for your organization. You can use AWS CloudFormation's `ActivateOrganizationsAccess` API action to complete this step. For more information, see [ActivateOrganizationsAccess](#) in the *AWS CloudFormation API Reference*.
2. Enable the integration of Systems Manager with Organizations. This allows Systems Manager to create a service-linked role in all the accounts in your organization. This also allows Systems Manager to perform operations on your behalf in your organization and its accounts. You can use AWS Organizations's `EnableAWSServiceAccess` API action to complete this step. The service principal for Systems Manager is `ssm.amazonaws.com`. For more information, see [EnableAWSServiceAccess](#) in the *AWS Organizations API Reference*.
3. Create the required IAM role for Explorer. This allows Quick Setup to create dashboards for your configurations so you can view deployment and association statuses. Create an IAM role and attach the `AWSSystemsManagerEnableExplorerExecutionPolicy` managed policy. Modify the trust policy for the role to match the following. Replace each *account ID* with your information.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": "ssm.amazonaws.com"
      },
      "Action": "sts:AssumeRole",
      "Condition": {
        "StringEquals": {
          "aws:SourceAccount": "account ID"
        },
        "ArnLike": {
          "aws:SourceArn": "arn:*:ssm:*:account ID:automation-execution/"
        }
      }
    }
  ]
}
```

```
}

```

4. Update the Quick Setup service setting for Explorer. You can use Quick Setup's `UpdateServiceSettings` API action to complete this step. Specify the ARN for the IAM role you created in the previous step for the `ExplorerEnablingRoleArn` request parameter. For more information, see [UpdateServiceSettings](#) in the *Quick Setup API Reference*.
5. Create the required IAM roles for AWS CloudFormation StackSets to use. You must create an *execution* role and an *administration* role.
  - a. Create the execution role. The execution role should have at least one of the `AWSQuickSetupDeploymentRolePolicy` or `AWSQuickSetupPatchPolicyDeploymentRolePolicy` managed policies attached. If you're only creating patch policy configurations, you can use `AWSQuickSetupPatchPolicyDeploymentRolePolicy` managed policy. All other configurations use the `AWSQuickSetupDeploymentRolePolicy` policy. Modify the trust policy for the role to match the following. Replace each *account ID* and *administration role name* with your information.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "AWS": "arn:aws:iam::account ID:role/administration role name"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

- b. Create the administration role. The permissions policy must match the following. Replace each *account ID* and *execution role name* with your information.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Action": [
        "sts:AssumeRole"
      ]
    }
  ]
}
```

```

    ],
    "Resource": "arn:*:iam::account ID:role/execution role name",
    "Effect": "Allow"
  }
]
}

```

Modify the trust policy for the role to match the following. Replace each *account ID* with your information.

```

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": "cloudformation.amazonaws.com"
      },
      "Action": "sts:AssumeRole",
      "Condition": {
        "StringEquals": {
          "aws:SourceAccount": "account ID"
        },
        "StringLike": {
          "aws:SourceArn": "arn:aws:cloudformation:*:account ID:stackset/AWS-QuickSetup-*"
        }
      }
    }
  ]
}

```

## Using a delegated administrator for Quick Setup

When you register a delegated administrator account for Quick Setup, you can create, update, view, and delete Quick Setup configuration managers that target organizational units in an Organizations. You'll also be able to use the delegated administrator account to manage configuration managers created by the management account of your organization.

The management account of an AWS Organizations organization can register one account within your organization as a delegated administrator. When you register an account as a delegated

administrator for Quick Setup, the account is also registered as a delegated administrator for AWS CloudFormation StackSets and Explorer because these are dependent services used to deploy and monitor Quick Setup configurations.

### Note

At this time, the patch policy configuration type isn't supported by the delegated administrator for Quick Setup.

The following topics describe how to register and deregister a delegated administrator for Quick Setup.

## Topics

- [Register a delegated administrator for Quick Setup](#)
- [Deregister a delegated administrator for Quick Setup](#)

## Register a delegated administrator for Quick Setup

Use the following procedure to register a delegated administrator for Quick Setup.

### To register a Quick Setup delegated administrator

1. Log into your AWS Organizations management account.
2. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
3. In the navigation pane, choose **Quick Setup**.
4. Choose **Settings**.
5. In the **Delegated administrator for Quick Setup** section, verify that you have configured the required service-linked role and service access options. If necessary, choose the **Create role** and **Enable access** buttons to configure these options.
6. For **Account ID**, enter the AWS account ID. This account must be a member account in AWS Organizations.
7. Choose **Register delegated administrator**.

## Deregister a delegated administrator for Quick Setup

Use the following procedure to deregister a delegated administrator for Quick Setup.

### To deregister a Quick Setup delegated administrator

1. Log into your AWS Organizations management account.
2. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
3. In the navigation pane, choose **Quick Setup**.
4. Choose **Settings**.
5. In the **Delegated administrator for Quick Setup** section, choose **Deregister** from the **Actions** dropdown.
6. Select **Confirm**.

## Learn Quick Setup terminology and details

Quick Setup, a capability of AWS Systems Manager, displays the results of all configuration managers you've created across all AWS Regions in the **Configuration managers** table on the Quick Setup home page. From this page, you can **View details** of each configuration, delete configurations from the **Actions** drop down, or **Create** configurations. The **Configuration managers** table contains the following information:

- **Name** – The name of the configuration manager if provided when created.
- **Configuration type** – The configuration type chosen when creating the configuration.
- **Version** – The version of the configuration type currently deployed.
- **Organizational units** – Displays the organizational units (OUs) that the configuration is deployed to if you chose a **Custom** set of targets. Organizational units and custom targets are only available to the management account of your organization. The management account is the account that you use to create an organization in AWS Organizations.
- **Deployment type** – Indicates whether the deployment applies to the entire organization (**Organizational**) or only your account (**Local**).
- **Regions** – The Regions that the configuration is deployed to if you chose a **Custom** set of targets or targets within your **Current account**.

- **Deployment status** – The deployment status indicates if AWS CloudFormation successfully deployed the target or stack instance. The target and stack instances contain the configuration options that you chose during configuration creation.
- **Association status** – The association status is the state of all associations created by the configuration that you created. The associations for all targets must run successfully; otherwise, the status is **Failed**.

Quick Setup creates and runs a State Manager association for each configuration target. State Manager is a capability of AWS Systems Manager.

To view configurations deployed to the Region you're currently browsing, select the **Configurations** tab.

## Configuration details

The **Configuration details** page displays information about the deployment of the configuration and its related associations. From this page, you can edit configuration options, update targets, or delete the configuration. You can also view the details of each configuration deployment to get more information about the associations.

Depending on the type of configuration, one or more of the following status graphs are displayed:

### Configuration deployment status

Displays the number of deployments that have succeeded, failed, or are running or pending. Deployments occur in the specified target accounts and Regions that contain nodes affected by the configuration.

### Configuration association status

Displays the number of State Manager associations that have succeeded, failed, or are pending. Quick Setup creates an association in each deployment for the configuration options selected.

### Setup status

Displays the number of actions performed by the configuration type and their current statuses.

### Resource compliance

Displays the number of resources that are compliant to the configurations specified policy.

The **Configuration details** table displays information about the deployment of your configuration. You can view more details about each deployment by selecting the deployment and then choosing **View details**. The details page of each deployment displays the associations deployed to the nodes in that deployment.

## Editing and deleting your configuration

You can edit configuration options of a configuration from the **Configuration details** page by choosing **Actions** and then **Edit configuration options**. When you add new options to the configuration, Quick Setup runs your deployments and creates new associations. When you remove options from a configuration, Quick Setup runs your deployments and removes any related associations.

### Note

You can edit Quick Setup configurations for your account at anytime. To edit an **Organization** configuration, the **Configuration status** must be **Success** or **Failed**.

You can also update the targets included in your configurations by choosing **Actions** and **Add OUs, Add Regions, Remove OUs, or Remove Regions**. If your account isn't configured as the management account or you created the configuration for only the current account, you can't update the target organizational units (OUs). Removing a Region or OU removes the associations from those Regions or OUs.

Periodically, Quick Setup releases new versions of configurations. You can select the **Upgrade configuration** option to upgrade your configuration to the latest version.

You can delete a configuration from Quick Setup by choosing the configuration, then **Actions**, and then **Delete configuration**. Or, you can delete the configuration from the **Configuration details** page under the **Actions** dropdown and then **Delete configuration**. Quick Setup then prompts you to **Remove all OUs and Regions** which might take some time to complete. Deleting a configuration also deletes all related associations. This two-step deletion process removes all deployed resources from all accounts and Regions and then deletes the configuration.

## Configuration compliance

You can view whether your instances are compliant with the associations created by your configurations in either Explorer or Compliance, which are both capabilities of AWS Systems

Manager. To learn more about compliance, see [Learn details about Compliance](#). To learn more about viewing compliance in Explorer, see [AWS Systems Manager Explorer](#).

## Using the Quick Setup API to manage configurations and deployments

You can use the API provided by Quick Setup to create and manage configurations and deployments using the AWS CLI or your preferred SDK. You can also use AWS CloudFormation to create a configuration manager resource that deploys configurations. Using the API, you create configuration managers that deploy configuration *definitions*. Configuration definitions contain all of the necessary information to deploy a particular configuration type. For more information about the Quick Setup API, see the [Quick Setup API Reference](#).

The following examples demonstrate how to create configuration managers using the AWS CLI and AWS CloudFormation.

### AWS CLI

```
aws ssm-quicksetup create-configuration-manager \
--name configuration manager name \
--description Description of your configuration manager
--configuration-definitions JSON string containing configuration definition
```

The following is an example JSON string containing a configuration definition for patch policy.

```
{
  "Type": "AWSQuickSetupType-PatchPolicy",
  "LocalDeploymentAdministrationRoleArn": "arn:aws:iam::123456789012:role/AWS-QuickSetup-StackSet-Local-AdministrationRole",
  "LocalDeploymentExecutionRoleName": "AWS-QuickSetup-StackSet-Local-ExecutionRole",
  "Parameters": {
    "ConfigurationOptionsInstallNextInterval": "true",
    "ConfigurationOptionsInstallValue": "cron(0 2 ? * SAT#1 * *)",
    "ConfigurationOptionsPatchOperation": "ScanAndInstall",

## Supported Quick Setup configuration types

### Supported configuration types

Quick Setup walks you through configuring operational best practices for a number of Systems Manager and other AWS services, and automatically deploying those configurations. The Quick Setup dashboard displays a real-time view of your configuration deployment status.

You can use Quick Setup in an individual AWS account or across multiple AWS accounts and Regions by integrating with AWS Organizations. Using Quick Setup across multiple accounts helps to ensure that your organization maintains consistent configurations.

Quick Setup provides support for the following configuration types.

- [Set up Amazon EC2 host management using Quick Setup](#)
- [Set up the Default Host Management Configuration for an organization using Quick Setup](#)
- [Create an AWS Config configuration recorder using Quick Setup](#)

- [Deploy AWS Config conformance pack using Quick Setup](#)
- [Configure patching for instances in an organization using Quick Setup](#)
- [Change Manager organization setup](#)
- [Set up DevOps Guru using Quick Setup](#)
- [Deploy Distributor packages using Quick Setup](#)
- [Stop and start EC2 instances automatically on a schedule using Quick Setup](#)
- [OpsCenter organization setup](#)
- [Configure AWS Resource Explorer using Quick Setup](#)

## Set up Amazon EC2 host management using Quick Setup

Use Quick Setup, a capability of AWS Systems Manager, to quickly configure required security roles and commonly used Systems Manager capabilities on your Amazon Elastic Compute Cloud (Amazon EC2) instances. You can use Quick Setup in an individual account or across multiple accounts and AWS Regions by integrating with AWS Organizations. These capabilities help you manage and monitor the health of your instances while providing the minimum required permissions to get started.

If you're unfamiliar with Systems Manager services and features, we recommend that you review the *AWS Systems Manager User Guide* before creating a configuration with Quick Setup. For more information about Systems Manager, see [What is AWS Systems Manager?](#).

### Important

Quick Setup might not be the right tool to use for EC2 management if either of the following applies to you:

- You're trying to create an EC2 instance for the first time to try out AWS capabilities.
- You're still new to EC2 instance management.

Instead, we recommend that you explore the following content:

- [Getting Started with Amazon EC2](#)
- [Launch an instance using the new launch instance wizard](#) in the *Amazon EC2 User Guide*
- [Launch an instance using the new launch instance wizard](#) in the *Amazon EC2 User Guide*

- [Tutorial: Get started with Amazon EC2 Linux instances](#) in the *Amazon EC2 User Guide*

If you're already familiar with EC2 instance management and want to streamline configuration and management for multiple EC2 instances, use Quick Setup. Whether your organization has dozens, thousands, or millions of EC2 instances, use the following Quick Setup procedure to configure multiple options for them, all at once.

### Note

This configuration type lets you set multiple options for an entire organization defined in AWS Organizations, only some organizational accounts and Regions, or a single account. One of these options is to check for and apply updates to SSM Agent every two weeks. If you are an organization administrator, you can also choose to update *all* EC2 instances in your organization with agent updates every two weeks using the Default Host Management Configuration type. For information, see [Set up the Default Host Management Configuration for an organization using Quick Setup](#).

## Configuring host management options for EC2 instances

To set up host management, perform the following tasks in the AWS Systems Manager Quick Setup console.

### To open the Host Management configuration page

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Quick Setup**.
3. On the **Host Management** card, choose **Create**.

### Tip

If you already have one or more configurations in your account, first choose the **Library** tab or the **Create** button in the **Configurations** section to view the cards.

## To configure Systems Manager host management options

- To configure Systems Manager functionality, in the **Configuration options** section, choose the options in the **Systems Manager** group that you want to enable for your configuration:

### Update Systems Manager (SSM) Agent every two weeks

Enables Systems Manager to check every two weeks for a new version of the agent. If there is a new version, then Systems Manager automatically updates the agent on your managed node to the latest released version. Quick Setup doesn't install the agent on instances where it's not already present. For information about which AMIs have SSM Agent preinstalled, see [Find AMIs with the SSM Agent preinstalled](#).

We encourage you to choose this option to ensure that your nodes are always running the most up-to-date version of SSM Agent. For more information about SSM Agent, including information about how to manually install the agent, see [Working with SSM Agent](#).

### Collect inventory from your instances every 30 minutes

Enables Quick Setup to configure collection of the following types of metadata:

- **AWS components** – EC2 driver, agents, versions, and more.
- **Applications** – Application names, publishers, versions, and more.
- **Node details** – System name, operating system (OS) name, OS version, last boot, DNS, domain, work group, OS architecture, and more.
- **Network configuration** – IP address, MAC address, DNS, gateway, subnet mask, and more.
- **Services** – Name, display name, status, dependent services, service type, start type, and more (Windows Server nodes only).
- **Windows roles** – Name, display name, path, feature type, installed state, and more (Windows Server nodes only).
- **Windows updates** – Hotfix ID, installed by, installed date, and more (Windows Server nodes only).

For more information about Inventory, a capability of AWS Systems Manager, see [AWS Systems Manager Inventory](#).

**Note**

The **Inventory collection** option can take up to 10 minutes to complete, even if you only selected a few nodes.

## Scan instances for missing patches daily

Enables Patch Manager, a capability of Systems Manager, to scan your nodes daily and generate a report in the **Compliance** page. The report shows how many nodes are patch-compliant according to the *default patch baseline*. The report includes a list of each node and its compliance status.

For information about patching operations and patch baselines, see [AWS Systems Manager Patch Manager](#).

For information about patch compliance, see the Systems Manager [Compliance](#) page.

For information about patching managed nodes in multiple accounts and Regions in one configuration, see [Patch policy configurations in Quick Setup](#) and [Configure patching for instances in an organization using Quick Setup](#).

**Important**

Systems Manager supports several methods for scanning managed nodes for patch compliance. If you implement more than one of these methods at a time, the patch compliance information you see is always the result of the most recent scan. Results from previous scans are overwritten. If the scanning methods use different patch baselines, with different approval rules, the patch compliance information can change unexpectedly. For more information, see [Avoiding unintentional patch compliance data overwrites](#).

## To configure Amazon CloudWatch host management options

- To configure CloudWatch functionality, in the **Configuration options** section, choose the options in the **Amazon CloudWatch** group that you want to enable for your configuration:

## Install and configure the CloudWatch agent

Installs the basic configuration of the unified CloudWatch agent on your Amazon EC2 instances. The agent collects metrics and log files from your instances for Amazon CloudWatch. This information is consolidated so you can quickly determine the health of your instances. For more information about the CloudWatch agent basic configuration, see [CloudWatch agent predefined metric sets](#). There might be added cost. For more information, see [Amazon CloudWatch pricing](#).

## Update the CloudWatch agent once every 30 days

Enables Systems Manager to check every 30 days for a new version of the CloudWatch agent. If there is a new version, Systems Manager updates the agent on your instance. We encourage you to choose this option to ensure that your instances are always running the most up-to-date version of the CloudWatch agent.

## To configure Amazon EC2 Launch Agent host management options

- To configure Amazon EC2 Launch Agent functionality, in the **Configuration options** section, choose the options in the **Amazon EC2 Launch Agent** group that you want to enable for your configuration:

## Update the EC2 launch agent once every 30 days

Enables Systems Manager to check every 30 days for a new version of the launch agent installed on your instance. If a new version is available, Systems Manager updates the agent on your instance. We encourage you to choose this option to ensure that your instances are always running the most up-to-date version of the applicable launch agent. For Amazon EC2 Windows instances, this option supports EC2Launch, EC2Launch v2, and EC2Config. For Amazon EC2 Linux instances, this option supports `cloud-init`. For Amazon EC2 Mac instances, this option supports `ec2-macos-init`. Quick Setup doesn't support updating launch agents that are installed on operating systems not supported by the launch agent, or on AL2023.

For more information about these initialization agents see the following topics:

- [Configure a Windows instance using EC2Launch v2](#)
- [Configure a Windows instance using EC2Launch](#)
- [Configure a Windows instance using the EC2Config service](#)
- [cloud-init Documentation](#)
- [ec2-macos-init](#)

## To select the EC2 instances to be updated by the host management configuration

- In the **Targets** section, choose the method to determine the accounts and Regions where the configuration is to be deployed:

### **Note**

You can't create multiple Quick Setup Host Management configurations that target the same AWS Region.

## Entire organization

Your configuration is deployed to all organizational units (OUs) and AWS Regions in your organization.

### **Note**

The **Entire organization** option is only available if you're configuring host management from your organization's management account.

## Custom

1. In the **Target OUs** section, select the OUs where you want to deploy this host management configuration.
2. In the **Target Regions** section, select the Regions where you want to deploy this host management configuration.

## Current account

Choose one of the Region options and follow the steps for that option.

## Current Region

Choose how to target instances in the current Region only:

- **All instances** – The host management configuration automatically targets every EC2 in the current Region.
- **Tag** – Choose **Add** and enter the key and optional value that is added to the instances to be targeted.
- **Resource group** – For **Resource group**, select an existing resource group that contains the EC2 instances to be targeted.
- **Manual** – In the **Instances** section, select the check box of each EC2 instance to be targeted.

## Choose Regions

Choose how to target instances in the Region you specify by choosing one of the following:

- **All instances** – All instances in the Regions you specify are targeted.
- **Tag** – Choose **Add** and enter the key and optional value that has been added to the instances to be targeted.

In the **Target Regions** section, select the Regions where you want to deploy this host management configuration.

## To specify an instance profile option

- **Entire organization and Custom targets only.**

In the **Instance profile options** section, choose whether you want to add the required IAM policies to the existing instance profiles attached to your instances, or to allow Quick Setup to create the IAM policies and instance profiles with the permissions needed for the configuration you choose.

After specifying all your configuration choices, choose **Create**.

## Set up the Default Host Management Configuration for an organization using Quick Setup

With Quick Setup, a capability of AWS Systems Manager, you can activate Default Host Management Configuration for all accounts and Regions that have been added to your organization in AWS Organizations. This ensures that SSM Agent is kept up to date on all Amazon Elastic Compute Cloud (EC2) instances in the organization, and that they can connect to Systems Manager.

### Before you begin

Ensure that the following requirements are met before enabling this setting.

- The latest version of SSM Agent is already installed on all EC2 instances to be managed in your organization.
- Your EC2 instances to be managed are using Instance Metadata Service Version 2 (IMDSv2).
- You are signed in to the management account for your organization, as specified in AWS Organizations, using an AWS Identity and Access Management (IAM) identity (user, role, or group) with administrator permissions.

### Using the default EC2 instance management role

Default Host Management Configuration makes use of the `default-ec2-instance-management-role` service setting for Systems Manager. This is a role with permissions that you want made available to all accounts in your organization to allow communication between SSM Agent on the instance and the Systems Manager service in the cloud.

If you have already set this role using the [update-service-setting](#) CLI command, Default Host Management Configuration uses that role. If you have not set this role yet, Quick Setup will create and apply the role for you.

To check whether this role has already been specified for your organization, use the [get-service-setting](#) command.

### Enable automatic updates of SSM Agent every two weeks

Use the following procedure to enable the Default Host Management Configuration option for your entire AWS Organizations organization.

## To enable automatic updates of SSM Agent every two weeks

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Quick Setup**.
3. On the **Default Host Management Configuration** card, choose **Create**.

### Tip

If you already have one or more configurations in your account, first choose the **Library** tab or the **Create** button in the **Configurations** section to view the cards.

4. In the **Configuration options** section, select **Enable automatic updates of SSM Agent every two weeks**.
5. Choose **Create**

## Create an AWS Config configuration recorder using Quick Setup

With Quick Setup, a capability of AWS Systems Manager, you can quickly create a configuration recorder powered by AWS Config. Use the configuration recorder to detect changes in your resource configurations and capture the changes as configuration items. If you're unfamiliar with AWS Config, we recommend learning more about the service by reviewing the content in the *AWS Config Developer Guide* before creating a configuration with Quick Setup. For more information about AWS Config, see [What is AWS Config?](#) in the *AWS Config Developer Guide*.

By default, the configuration recorder records all supported resources in the AWS Region where AWS Config is running. You can customize the configuration so that only the resource types you specify are recorded. For more information, see [Selecting which resources AWS Config records](#) in the *AWS Config Developer Guide*.

You're charged service usage fees when AWS Config starts recording configurations. For pricing information, see [AWS Config pricing](#).

### Note

If you've already created a configuration recorder, Quick Setup doesn't stop recording or make any changes to resource types that you're already recording. If you choose to record additional resource types using Quick Setup, the service appends them to your

existing recorder groups. Deleting the Quick Setup **Config recording** configuration type doesn't stop the configuration recorder. Changes continue to be recorded, and service usage fees apply until you stop the configuration recorder. To learn more about managing the configuration recorder, see [Managing the Configuration Recorder](#) in the *AWS Config Developer Guide*.

To set up AWS Config recording, perform the following tasks in the AWS Systems Manager console.

### To set up AWS Config recording with Quick Setup

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Quick Setup**.
3. On the **Config Recording** card, choose **Create**.

#### Tip

If you already have one or more configurations in your account, first choose the **Library** tab or the **Create** button in the **Configurations** section to view the cards.

4. In the **Configuration options** section, do the following:
  - a. For **Choose the AWS resource types to record**, specify whether to record all supported resources or only the resource types you choose.
  - b. For **Delivery settings, specify whether to create a new Amazon Simple Storage Service (Amazon S3) bucket, or choose an existing bucket to send configuration snapshots to**.
  - c. For **Notification options**, choose the notification option you prefer. AWS Config uses Amazon Simple Notification Service (Amazon SNS) to notify you about important AWS Config events related to your resources. If you choose the **Use existing SNS topics** option, you must provide the AWS account ID and name of the existing Amazon SNS topic in that account you want to use. If you target multiple AWS Regions, the topic names must be identical in each Region.
5. In the **Schedule** section, choose how frequently you want Quick Setup to remediate changes made to resources that differ from your configuration. The **Default** option runs once. If you don't want Quick Setup to remediate changes made to resources that differ from your configuration, choose **Disable remediation** under **Custom**.

6. In the **Targets** section, choose one of the following to identify the accounts and Regions for recording.

 **Note**

If you are working in a single account, options for working with organizations and organizational units (OUs) are not available. You can choose whether to apply this configuration to all AWS Regions in your account or only the Regions you select.

- **Entire organization** – All accounts and Regions in your organization.
  - **Custom** – Only the OUs and Regions that you specify.
    - In the **Target OUs** section, select the OUs where you want to allow recording.
    - In the **Target Regions** section, select the Regions where you want to allow recording.
  - **Current account** – Only the Regions you specify in the account you are currently signed into are targeted. Choose one of the following:
    - **Current Region** – Only managed nodes in the Region selected in the console are targeted.
    - **Choose Regions** – Choose the individual Regions to apply the recording configuration to.
7. Choose **Create**.

## Deploy AWS Config conformance pack using Quick Setup

A conformance pack is a collection of AWS Config rules and remediation actions. With Quick Setup, you can deploy a conformance pack as a single entity in an account and an AWS Region or across an organization in AWS Organizations. This helps you manage configuration compliance of your AWS resources at scale, from policy definition to auditing and aggregated reporting, by using a common framework and packaging model.

To deploy conformance packs, perform the following tasks in the AWS Systems Manager Quick Setup console.

 **Note**

You must enable AWS Config recording before deploying this configuration. For more information, see [Conformance packs](#) in the *AWS Config Developer Guide*.

## To deploy conformance packs with Quick Setup

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Quick Setup**.
3. On the **Conformance Packs** card, choose **Create**.

### Tip

If you already have one or more configurations in your account, first choose the **Library** tab or the **Create** button in the **Configurations** section to view the cards.

4. In the **Choose conformance packs** section, choose the conformance packs you want to deploy.
5. In the **Schedule** section, choose how frequently you want Quick Setup to remediate changes made to resources that differ from your configuration. The **Default** option runs once. If you don't want Quick Setup to remediate changes made to resources that differ from your configuration, choose **Disabled** under **Custom**.
6. In the **Targets** section, choose whether to deploy conformance packs to your entire organization, some AWS Regions, or the account you're currently logged in to.

If you choose **Entire organization**, continue to step 8.

If you choose **Custom**, continue to step 7.

7. In the **Target Regions** section, select the check boxes of the Regions you want to deploy conformance packs to.
8. Choose **Create**.

## Configure patching for instances in an organization using Quick Setup

With Quick Setup, a capability of AWS Systems Manager, you can create patch policies powered by Patch Manager. A patch policy defines the schedule and baseline to use when automatically patching your Amazon Elastic Compute Cloud (Amazon EC2) instances and other managed nodes. Using a single patch policy configuration, you can define patching for all accounts in multiple AWS Regions in your organization, for only the accounts and Regions you choose, or for a single account-Region pair. For more information about patch policies, see [Patch policy configurations in Quick Setup](#).

## Prerequisite

To define a patch policy for a node using Quick Setup, the node must be a *managed node*. For more information about managing your nodes, see [Setting up Systems Manager unified console for an organization](#).

### Important

**Patch compliance scanning methods** – Systems Manager supports several methods for scanning managed nodes for patch compliance. If you implement more than one of these methods at a time, the patch compliance information you see is always the result of the most recent scan. Results from previous scans are overwritten. If the scanning methods use different patch baselines, with different approval rules, the patch compliance information can change unexpectedly. For more information, see [Avoiding unintentional patch compliance data overwrites](#).

**Association compliance status and patch policies** – The patching status for a managed node that's under a Quick Setup patch policy matches the status of the State Manager association execution for that node. If the association execution status is `Compliant`, the patching status for the managed node is also marked `Compliant`. If the association execution status is `Non-Compliant`, the patching status for the managed node is also marked `Non-Compliant`.

## Supported Regions for patch policy configurations

Patch policy configurations in Quick Setup are currently supported in the following Regions:

- US East (Ohio) (us-east-2)
- US East (N. Virginia) (us-east-1)
- US West (N. California) (us-west-1)
- US West (Oregon) (us-west-2)
- Asia Pacific (Mumbai) (ap-south-1)
- Asia Pacific (Seoul) (ap-northeast-2)
- Asia Pacific (Singapore) (ap-southeast-1)
- Asia Pacific (Sydney) (ap-southeast-2)
- Asia Pacific (Tokyo) (ap-northeast-1)

- Canada (Central) (ca-central-1)
- Europe (Frankfurt) (eu-central-1)
- Europe (Ireland) (eu-west-1)
- Europe (London) (eu-west-2)
- Europe (Paris) (eu-west-3)
- Europe (Stockholm) (eu-north-1)
- South America (São Paulo) (sa-east-1)

## Permissions for the patch policy S3 bucket

When you create a patch policy, Quick Setup creates an Amazon S3 bucket that contains a file named `baseline_overrides.json`. This file stores information about the patch baselines that you specified for your patch policy.

The S3 bucket is named in the format `aws-quicksetup-patchpolicy-account-id-quick-setup-configuration-id`.

For example: `aws-quicksetup-patchpolicy-123456789012-abcde`

If you're creating a patch policy for an organization, the bucket is created in your organization's management account.

There are two use cases when you must provide other AWS resources with permission to access this S3 bucket using AWS Identity and Access Management (IAM) policies:

- [Case 1: Use your own instance profile or service role with your managed nodes instead of one provided by Quick Setup](#)
- [Case 2: Use VPC endpoints to connect to Systems Manager](#)

The permissions policy you need in either case is located in the section below, [Policy permissions for Quick Setup S3 buckets](#).

### Case 1: Use your own instance profile or service role with your managed nodes instead of one provided by Quick Setup

Patch policy configurations include an option to **Add required IAM policies to existing instance profiles attached to your instances**.

If you don't choose this option but want Quick Setup to patch your managed nodes using this patch policy, you must ensure that the following are implemented:

- The IAM managed policy `AmazonSSMManagedInstanceCore` must be attached to the [IAM instance profile](#) or [IAM service role](#) that's used to provide Systems Manager permissions to your managed nodes.
- You must add permissions to access your patch policy bucket as an inline policy to the IAM instance profile or IAM service role. You can provide wildcard access to all `aws-quicksetup-patchpolicy` buckets or only the specific bucket created for your organization or account, as shown in the earlier code samples.
- You must tag your IAM instance profile or IAM service role with the following key-value pair.

Key: `QSConfigId-quick-setup-configuration-id`, Value: `quick-setup-configuration-id`

`quick-setup-configuration-id` represents the value of the parameter applied to the AWS CloudFormation stack that is used in creating your patch policy configuration. To retrieve this ID, do the following:

1. Open the AWS CloudFormation console at <https://console.aws.amazon.com/cloudformation>.
2. Select the name of the stack that is used to create your patch policy. The name is in a format such as `StackSet-AWS-QuickSetup-PatchPolicy-LA-q4bkg-52cd2f06-d0f9-499e-9818-d887cEXAMPLE`.
3. Choose the **Parameters** tab.
4. In the **Parameters** list, in the **Key** column, locate the key **QSConfigurationId**. In the **Value** column for its row, locate the configuration ID, such as `abcde`.

In this example, for the tag to apply to your instance profile or service role, the key is `QSConfigId-abcde`, and the value is `abcde`.

For information about adding tags to an IAM role, see [Tagging IAM roles](#) and [Managing tags on instance profiles \(AWS CLI or AWS API\)](#) in the *IAM User Guide*.

## Case 2: Use VPC endpoints to connect to Systems Manager

If you use VPC endpoints to connect to Systems Manager, your VPC endpoint policy for S3 must allow access to your Quick Setup patch policy S3 bucket.

For information about adding permissions to a VPC endpoint policy for S3, see [Controlling access from VPC endpoints with bucket policies](#) in the *Amazon S3 User Guide*.

## Policy permissions for Quick Setup S3 buckets

You can provide wildcard access to all `aws-quicksetup-patchpolicy` buckets or only the specific bucket created for your organization or account. To provide the necessary permissions for the two cases described below, use either format.

### All patch policy buckets

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AccessToAllPatchPolicyRelatedBuckets",
      "Effect": "Allow",
      "Action": "s3:GetObject",
      "Resource": "arn:aws:s3::aws-quicksetup-patchpolicy-*"
    }
  ]
}
```

### Specific patch policy bucket

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AccessToMyPatchPolicyRelatedBucket",
      "Effect": "Allow",
      "Action": "s3:GetObject",
      "Resource": "arn:aws:s3::aws-quicksetup-patchpolicy-account-id-quick-setup-configuration-id"1
    }
  ]
}
```

<sup>1</sup>After the patch policy configuration is created, you can locate the full name of your bucket in the S3 console. For example: `aws-quicksetup-patchpolicy-123456789012-abcde`

## Random patch baseline IDs in patch policy operations

Patching operations for patch policies utilize the `BaselineOverride` parameter in the `AWS-RunPatchBaseline` SSM Command document.

When you use `AWS-RunPatchBaseline` for patching *outside* of a patch policy, you can use `BaselineOverride` to specify a list of patch baselines to use during the operation that are different from the specified defaults. You create this list in a file named `baseline_overrides.json` and manually add it to an Amazon S3 bucket that you own, as explained in [Using the `BaselineOverride` parameter](#).

For patching operations based on patch policies, however, Systems Manager automatically creates an S3 bucket and adds a `baseline_overrides.json` file to it. Then, every time Quick Setup runs a patching operation (using the Run Command) capability, the system generates a random ID for each patch baseline. This ID is different for every patch policy patching operation, and the patch baseline it represents is not stored or accessible to you in your account.

As a result, you will not see the ID of the patch baseline selected in your configuration in patching logs. This applies to both AWS managed patch baselines and custom patch baselines you might have selected. The baseline ID reported in the log is instead that one that was generated for that specific patching operation.

In addition, if you attempt to view details in Patch Manager about a patch baseline that was generated with a random ID, the system reports that the patch baseline doesn't exist. This is expected behavior and can be ignored.

## Creating a patch policy

To create a patch policy, perform the following tasks in the Systems Manager console.

### To create a patch policy with Quick Setup

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.

If you are setting up patching for an organization, make sure you are signed in to the management account for the organization. You can't set up the policy using the delegated administrator account or a member account.

2. In the navigation pane, choose **Quick Setup**.

3. On the **Patch Manager** card, choose **Create**.

 **Tip**

If you already have one or more configurations in your account, first choose the **Library** tab or the **Create** button in the **Configurations** section to view the cards.

4. For **Configuration name**, enter a name to help identify the patch policy.
5. In the **Scanning and installation** section, under **Patch operation**, choose whether the patch policy will **Scan** the specified targets or **Scan and install** patches on the specified targets.
6. Under **Scanning schedule**, choose **Use recommended defaults** or **Custom scan schedule**. The default scan schedule will scan your targets daily at 1:00 AM UTC.
  - If you choose **Custom scan schedule**, select the **Scanning frequency**.
  - If you choose **Daily**, enter the time, in UTC, that you want to scan your targets.
  - If you choose **Custom CRON Expression**, enter the schedule as a **CRON expression**. For more information about formatting CRON expressions for Systems Manager, see [Reference: Cron and rate expressions for Systems Manager](#).

Also, select **Wait to scan targets until first CRON interval**. By default, Patch Manager immediately scans nodes as they become targets.

7. If you chose **Scan and install**, choose the **Installation schedule** to use when installing patches to the specified targets. If you choose **Use recommended defaults**, Patch Manager will install weekly patches at 2:00 AM UTC on Sunday.
  - If you choose **Custom install schedule**, select the **Installation Frequency**.
  - If you choose **Daily**, enter the time, in UTC, that you want to install updates on your targets.
  - If you choose **Custom CRON expression**, enter the schedule as a **CRON expression**. For more information about formatting CRON expressions for Systems Manager, see [Reference: Cron and rate expressions for Systems Manager](#).

Also, clear **Wait to install updates until first CRON interval** to immediately install updates on nodes as they become targets. By default, Patch Manager waits until the first CRON interval to install updates.

- Choose **Reboot if needed** to reboot the nodes after patch installation. Rebooting after installation is recommended but can cause availability issues.

8. In the **Patch baseline** section, choose the patch baselines to use when scanning and updating your targets.

By default, Patch Manager uses the predefined patch baselines. For more information, see [Predefined baselines](#).

If you choose **Custom patch baseline**, change the selected patch baseline for operating systems that you don't want to use a predefined AWS patch baseline.

 **Note**

If you use VPC endpoints to connect to Systems Manager, make sure your VPC endpoint policy for S3 allows access to this S3 bucket. For more information, see [Permissions for the patch policy S3 bucket](#).

 **Important**

If you are using a [patch policy configuration](#) in Quick Setup, updates you make to custom patch baselines are synchronized with Quick Setup once an hour.

If a custom patch baseline that was referenced in a patch policy is deleted, a banner displays on the Quick Setup **Configuration details** page for your patch policy. The banner informs you that the patch policy references a patch baseline that no longer exists, and that subsequent patching operations will fail. In this case, return to the Quick Setup **Configurations** page, select the Patch Manager configuration, and choose **Actions, Edit configuration**. The deleted patch baseline name is highlighted, and you must select a new patch baseline for the affected operating system.

9. (Optional) In the **Patching log storage** section, select **Write output to S3 bucket** to store patching operation logs in an Amazon S3 bucket.

 **Note**

If you are setting up a patch policy for an organization, the management account for your organization must have at least read-only permissions for this bucket. All organization units included in the policy must have write-access to the bucket. For information about granting bucket access to different accounts, see [Example 2: Bucket](#)

[owner granting cross-account bucket permissions](#) in the *Amazon Simple Storage Service User Guide*.

10. Choose **Browse S3** to select the bucket that you want to store patch log output in. The management account must have read access to this bucket. All non-management accounts and targets configured in the **Targets** section must have write access to the provided S3 bucket for logging.
11. In the **Targets** section, choose one of the following to identify the accounts and Regions for this patch policy operation.

 **Note**

If you are working in a single account, options for working with organizations and organizational units (OUs) are not available. You can choose whether to apply this configuration to all AWS Regions in your account or only the Regions you select. If you previously specified a Home Region for your account and haven't onboarded to the new Quick Setup console experience, you can't exclude that Region from the **Targets** configuration.

- **Entire organization** – All accounts and Regions in your organization.
  - **Custom** – Only the OUs and Regions that you specify.
    - In the **Target OUs** section, select the OUs where you want to set up the patch policy.
    - In the **Target Regions** section, select the Regions where you want to apply the patch policy.
  - **Current account** – Only the Regions you specify in the account you are currently signed into are targeted. Choose one of the following:
    - **Current Region** – Only managed nodes in the Region selected in the console are targeted.
    - **Choose Regions** – Choose the individual Regions to apply the patch policy to.
12. For **Choose how you want to target instances**, choose one of the following to identify the nodes to patch:
    - **All managed nodes** – All managed nodes in the selected OUs and Regions.
    - **Specify the resource group** – Choose the name of a resource group from the list to target its associated resources.

**Note**

Currently, selecting resource groups is supported only for single account configurations. To patch resources in multiple accounts, choose a different targeting option.

- **Specify a node tag** – Only nodes tagged with the key-value pair that you specify are patched in all accounts and Regions you have targeted.
- **Manual** – Choose managed nodes from all specified accounts and Regions manually from a list.

**Note**

This option currently supports only Amazon EC2 instances.

13. In the **Rate control** section, do the following:

- For **Concurrency**, enter a number or percentage of nodes to run the patch policy on at the same time.
- For **Error threshold**, enter the number or percentage of nodes that can experience an error before the patch policy fails.

14. (Optional) Select the **Add required IAM policies to existing instance profiles attached to your instances** check box.

This selection applies the IAM policies created by this Quick Setup configuration to nodes that already have an instance profile attached (EC2 instances) or a service role attached (hybrid-activated nodes). We recommend this selection when your managed nodes already have an instance profile or service role attached, but it doesn't contain all the permissions required for working with Systems Manager.

Your selection here is applied to managed nodes created later in the accounts and Regions that this patch policy configuration applies to.

**Important**

If you don't select this check box but want Quick Setup to patch your managed nodes using this patch policy, you must do the following:

Add permissions to your [IAM instance profile](#) or [IAM service role](#) to access the S3 bucket created for your patch policy  
Tag your IAM instance profile or IAM service role with a specific key-value pair.  
For information, see [Case 1: Use your own instance profile or service role with your managed nodes instead of one provided by Quick Setup](#).

## 15. Choose **Create**.

To review patching status after the patch policy is created, you can access the configuration from the [Quick Setup](#) page.

## Set up DevOps Guru using Quick Setup

You can quickly configure DevOps Guru options by using Quick Setup. Amazon DevOps Guru is a machine learning (ML) powered service that makes it easy to improve an application's operational performance and availability. DevOps Guru detects behaviors that are different from normal operating patterns so you can identify operational issues long before they impact your customers. DevOps Guru automatically ingests operational data from your AWS applications and provides a single dashboard to visualize issues in your operational data. You can get started with DevOps Guru to improve application availability and reliability with no manual setup or machine learning expertise.

Configuring DevOps Guru with Quick Setup is available in the following AWS Regions:

- US East (N. Virginia)
- US East (Ohio)
- US West (Oregon)
- Europe (Frankfurt)
- Europe (Ireland)
- Europe (Stockholm)
- Asia Pacific (Singapore)
- Asia Pacific (Sydney)
- Asia Pacific (Tokyo)

For pricing information, see [Amazon DevOps Guru pricing](#).

To set up DevOps Guru, perform the following tasks in the AWS Systems Manager Quick Setup console.

### To set up DevOps Guru with Quick Setup

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Quick Setup**.
3. On the **DevOps Guru** card, choose **Create**.

#### Tip

If you already have one or more configurations in your account, first choose the **Library** tab or the **Create** button in the **Configurations** section to view the cards.

4. In the **Configuration options** section, choose the AWS resource types you want to analyze and your notification preferences.

If you don't select the **Analyze all AWS resources in all the accounts in my organization** option, you can choose AWS resources to analyze later in the DevOps Guru console.

DevOps Guru analyzes different AWS resource types (such as Amazon Simple Storage Service (Amazon S3) buckets and Amazon Elastic Compute Cloud (Amazon EC2) instances), which are categorized into two pricing groups. You pay for the AWS resource hours analyzed, for each active resource. A resource is only active if it produces metrics, events, or log entries within an hour. The rate you're charged for a specific AWS resource type depends on the price group.

If you select the **Enable SNS notifications** option, an Amazon Simple Notification Service (Amazon SNS) topic is created in each AWS account in the organizational units (OUs) you target with your configuration. DevOps Guru uses the topic to notify you about important DevOps Guru events, such as the creation of a new insight. If you don't enable this option, you can add a topic later in the DevOps Guru console.

If you select the **Enable AWS Systems Manager OpsItems** option, operational work items (OpsItems) will be created for related Amazon EventBridge events and Amazon CloudWatch alarms.

5. In the **Schedule** section, choose how frequently you want Quick Setup to remediate changes made to resources that differ from your configuration. The **Default** option runs once. If

you don't want Quick Setup to remediate changes made to resources that differ from your configuration, choose **Disabled** under **Custom**.

6. In the **Targets** section, choose whether to allow DevOps Guru to analyze resources in some of your organizational units (OUs), or the account you're currently logged in to.

If you choose **Custom**, continue to step 8.

If you choose **Current account**, continue to step 9.

7. In the **Target OUs** and **Target Regions** sections, select the check boxes of the OUs and Regions where you want to use DevOps Guru.
8. Choose the Regions where you want to use DevOps Guru in the current account.
9. Choose **Create**.

## Deploy Distributor packages using Quick Setup

Distributor is a capability of AWS Systems Manager. A Distributor package is a collection of installable software or assets that can be deployed as a single entity. With Quick Setup, you can deploy a Distributor package in an AWS account and an AWS Region or across an organization in AWS Organizations. Currently, only the EC2Launch v2 agent, Amazon Elastic File System (Amazon EFS) utilities package and Amazon CloudWatch agent can be deployed with Quick Setup. For more information about Distributor, see [AWS Systems Manager Distributor](#).

To deploy Distributor packages, perform the following tasks in the AWS Systems Manager Quick Setup console.

### To deploy Distributor packages with Quick Setup

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Quick Setup**.
3. On the **Distributor** card, choose **Create**.

#### Tip

If you already have one or more configurations in your account, first choose the **Library** tab or the **Create** button in the **Configurations** section to view the cards.

4. In the **Configuration options** section, choose the package you want to deploy.

5. In the **Targets** section, choose whether to deploy the package to your entire organization, some of your organizational units (OUs), or the account you're currently logged in to.

If you choose **Entire organization**, continue to step 8.

If you choose **Custom**, continue to step 7.

6. In the **Target OUs** section, select the check boxes of the OUs and Regions you want to deploy the package to.
7. Choose **Create**.

## Stop and start EC2 instances automatically on a schedule using Quick Setup

With Quick Setup, a capability of AWS Systems Manager, you can configure Resource Scheduler to automate the starting and stopping of Amazon Elastic Compute Cloud (Amazon EC2) instances.

This Quick Setup configuration helps you reduce operational costs by starting and stopping instances according to the schedule that you specify. This capability helps you avoid incurring unnecessary costs for running instances when they're not needed. For example, you currently might leave your instances running constantly, even though they're only used 10 hours a day, 5 days a week. Instead, you can schedule your instances to stop every day after business hours. As a result, there would be 70 percent savings for those instances because the running time is reduced from 168 hours to 50 hours. There is no cost to use Quick Setup. However, costs can be incurred by the resources you set up and the usage limits with no fees for the services used to set up your configuration.

With Resource Scheduler, you can choose to automatically stop and start instances across multiple AWS Regions and AWS accounts according to a schedule you define. The Quick Setup configuration targets Amazon EC2 instances using the tag key and value that you specify. Only the instances with a tag matching the value that you specify in your configuration are stopped or started by Resource Scheduler.

An individual configuration supports scheduling up to 5,000 instances per Region. If your case requires more than 5,000 instances to be scheduled in a given Region, you must create multiple configurations. Tag your instances accordingly so each configuration is managing up to 5,000 instances. When creating multiple Resource Scheduler Quick Setup configurations, you must specify different tag key values. For example, one configuration can use the tag key "Env" with the value "Prod", while another uses "Env" and "Dev".

If you delete your configuration, instances are no longer stopped and started according to the previously defined schedule. In rare cases, instances might not successfully stop or start due to API operation failures.

Resource Scheduler starts the tagged instances only if they are in the stopped state. Similarly, instances are only stopped if they are in the running state. Resource Scheduler operates on an event driven model and only starts or stops instances at the times that you specify. For example, you create a schedule that starts instances at 9 AM. Resource Scheduler starts all instances associated with the tag you specify that are in the stopped state at 9 AM. If the instances are manually stopped at a later time, Resource Scheduler will not start them again to maintain the running state. Similarly, if an instance is started manually after it was stopped according to your schedule, Resource Scheduler will not stop the instance again.

If you create a schedule with a start time that is later than the stop time, Resource Scheduler assumes your instances run overnight. For example, you create a schedule that starts instances at 9 PM, and stops instances at 7 AM. Resource Scheduler starts all instances associated with the tag you specify that are in the stopped state at 9 PM, and stops them at 7 AM the following day. For overnight schedules, the start time applies to the days you select for your schedule. However, the stop time applies to the following day in your schedule.

To set up scheduling for Amazon EC2 instances, perform the following tasks in the AWS Systems Manager Quick Setup console.

### To set up instance scheduling with Quick Setup

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Quick Setup**.
3. On the **Resource Scheduler** card, choose **Create**.

#### Tip

If you already have one or more configurations in your account, first choose the **Library** tab or the **Create** button in the **Configurations** section to view the cards.

4. In the **Instance tag** section, specify the tag key and value applied to the instances you want to associate with your schedule.

5. In the **Schedule options** section, specify the time zone, days, and times you want to start and stop your instances.
6. In the **Targets** section, choose whether to set scheduling for a **Custom** group of organizational units (OUs), or the **Current account** you're signed in to:
  - **Custom** – In the **Target OUs** section, select the OUs where you want to set up scheduling. Next, in the **Target Regions** section, select the Regions where you want to set up scheduling.
  - **Current account** – Select **Current Region** or **Choose Regions**. If you selected **Choose Regions**, choose the **Target Regions** where you want to set up scheduling.
7. Verify the schedule information in the **Summary** section.
8. Choose **Create**.

## Configure AWS Resource Explorer using Quick Setup

With Quick Setup, a capability of AWS Systems Manager, you can quickly configure AWS Resource Explorer to search and discover resources in your AWS account or across an entire AWS organization. You can search for your resources using metadata like names, tags, and IDs. AWS Resource Explorer provides fast responses to your search queries by using *indexes*. Resource Explorer creates and maintains indexes using a variety of data sources to gather information about resources in your AWS account.

Quick Setup for Resource Explorer automates the index configuration process. For more information about AWS Resource Explorer, see [What is AWS Resource Explorer?](#) in the AWS Resource Explorer User Guide.

During Quick Setup, Resource Explorer does the following:

- Creates an index in every AWS Region in your AWS account.
- Updates the index in the Region you specify to be the aggregator index for the account.
- Creates a default view in the aggregator index Region. This view has no filters so it returns all resources found in the index.

### Minimum permissions

To perform the steps in the following procedure, you must have the following permissions:

- **Action:** `resource-explorer-2:*` – **Resource:** no specific resource (\*)

- **Action:** iam:CreateServiceLinkedRole – **Resource:** no specific resource (\*)

## To configure Resource Explorer

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Quick Setup**.
3. On the **Resource Explorer** card, choose **Create**.
4. In the **Aggregator Index Region** section, choose which Region you want to contain the **aggregator index**. You should select the Region that is appropriate for the geographic location for your users.
5. (Optional) Select the **Replace existing aggregator indexes in Regions other than the one selected above** check box.
6. In the **Targets** section, choose the target **organization** or specific **Organizational Units (OUs)** containing the resources you want to discover.
7. In the **Regions** section, choose which **Regions** to include in the configuration.
8. Review the configuration summary, and then choose **Create**.

On the **Resource Explorer** page, you can monitor the configuration status.

## Troubleshooting Quick Setup results

Use the following information to help you troubleshoot problems with Quick Setup, a capability of AWS Systems Manager. This topic includes specific tasks to resolve issues based on the type of Quick Setup issue.

### Issue: Failed deployment

A deployment fails if the CloudFormation stack set failed during creation. Use the following steps to investigate a deployment failure.

1. Navigate to the [AWS CloudFormation console](#).
2. Choose the stack created by your Quick Setup configuration. The **Stack name** includes QuickSetup followed by the type of configuration you chose, such as SSMHostMgmt.

**Note**

CloudFormation sometimes deletes failed stack deployments. If the stack isn't available in the **Stacks** table, choose **Deleted** from the filter list.

3. View the **Status** and **Status reason**. For more information about stack statuses, see [Stack status codes](#) in the *AWS CloudFormation User Guide*.
4. To understand the exact step that failed, view the **Events** tab and review each event's **Status**.
5. Review [Troubleshooting](#) in the *AWS CloudFormation User Guide*.
6. If you are unable to resolve the deployment failure using the CloudFormation troubleshooting steps, delete the configuration and reconfigure it.

**Issue: Failed association**

The **Configuration details** table on the **Configuration details** page of your configuration shows a **Configuration status** of **Failed** if any of the associations failed during set up. Use the following steps to troubleshoot a failed association.

1. In the **Configuration details** table, choose the failed configuration and then choose **View Details**.
2. Copy the **Association name**.
3. Navigate to **State Manager** and paste the association name into the search field.
4. Choose the association and choose the **Execution history** tab.
5. Under **Execution ID**, choose the association execution that failed.
6. The **Association execution targets** page lists all of the nodes where the association ran. Choose the **Output** button for an execution that failed to run.
7. In the **Output** page, choose **Step - Output** to view the error message for that step in the command execution. Each step can display a different error message. Review the error messages for all steps to help troubleshoot the issue.

If viewing the step output doesn't solve the problem, then you can try to recreate the association. To recreate the association, first delete the failing association in State Manager.

After deleting the association, edit the configuration and choose the option you deleted and choose **Update**.

**Note**

To investigate **Failed** associations for an **Organization** configuration, you must sign in to the account with the failed association and use the following failed association procedure, previously described. The **Association ID** isn't a hyperlink to the target account when viewing results from the management account.

### Issue: Drift status

When viewing a configuration's details page, you can view the drift status of each deployment. Configuration drift occurs whenever a user makes any change to a service or feature that conflicts with the selections made through Quick Setup. If an association has changed after the initial configuration, the table displays a warning icon that indicates the number of items that have drifted. You can determine what caused the drift by hovering over the icon.

When an association is deleted in State Manager, the related deployments display a drift warning. To fix this, edit the configuration and choose the option that was removed when the association was deleted. Choose **Update** and wait for the deployment to complete.

## AWS Systems Manager operations tools

Operations tools are a suite of capabilities that help you manage your AWS resources.

- [Incident Manager](#) helps you mitigate and recover from incidents affecting your applications hosted on AWS.
- [Explorer](#) is a customizable operations dashboard that reports information about your AWS resources. Explorer displays an aggregated view of operations data (OpsData) for your AWS accounts and across AWS Regions.
- [OpsCenter](#) provides a central location where operations engineers and IT professionals can view, investigate, and resolve operational work items (OpsItems) related to AWS resources.
- [Amazon CloudWatch dashboards hosted by Systems Manager](#) are customizable home pages in the CloudWatch console that you can use to monitor your resources across AWS Regions in a single view.

## Topics

- [AWS Systems Manager Incident Manager](#)
- [AWS Systems Manager Explorer](#)
- [AWS Systems Manager OpsCenter](#)
- [Using Amazon CloudWatch dashboards hosted by Systems Manager](#)

## AWS Systems Manager Incident Manager

Use Incident Manager, a capability of AWS Systems Manager, to manage incidents occurring in your AWS hosted applications. Incident Manager combines user engagements, escalation, runbooks, response plans, chat channels, and post-incident analysis to help your team triage incidents faster and return your applications to normal. To learn more about Incident Manager, see the [Incident Manager User Guide](#).

## AWS Systems Manager Explorer

AWS Systems Manager Explorer is a customizable operations dashboard that reports information about your AWS resources. Explorer displays an aggregated view of operations data (OpsData) for your AWS accounts and across AWS Regions. In Explorer, OpsData includes metadata about the managed nodes in your [hybrid and multicloud](#) environment. OpsData also includes information provided by other Systems Manager capabilities, including Patch Manager patch compliance and State Manager association compliance details. To further simplify how you access OpsData, Explorer displays information from supporting AWS services like AWS Config, AWS Trusted Advisor, AWS Compute Optimizer, and AWS Support (support cases).

To raise operational awareness, Explorer also displays operational work items (OpsItems). Explorer provides context about how OpsItems are distributed across your business units or applications, how they trend over time, and how they vary by category. You can group and filter information in Explorer to focus on items that are relevant to you and that require action. When you identify high priority issues, you can use Systems Manager OpsCenter to run Automation runbooks and quickly resolve those issues. To get started with Explorer, open the [Systems Manager console](#). In the navigation pane, choose **Explorer**.

The following image shows some of the individual report boxes, called *widgets*, which are available in Explorer.

## What are the features of Explorer?

Explorer includes the following features:

- **Customizable display of actionable information:** Explorer includes drag-and-drop widgets that automatically display actionable information about your AWS resources. Explorer displays information in two types of widgets.
  - **Informational widgets:** These widgets summarize data from Amazon EC2, Patch Manager, State Manager, and supporting AWS services like AWS Trusted Advisor, AWS Compute Optimizer, and AWS Support. These widgets provide important context to help you understand the state and operational risks of your AWS resources. Examples of informational widgets include **Instance count**, **Instance by AMI**, **Total noncompliant nodes** (patching), **Noncompliant associations**, and **Support Center cases**.
  - **OpsItem widgets:** A Systems Manager *OpsItem* is an operational work item that is related to one or more AWS resources. OpsItems are a feature of Systems Manager OpsCenter. OpsItems

might require DevOps engineers to investigate and potentially remediate an issue. Examples of possible OpsItems include high EC2 instance CPU utilization, detached Amazon Elastic Block Store (Amazon EBS) volumes, AWS CodeDeploy deployment failure, or Systems Manager Automation execution failure. Examples of OpsItem widgets include **Open OpsItem summary**, **OpsItem by status**, and **OpsItems over time**.

- **Filters:** Each widget offers the ability to filter information based on AWS account, AWS Region, and tag. Filters help you quickly refine the information displayed in Explorer.
- **Direct links to service screens:** To help you investigate issues with AWS resources, Explorer widgets contain direct links to related service screens. Filters applied to a widget remain in effect if you navigate to a related service screen.
- **Groups:** To help you understand the types of operational issues across your organization, some widgets allow you to group data based on account, Region, and tag.
- **Reporting tag keys:** When you set up Explorer, you can specify up to five tag keys. These keys help you group and filter data in Explorer. If a specified key matches a key on a resource that generates an OpsItem, then the key and value are included in the OpsItems.
- **Three modes of AWS account and AWS Region display:** Explorer includes the following display modes for OpsData and OpsItems in AWS accounts and AWS Regions:
  - *Single-account/single-Region:* This is the default view. This mode allows users to view data and OpsItems from their own account and the current Region.
  - *Single-account/multiple-Region:* This mode requires you to create one or more resource data syncs by using the Explorer **Settings** page. A resource data sync aggregates OpsData from one or more Regions. After you create a resource data sync, you can toggle which sync to use on the Explorer dashboard. You can then filter and group data based on Region.
  - *Multiple-account/multiple-Region:* This mode requires that your organization or company use [AWS Organizations](#) with **All features** turned on. After you configure AWS Organizations in your computing environment, you can aggregate all account data in a management account. You can then create resource data syncs so that you can filter and group data based on Region. For more information about Organizations **All features** mode, see [Enabling All Features in Your Organization](#).
- **Reporting:** You can export Explorer reports as comma separated value (.csv) files to an Amazon Simple Storage Service (Amazon S3) bucket. You receive an alert from Amazon Simple Notification Service (Amazon SNS) when an export is complete.

## How does Explorer relate to OpsCenter?

[Systems Manager OpsCenter](#) provides a central location where operations engineers and IT professionals view, investigate, and resolve OpsItems related to AWS resources. Explorer is a report hub where DevOps managers view aggregated summaries of their operations data, including OpsItems, across AWS Regions and accounts. Explorer helps users discover trends and patterns and, if necessary, quickly resolve issues using Systems Manager Automation runbooks.

OpsCenter setup is now integrated with Explorer Setup. If you already set up OpsCenter, then Explorer automatically displays operations data, including aggregated information about OpsItems. If you haven't set up OpsCenter, then you can use Explorer Setup to get started with both capabilities. For more information, see [Getting started with Systems Manager Explorer and OpsCenter](#).

## What is OpsData?

OpsData is any operations data that is displayed in the Systems Manager Explorer dashboard. Explorer retrieves OpsData from the following sources:

- **Amazon Elastic Compute Cloud (Amazon EC2)**

Data displayed in Explorer includes: total number of nodes, total number of managed and unmanaged nodes, and a count of nodes using a specific Amazon Machine Image (AMI).

- **Systems Manager OpsCenter**

Data displayed in Explorer includes: a count of OpsItems by status, a count of OpsItems by severity, a count of open OpsItems across groups and across 30-day time periods, and historical data of OpsItems over time.

- **Systems Manager Patch Manager**

Data displayed in Explorer includes a count of noncompliant and critical noncompliant nodes.

- **AWS Trusted Advisor**

Data displayed in Explorer includes: status of best practice checks for EC2 Reserved Instances in the areas of cost optimization, security, fault tolerance, performance, and service limits.

- **AWS Compute Optimizer**

Data displayed in Explorer includes: a count of **Under provisioned** and **Over provisioned** EC2 instances, optimization findings, on-demand pricing details, and recommendations for instance type and price.

- **AWS Support Center cases**

Data displayed in Explorer includes: case ID, severity, status, created time, subject, service, and category.

- **AWS Config**

Data displayed in Explorer includes: overall summary of compliant and non-compliant AWS Config rules, the number of compliant and non-compliant resources, and specific details about each (when you drill down into a non-compliant rule or resource).

- **AWS Security Hub**

Data displayed in Explorer includes: overall summary of Security Hub findings, the number of each finding grouped by severity, and specific details about finding.

 **Note**

To view AWS Trusted Advisor and AWS Support Center cases in Explorer, you must have either an Enterprise or Business account set up with AWS Support.

You can view and manage OpsData sources from the Explorer **Settings** page. For information about setting up and configuring services that populate Explorer widgets with OpsData, see [Setting up related services for Explorer](#).

## Is there a charge to use Explorer?

Yes. When you turn on the default rules for creating OpsItems during Integrated Setup, you initiate a process that automatically creates OpsItems. Your account is charged based on the number of OpsItems created per month. Your account is also charged based on the number of GetOpsItem, DescribeOpsItem, UpdateOpsItem, and GetOpsSummary API calls made per month. Additionally, you can be charged for public API calls to other services that expose relevant diagnostic information. For more information, see [AWS Systems Manager Pricing](#).

## Topics

- [Getting started with Systems Manager Explorer and OpsCenter](#)
- [Using Explorer](#)
- [Exporting OpsData from Systems Manager Explorer](#)
- [Troubleshooting Systems Manager Explorer](#)

## Getting started with Systems Manager Explorer and OpsCenter

AWS Systems Manager uses an integrated setup experience to help you get started with Systems Manager Explorer and Systems Manager OpsCenter. In this documentation, Explorer and OpsCenter Setup is called *Integrated Setup*. If you already set up OpsCenter, you still need to complete Integrated Setup to verify settings and options. If you haven't set up OpsCenter, then you can use Integrated Setup to get started with both capabilities.

### Note

Integrated Setup is only available in the Systems Manager console. You can't set up Explorer or OpsCenter programmatically.

Integrated Setup performs the following tasks:

- [Configures roles and permissions](#): Integrated Setup creates an AWS Identity and Access Management (IAM) role that allows Amazon EventBridge to automatically create OpsItems based on default rules. After setting up, you must configure user, group, or role permissions for OpsCenter, as described in this section.
- [Allows default rules for OpsItem creation](#): Integrated Setup creates default rules in EventBridge. These rules automatically create OpsItems in response to events. Examples of these events are: state change for an AWS resource, a change in security settings, or a service becoming unavailable.
- Activates OpsData sources: Integrated Setup activates the following data sources that populate Explorer widgets.
  - AWS Support Center (You must have either a Business or Enterprise Support plan to activate this source.)
  - AWS Compute Optimizer (You must have either a Business or Enterprise Support plan to activate this source.)
  - Systems Manager State Manager association compliance

- AWS Config Compliance
- Systems Manager OpsCenter
- Systems Manager Patch Manager patch compliance
- Amazon Elastic Compute Cloud (Amazon EC2)
- Systems Manager Inventory
- AWS Trusted Advisor (You must have either a Business or Enterprise Support plan to activate this source.)
- AWS Security Hub

### Note

You can change setup configurations at any time on the **Settings** page.

After you complete Integrated Setup, we recommend that you [Set up Explorer to display data from multiple Regions and accounts](#). Explorer and OpsCenter automatically synchronize OpsData and OpsItems for the AWS account and AWS Region you used when you completed Integrated Setup. You can aggregate OpsData and OpsItems from other accounts and Regions by creating a resource data sync.

### Setting up related services for Explorer

AWS Systems Manager Explorer and AWS Systems Manager OpsCenter collect information from, or interact with, other AWS services and Systems Manager capabilities. We recommend that you set up and configure these other services or capabilities before you use Integrated Setup.

The following table includes tasks that allow Explorer and OpsCenter to collect information from, or interact with, other AWS services and Systems Manager capabilities.

| Task   | Information   |
|--|---|
| Verify permissions in Systems Manager Automation | Explorer and OpsCenter allow you to remediate issues with AWS resources by using Systems Manager Automation runbooks. To use this remediation capability, you must have permission to run Systems Manager |

| Task   | Information  |
|--|--|
|  | Automation runbooks. For more information, see <a href="#">Setting up Automation</a> .   |
| Set up and configure Systems Manager Patch Manager | Explorer includes a widget that provides information about patch compliance. To view this data in Explorer, you must configure patching. For more information, see <a href="#">AWS Systems Manager Patch Manager</a> .   |
| Set up and configure Systems Manager State Manager | Explorer includes a widget that provides information about Systems Manager State Manager association compliance. To view this data in Explorer, you must configure State Manager. For more information, see <a href="#">AWS Systems Manager State Manager</a> .  |
| Turn on AWS Config Configuration Recorder          | <p>Explorer uses data provided by AWS Config configuration recorder to populate widgets with information about your EC2 instances. To view this data in Explorer, turn on AWS Config configuration recorder. For more information, see <a href="#">Managing the Configuration Recorder</a>.</p> <div data-bbox="829 1247 1507 1612"><p> <b>Note</b></p><p>After you allow configuration recorder, Systems Manager can take up to six hours to display data in Explorer widgets that display information about your EC2 instances.</p></div> |

| Task                          | Information  |
|-------------------------------|--|
| Turn on AWS Trusted Advisor   | Explorer uses data provided by Trusted Advisor to display a status of best practice checks for Amazon EC2 Reserved Instances in the areas of cost optimization, security, fault tolerance , performance, and service limits. To view this data in Explorer, you must have a business or enterprise support plan. For more information, see <a href="#">AWS Support</a> .                               |
| Turn on AWS Compute Optimizer | Explorer uses data provided by Compute Optimizer to display details a count of <b>Under provisioned</b> and <b>Over provisioned</b> EC2 instances, optimization findings, on-demand pricing details, and recommendations for instance type and price. To view this data in Explorer, turn on Compute Optimizer. For more information, see <a href="#">Getting started with AWS Compute Optimizer</a> . |
| Turn on AWS Security Hub      | Explorer uses data provided by Security Hub to populate widgets with information about your security findings. To view this data in Explorer, turn on Security Hub integration. For more information, see <a href="#">What is AWS Security Hub</a> .   |

## Configuring roles and permissions for Systems Manager Explorer

Integrated Setup automatically creates and configures AWS Identity and Access Management (IAM) roles for AWS Systems Manager Explorer and AWS Systems Manager OpsCenter. If you completed Integrated Setup, then you don't need to perform any additional tasks to configure roles and permissions for Explorer. However, you must configure permission for OpsCenter, as described later in this topic.

Integrated Setup creates and configures the following roles for working with Explorer and OpsCenter.

- `AWSServiceRoleForAmazonSSM`: Provides access to AWS resources managed or used by Systems Manager.
- `OpsItem-CWE-Role`: Allows CloudWatch Events and EventBridge to create OpsItems in response to common events.
- `AWSServiceRoleForAmazonSSM_AccountDiscovery`: Allows Systems Manager to call other AWS services to discover AWS account information when synchronizing data. For more information about this role, see [Using roles to collect AWS account information for OpsCenter and Explorer](#).
- `AmazonSSMExplorerExport`: Allows Explorer to export OpsData to a comma-separated value (CSV) file.

If you configure Explorer to display data from multiple accounts and Regions by using AWS Organizations and a resource data sync, then Systems Manager creates the `AWSServiceRoleForAmazonSSM_AccountDiscovery` service-linked role. Systems Manager uses this role to get information about your AWS accounts in AWS Organizations. The role uses the following permissions policy.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "organizations:DescribeAccount",
        "organizations:DescribeOrganization",
        "organizations:ListAccounts",
        "organizations:ListAWSServiceAccessForOrganization",
        "organizations:ListChildren",
        "organizations:ListParents"
      ],
      "Resource": "*"
    }
  ]
}
```

For more information about the `AWSServiceRoleForAmazonSSM_AccountDiscovery` role, see [Using roles to collect AWS account information for OpsCenter and Explorer](#).

## Configuring permissions for Systems Manager OpsCenter

After you complete Integrated Setup, you must configure user, group, or role permissions so that users can perform actions in OpsCenter.

### Before you begin

You can configure OpsCenter to create and manage OpsItems for a single account or across multiple accounts. If you configure OpsCenter to create and manage OpsItems across multiple accounts, you can use either the Systems Manager delegated administrator account or the AWS Organizations management account to manually create, view, or edit OpsItems in other accounts. For more information about the Systems Manager delegated administrator account, see [Configuring a delegated administrator for Explorer](#).

If you configure OpsCenter for a single account, you can only view or edit OpsItems in the account where OpsItems were created. You can't share or transfer OpsItems across AWS accounts. For this reason, we recommend that you configure permissions for OpsCenter in the AWS account that is used to run your AWS workloads. You can then create users or groups in that account. In this way, multiple operations engineers or IT professionals can create, view, and edit OpsItems in the same AWS account.

Explorer and OpsCenter use the following API operations. You can use all features of Explorer and OpsCenter if your user, group, or role has access to these actions. You can also create more restrictive access, as described later in this section.

- [CreateOpsItem](#)
- [CreateResourceDataSync](#)
- [DescribeOpsItems](#)
- [DeleteResourceDataSync](#)
- [GetOpsItem](#)
- [GetOpsSummary](#)
- [ListResourceDataSync](#)
- [UpdateOpsItem](#)
- [UpdateResourceDataSync](#)

If you prefer, you can specify read-only permission by adding the following inline policy to your account, group, or role.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ssm:GetOpsItem",
        "ssm:GetOpsSummary",
        "ssm:DescribeOpsItems",
        "ssm:GetServiceSetting",
        "ssm:ListResourceDataSync"
      ],
      "Resource": "*"
    }
  ]
}
```

For more information about creating and editing IAM policies, see [Creating IAM Policies](#) in the *IAM User Guide*. For information about how to assign this policy to an IAM group, see [Attaching a Policy to an IAM Group](#).

Create a permission using the following and add it to your users, groups, or roles:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ssm:GetOpsItem",
        "ssm:UpdateOpsItem",
        "ssm:DescribeOpsItems",
        "ssm:CreateOpsItem",
        "ssm:CreateResourceDataSync",
        "ssm>DeleteResourceDataSync",
        "ssm:ListResourceDataSync",
        "ssm:UpdateResourceDataSync"
      ],
      "Resource": "*"
    }
  ]
}
```

```
}
```

Depending on the identity application that you are using in your organization, you can select any of the following options to configure user access.

To provide access, add permissions to your users, groups, or roles:

- Users and groups in AWS IAM Identity Center:

Create a permission set. Follow the instructions in [Create a permission set](#) in the *AWS IAM Identity Center User Guide*.

- Users managed in IAM through an identity provider:

Create a role for identity federation. Follow the instructions in [Create a role for a third-party identity provider \(federation\)](#) in the *IAM User Guide*.

- IAM users:

- Create a role that your user can assume. Follow the instructions in [Create a role for an IAM user](#) in the *IAM User Guide*.
- (Not recommended) Attach a policy directly to a user or add a user to a user group. Follow the instructions in [Adding permissions to a user \(console\)](#) in the *IAM User Guide*.

## Restricting access to OpsItems by using tags

You can also restrict access to OpsItems by using an inline IAM policy that specifies tags. Here is an example that specifies a tag key of *Department* and a tag value of *Finance*. With this policy, the user can only call the *GetOpsItem* API operation to view OpsItems that were previously tagged with Key=Department and Value=Finance. Users can't view any other OpsItems.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ssm:GetOpsItem"
      ],
      "Resource": "*"
    },
    {
      "Condition": { "StringEquals": { "ssm:resourceTag/Department": "Finance" } }
    }
  ]
}
```

```
    }  
  ]  
}
```

Here is an example that specifies API operations for viewing and updating OpsItems. This policy also specifies two sets of tag key-value pairs: Department-Finance and Project-Unity.

```
{  
  "Version": "2012-10-17",  
  "Statement": [  
    {  
      "Effect": "Allow",  
      "Action": [  
        "ssm:GetOpsItem",  
        "ssm:UpdateOpsItem"  
      ],  
      "Resource": "*",  
      "Condition": {  
        "StringEquals": {  
          "ssm:resourceTag/Department": "Finance",  
          "ssm:resourceTag/Project": "Unity"  
        }  
      }  
    }  
  ]  
}
```

For information about adding tags to an OpsItem, see [Create OpsItems manually](#).

## Understanding default EventBridge rules created by Integrated Setup

During the integrated setup process for Explorer and OpsCenter, you can choose to enable a number of default rules that are based on events detected by Amazon EventBridge. When these events are detected, the system automatically creates OpsItems in AWS Systems Manager OpsCenter.

For example, the rule `SSMOpsItems-Autoscaling-instance-termination-failure` results in an OpsItem being created when the termination of an EC2 auto scaling instance fails.

The rule `SSMOpsItems-SSM-maintenance-window-execution-failed` results in an OpsItem being created when a Systems Manager maintenance window fails to complete successfully.

For setup instructions and descriptions of all the EventBridge rules you can enable during the setup process, see [Set up OpsCenter](#).

If you don't want EventBridge to create OpsItems for these events, you can choose not to enable this option in Integrated Setup. If you prefer, you can specify OpsCenter as the target of specific EventBridge events. For more information, see [Configure EventBridge rules to create OpsItems](#).

You can disable a default rule or change its category and severity level in the OpsCenter **Settings** page by choosing **OpsCenter, Settings**, and then choosing **Edit** in the **OpsItem rules** area.

You can also edit the category or severity assigned to an individual OpsItem created from these rules in the Systems Manager console. For information, see [Editing an OpsItem](#).

| OpsItem rules <span>Edit</span>                                       |              |          |           |
|---|--------------|----------|-----------|
| <input type="text"/>  |              |          |           |
| Rule  | Category     | Severity | State     |
| <a href="#">SSMOpsItems-Autoscaling-instance-launch-failure</a>       | Availability | 2-High   | ✔ enabled |
| <a href="#">SSMOpsItems-Autoscaling-instance-termination-failure</a>  | Availability | 2-High   | ✔ enabled |
| <a href="#">SSMOpsItems-EBS-snapshot-copy-failed</a>                  | Availability | 2-High   | ✔ enabled |
| <a href="#">SSMOpsItems-EBS-snapshot-creation-failed</a>              | Availability | 2-High   | ✔ enabled |
| <a href="#">SSMOpsItems-EBS-volume-performance-issue</a>              | Performance  | 3-Medium | ✔ enabled |
| <a href="#">SSMOpsItems-EC2-issue</a>                                 | Availability | 2-High   | ✔ enabled |
| <a href="#">SSMOpsItems-EC2-scheduled-change</a>                      | Availability | 3-Medium | ✔ enabled |
| <a href="#">SSMOpsItems-RDS-issue</a>                                 | Availability | 2-High   | ✔ enabled |
| <a href="#">SSMOpsItems-RDS-scheduled-change</a>                      | Availability | 3-Medium | ✔ enabled |
| <a href="#">SSMOpsItems-SSM-maintenance-window-execution-failed</a>   | Availability | 3-Medium | ✔ enabled |
| <a href="#">SSMOpsItems-SSM-maintenance-window-execution-timedout</a> | Availability | 2-High   | ✔ enabled |

## Configuring a delegated administrator for Explorer

If you aggregate AWS Systems Manager Explorer data from multiple AWS Regions and accounts by using resource data sync with AWS Organizations, then we recommend that you configure a delegated administrator for Explorer.

A delegated administrator can use the following Explorer resource data sync APIs using the console, SDK, AWS Command Line Interface (AWS CLI), or AWS Tools for Windows PowerShell:

- [CreateResourceDataSync](#)
- [DeleteResourceDataSync](#)
- [ListResourceDataSync](#)
- [UpdateResourceDataSync](#)

A delegated administrator can create a maximum of five resource data syncs for either an entire organization or a subset of organizational units. Resource data syncs created by a delegated administrator are only available in the delegated administrator account. You can't view the syncs or the aggregated data in the AWS Organizations management account.

For more information about resource data sync, see [Setting up Systems Manager Explorer to display data from multiple accounts and Regions](#). For more information about AWS Organizations, see [What is AWS Organizations?](#) in the *AWS Organizations User Guide*.

## Topics

- [Configure an Explorer delegated administrator](#)
- [Deregister an Explorer delegated administrator](#)

## Configure an Explorer delegated administrator

Use the following procedure to register an Explorer delegated administrator.

### To register an Explorer delegated administrator

1. Log into your AWS Organizations management account.
2. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
3. In the navigation pane, choose **Explorer**.
4. Choose **Settings**.
5. In the **Delegated administrator for Explorer** section, verify that you have configured the required service-linked role and service access options. If necessary, choose the **Create role** and **Enable access** buttons to configure these options.

6. For **Account ID**, enter the AWS account ID. This account must be a member account in AWS Organizations.
7. Choose **Register delegated administrator**.

The delegated administrator now has access to the **Include all accounts from my AWS Organizations configuration** and **Select organization units in AWS Organizations** options on the **Create resource data sync** page.

### Deregister an Explorer delegated administrator

Use the following procedure to deregister an Explorer delegated administrator. A delegated administrator account can only be deregistered by the AWS Organizations management account. When a delegated administrator account is deregistered, the system deletes all AWS Organizations resource data syncs created by the delegated administrator.

#### To deregister an Explorer delegated administrator

1. Log into your AWS Organizations management account.
2. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
3. In the navigation pane, choose **Explorer**.
4. Choose **Settings**.
5. In the **Delegated administrator for Explorer** section, choose **Deregister**. The system displays a warning.
6. Enter the account ID and choose **Remove**.

The account no longer has access to the AWS Organizations resource data sync API operations. The system deletes all AWS Organizations resource data syncs created by the account.

### Setting up Systems Manager Explorer to display data from multiple accounts and Regions

AWS Systems Manager uses an integrated setup experience to help you get started with AWS Systems Manager Explorer *and* AWS Systems Manager OpsCenter. After completing Integrated Setup, Explorer and OpsCenter automatically synchronize data. More specifically, these capabilities synchronize OpsData and OpsItems for the AWS account and AWS Region you used when you completed Integrated Setup. If you want to aggregate OpsData and OpsItems from other accounts and Regions, you must create a resource data sync, as described in this topic.

**Note**

For more information about Integrated Setup, see [Getting started with Systems Manager Explorer and OpsCenter](#).

**Topics**

- [Understanding resource data syncs for Explorer](#)
- [Understanding multiple account and Region resource data syncs](#)
- [Creating a resource data sync](#)

**Understanding resource data syncs for Explorer**

Resource data sync for Explorer offers two aggregation options:

- **Single-account/Multiple-regions:** You can configure Explorer to aggregate OpsItems and OpsData data from multiple AWS Regions, but the data set is limited to the current AWS account.
- **Multiple-accounts/Multiple-regions:** You can configure Explorer to aggregate data from multiple AWS Regions and accounts. This option requires that you set up and configure AWS Organizations. After you set up and configure AWS Organizations, you can aggregate data in Explorer by organizational unit (OU) or for an entire organization. Systems Manager aggregates the data into the AWS Organizations management account before displaying it in Explorer. For more information, see [What is AWS Organizations?](#) in the *AWS Organizations User Guide*.

**Warning**

If you configure Explorer to aggregate data from an organization in AWS Organizations, the system enables OpsData in all member accounts in the organization. Enabling OpsData sources in all member accounts increases the number of calls to OpsCenter APIs like [CreateOpsItem](#) and [GetOpsSummary](#). You are charged for calls to these API actions.

The following diagram shows a resource data sync configured to work with AWS Organizations. In this scenario, the user has two accounts defined in AWS Organizations. Resource data sync aggregates data from both accounts and multiple AWS Regions into the AWS Organizations management account where it's then displayed in Explorer.

## Understanding multiple account and Region resource data syncs

This section describes important details about multiple account and multiple Region resource data syncs that use AWS Organizations. Specifically, the information in this section applies if you choose one of the following options in the **Create resource data sync** page:

- Include all accounts from my AWS Organizations configuration
- Select organization units in AWS Organizations

If you don't plan to use one of these options, you can skip this section.

When you create a resource data sync in the SSM console, if you choose one of the AWS Organizations options, then Systems Manager automatically allows all OpsData sources in the selected Regions for all AWS accounts in your organization (or in the selected organizational

units). For example, even if you haven't turned Explorer on in a Region, if you select an AWS Organizations option for your resource data sync, then Systems Manager automatically collects OpsData from that Region. To create a resource data sync without allowing OpsData sources, specify **EnableAllOpsDataSources** as false when creating the data sync. For more information, see the `EnableAllOpsDataSources` parameter details for the [ResourceDataSyncSource](#) data type in the *Amazon EC2 Systems Manager API Reference*.

If you don't choose one of the AWS Organizations options for a resource data sync, then you must complete Integrated Setup in each account and Region where you want Explorer to access data. If you don't, Explorer won't display OpsData and OpsItems for those accounts and Regions in which you didn't complete Integrated Setup.

If you add a child account to your organization, Explorer automatically allows all OpsData sources for the account. If, at a later time, you remove the child account from your organization, Explorer continues to collect OpsData from the account.

If you update an existing resource data sync that uses one of the AWS Organizations options, the system prompts you to approve collection of all OpsData sources for all accounts and Regions affected by the change.

If you add a new service to your AWS account, and if Explorer collects OpsData for that service, Systems Manager automatically configures Explorer to collect that OpsData. For example, if your organization didn't use AWS Trusted Advisor when you previously created a resource data sync, but your organization signs up for this service, Explorer automatically updates your resource data syncs to collect this OpsData.

### Important

Note the following important information about multiple account and Region resource data syncs:

- Deleting a resource data sync doesn't turn off an OpsData source in Explorer.
- To view OpsData and OpsItems from multiple accounts, you must have the AWS Organizations **All features** mode turned on and you must be signed into the AWS Organizations management account.

## Creating a resource data sync

Before you configure a resource data sync for Explorer, note the following details.

- Explorer supports a maximum of five resource data syncs.
- After you create a resource data sync for a Region, you can't change the *account options* for that sync. For example, if you create a sync in the us-east-2 (Ohio) Region and you choose the **Include only the current account** option, you can't edit that sync later and choose the **Include all accounts from my AWS Organizations configuration** option. Instead, you must delete the first resource data sync, and create a new one.
- OpsData viewed in Explorer is read-only.

Use the following procedure to create a resource data sync for Explorer.

### To create a resource data sync

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Explorer**.
3. Choose **Settings**.
4. In the **Configure resource data sync** section, choose **Create resource data sync**.
5. For **Resource data sync name**, enter a name.
6. In the **Add accounts** section, choose an option.

#### Note

To use either of the AWS Organizations options, you must be logged into the AWS Organizations management account or you must be logged into an Explorer delegated administrator account. For more information about the delegated administrator account, see [Configuring a delegated administrator for Explorer](#).

7. In the **Regions to include** section, choose one of the following options.
  - Choose **All current and future regions** to automatically sync data from all current AWS Regions and any new Regions that come online in the future.
  - Choose **All regions** to automatically sync data from all current AWS Regions.
  - Individually choose Regions that you want to include.
8. Choose **Create resource data sync**.

The system can take several minutes to populate Explorer with data after you create a resource data sync. You can view the sync by choosing it from the **Select a resource data sync** list in Explorer.

## Using Explorer

This section includes information about how to customize AWS Systems Manager Explorer by changing the widget layout and by changing the data that displays in the dashboard.

### Contents

- [Editing EventBridge rules created for Explorer](#)
- [Editing Systems Manager Explorer data sources](#)
- [Customizing the Explorer display](#)
- [Receiving findings from AWS Security Hub in Explorer](#)
- [Deleting a Systems Manager Explorer resource data sync](#)

### Editing EventBridge rules created for Explorer

When you complete Integrated Setup, the system allows more than a dozen rules in Amazon EventBridge. These rules automatically create OpsItems in AWS Systems Manager OpsCenter. AWS Systems Manager Explorer then displays aggregated information about the OpsItems.

Each rule includes a preset **Category** and **Severity** value. When the system creates OpsItems from an event, it automatically assigns the preset **Category** and **Severity**.

#### Important

You can't edit the **Category** and **Severity** values for default rules but you can edit these values on OpsItems created from the default rules.

| OpsItem rules   |              |          |           |
|---|--------------|----------|-----------|
| <a href="#">Edit</a>  |              |          |           |
| <input type="text" value="Q"/>  |              |          |           |
| Rule  | Category     | Severity | State     |
| <a href="#">SSMOpsItems-Autoscaling-instance-launch-failure</a>       | Availability | 2-High   | ✔ enabled |
| <a href="#">SSMOpsItems-Autoscaling-instance-termination-failure</a>  | Availability | 2-High   | ✔ enabled |
| <a href="#">SSMOpsItems-EBS-snapshot-copy-failed</a>                  | Availability | 2-High   | ✔ enabled |
| <a href="#">SSMOpsItems-EBS-snapshot-creation-failed</a>              | Availability | 2-High   | ✔ enabled |
| <a href="#">SSMOpsItems-EBS-volume-performance-issue</a>              | Performance  | 3-Medium | ✔ enabled |
| <a href="#">SSMOpsItems-EC2-issue</a>                                 | Availability | 2-High   | ✔ enabled |
| <a href="#">SSMOpsItems-EC2-scheduled-change</a>                      | Availability | 3-Medium | ✔ enabled |
| <a href="#">SSMOpsItems-RDS-issue</a>                                 | Availability | 2-High   | ✔ enabled |
| <a href="#">SSMOpsItems-RDS-scheduled-change</a>                      | Availability | 3-Medium | ✔ enabled |
| <a href="#">SSMOpsItems-SSM-maintenance-window-execution-failed</a>   | Availability | 3-Medium | ✔ enabled |
| <a href="#">SSMOpsItems-SSM-maintenance-window-execution-timedout</a> | Availability | 2-High   | ✔ enabled |

## To edit default rules for creating OpsItems

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Explorer**.
3. Choose **Settings**.
4. In the **OpsItems rules** section, choose **Edit**.
5. Expand **CWE rules**.
6. Clear the check box beside those rules that you don't want to use.
7. Use the **Category** and **Severity** lists to change this information for a rule.
8. Choose **Save**.

Your changes take effect the next time the system creates an OpsItem.

## Editing Systems Manager Explorer data sources

AWS Systems Manager Explorer displays data from the following sources. You can edit Explorer settings to add or remove data sources:

- Amazon Elastic Compute Cloud (Amazon EC2)
- AWS Systems Manager OpsCenter
- AWS Systems Manager Patch Manager patch compliance
- AWS Systems Manager State Manager association compliance
- AWS Trusted Advisor
- AWS Compute Optimizer
- AWS Support Center cases
- AWS Config rule and resource compliance
- AWS Security Hub findings

### Note

- To view AWS Support Center cases in Explorer, you must have either an Enterprise or Business account set up with AWS Support.
- You can't configure Explorer to stop displaying OpsCenter OpsItem data.

## Before you begin

Verify that you set up and configured services that populate Explorer widgets with data. For more information, see [Setting up related services for Explorer](#).

## To edit data sources

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Explorer**.
3. Choose **Settings**, and then choose the **Configure Dashboard** tab.
4. In the **OpsData sources** section, in the **Status** column, turn on or turn off sources according to the data you want to view.

## Customizing the Explorer display

You can customize widget layout in AWS Systems Manager Explorer by using a drag-and-drop capability. You can also customize the OpsData and OpsItems displayed in Explorer by using filters, as described in this topic.

Before you customize widget layout, verify that the widgets you want to view are currently displayed in Explorer. To view some widgets in Explorer (such as the AWS Config compliance widget), you must enable them on the **Configure dashboard** page.

### To enable widgets to display in Explorer

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Explorer**.
3. Choose **Dashboard actions, Configure dashboard**.
4. Choose the **Configure Dashboard** tab.
5. Either choose **Enable all** or turn on an individual widget or data source.
6. Choose **Explorer** to view your changes.

To customize widget layout in Explorer, choose a widget that you want to move. Click and hold the name of the widget and then drag it to its new location.

The screenshot displays two widgets from the AWS Systems Manager Explorer console. The 'Open OpsItem summary' widget is a table with columns for 'Groups', 'Total', '0-30 days', '31-60 days', and '61+ days'. The 'OpsItem by severity' widget is a bar chart showing counts for 'Critical', 'High', 'Medium', and 'Low' severity levels. Both widgets include a 'Last Update Time: seconds ago' indicator.

| Groups | Total | 0-30 days | 31-60 days | 61+ days |
|--------|-------|-----------|------------|----------|
| EC2    | 12    | 7         | 2          | 3        |
| SSM    | 1     | 1         | 0          | 0        |

OpsItem by severity

- 0 Critical
- 0 High
- 1 Medium
- 2 Low

14 Unresolved, 15 Open, 1 InProgress

Repeat this process for each widget that you want to reposition.

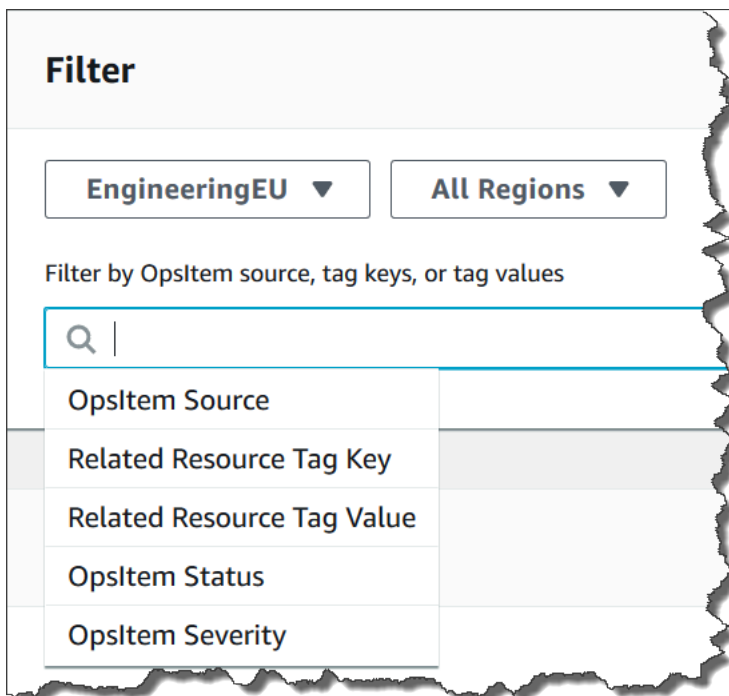

If you decide that you don't like the new layout, choose **Reset layout** to move all widgets back to their original location.

## Using filters to change the data displayed in Explorer

By default, Explorer displays data for the current AWS account and the current Region. If you create one or more resource data syncs, you can use filters to change which sync is active. You can then choose to display data for a specific Region or all Regions. You can also use the Search bar to filter on different OpsItem and key-tag criteria.

### To change the data displayed in Explorer by using filters

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Explorer**.
3. In the **Filter** section, use the **Select a resource data sync** list to choose a sync.
4. Use the **Regions** list to choose either a specific AWS Region or choose **All Regions**.
5. Choose the Search bar, and then choose the criteria on which to filter the data.

6. Press Enter.

Explorer retains the filter options you selected if you close and reopen the page.

## Receiving findings from AWS Security Hub in Explorer

[AWS Security Hub](#) provides a comprehensive view of your security state in AWS. The service collects security data, called *findings*, from across AWS accounts, services, and supported third-party products. Security Hub findings can help you check your environment against security industry standards and best practices, analyze your security trends, and identify the highest priority security issues.

Security Hub sends findings to Amazon EventBridge, which uses an event rule to send the findings to Explorer. After you enable integration, as described here, you can view Security Hub findings in an Explorer widget and view finding details in OpsCenter OpsItems. The widget provides a summary of all Security Hub findings based on severity. New findings in Security Hub are usually visible in Explorer within seconds of being created.

### Warning

Note the following important information:

- Explorer is integrated with OpsCenter, a capability of Systems Manager. After you enable Explorer integration with Security Hub, OpsCenter automatically creates OpsItems for Security Hub findings. Depending on your AWS environment, enabling integration can result in large numbers of OpsItems, at a cost.

Before you continue, read about OpsCenter integration with Security Hub. The topic includes specific details about how changes and updates to findings and OpsItems are charged to your account. For more information, see [Understanding OpsCenter integration with AWS Security Hub](#). For OpsCenter pricing information, see [AWS Systems Manager Pricing](#).

- If you create a resource data sync in Explorer while logged into the administrator account, Security Hub integration is automatically enabled for the administrator and all member accounts in the sync. Once enabled, OpsCenter automatically creates OpsItems for Security Hub findings, at a cost. For more information about creating a resource data sync, see [Setting up Systems Manager Explorer to display data from multiple accounts and Regions](#).

## Types of findings that Explorer receives

Explorer receives [all findings](#) from Security Hub. You can see all findings based on severity in the Explorer widget when you turn on the Security Hub default settings. By default, Explorer creates OpsItems for critical and high severity findings. You can manually configure Explorer to create OpsItems for medium and low severity findings.

Though Explorer doesn't create OpsItems for informational findings, you can view informational operations data (OpsData) in the Security Hub findings summary widget. Explorer creates OpsData for all findings regardless of severity. For more information about Security Hub severity levels, see [Severity](#) in the *AWS Security Hub API Reference*.

## Enabling integration

This section describes how to enable and configure Explorer to start receiving Security Hub findings.

### Before you begin

Complete the following tasks before you configure Explorer to start receiving Security Hub findings.

- Enable and configure Security Hub. For more information, see [Setting up Security Hub](#) in the *AWS Security Hub User Guide*.
- Log into the AWS Organizations management account. Systems Manager requires access to AWS Organizations to create OpsItems from Security Hub findings. After you log in to the management account, you're prompted to select the **Enable access** button on the Explorer **Configure dashboard** tab, as described in the following procedure. If you don't log in to the AWS Organizations management account, you can't allow access and Explorer can't create OpsItems from Security Hub findings.

### To start receiving Security Hub findings

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Explorer**.
3. Select **Settings**.
4. Select the **Configure dashboard** tab.

5. Select **AWS Security Hub**.
6. Select the **Disabled** slider to turn on **AWS Security Hub**.

Critical and high severity findings are displayed by default. To display medium and low severity findings, select the **Disabled** slider next to **Medium,Low**.

7. In the **OpsItems created by Security Hub findings** section, choose **Enable access**. If you don't see this button, log in to the AWS Organizations management account and return to this page to select the button.

## How to view findings from Security Hub

The following procedure describes how to view Security Hub findings.

### To view Security Hub findings

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Explorer**.
3. Find the **AWS Security Hub findings summary** widget. This displays your Security Hub findings. You can select a severity level to view a detailed description of the corresponding OpsItem.

## How to stop receiving findings

The following procedure describes how to stop receiving Security Hub findings.

### To stop receiving Security Hub findings

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Explorer**.
3. Select **Settings**.
4. Select the **Configure dashboard** tab.
5. Select the **Enabled** slider to turn off **AWS Security Hub**.

### Important

If the option to disable Security Hub findings is grayed out in the console, you can disable this setting by running the following command in the AWS CLI. You must run the command while logged into either the AWS Organizations management account or the Systems Manager delegated administrator account. For the `region` parameter, specify the AWS Region where you want to stop receiving Security Hub findings in Explorer.

```
aws ssm update-service-setting --setting-id /ssm/opsdata/SecurityHub --setting-value Disabled --region AWS Region
```

Here's an example.

```
aws ssm update-service-setting --setting-id /ssm/opsdata/SecurityHub --setting-value Disabled --region us-east-1
```

## Deleting a Systems Manager Explorer resource data sync

In AWS Systems Manager Explorer, you can aggregate OpsData and OpsItems from other accounts and Regions by creating a resource data sync.

You can't change the account options for a resource data sync. For example, if you created a sync in the us-east-2 (Ohio) Region and you chose the **Include only the current account** option, you can't edit that sync later and choose the **Include all accounts from my AWS Organizations configuration** option. Instead, you must delete the resource data sync, and create a new one, as described in the following procedure.

### To delete a resource data sync

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Explorer**.
3. Choose **Settings**.
4. In the **Configure resource data sync** section, choose the resource data sync that you want to delete.

## 5. Choose **Delete**.

## Exporting OpsData from Systems Manager Explorer

You can export 5,000 OpsData items as a comma separated value (.csv) file to an Amazon Simple Storage Service (Amazon S3) bucket from AWS Systems Manager Explorer. Explorer uses the [AWS-ExportOpsDataToS3](#) automation runbook to export OpsData. When you export OpsData, the system displays the automation runbook page where you can specify details, such as assumeRole, Amazon S3 bucket name, SNS topic ARN, and fields to be exported.

### To export OpsData:

- [Step 1: Specifying an SNS topic](#)
- [Step 2: \(Optional\) Configuring data export](#)
- [Step 3: Exporting OpsData](#)

### Step 1: Specifying an SNS topic

When you configure data export, you must specify an Amazon Simple Notification Service (Amazon SNS) topic that exists in the same AWS Region where you want to export the data. Systems Manager sends a notification to the Amazon SNS topic when an export is complete. For information about creating an Amazon SNS topic, see [Creating an Amazon SNS topic](#).

### Step 2: (Optional) Configuring data export

You can configure data export settings from the **Settings** or **Export Ops Data to S3 Bucket** page.

### To configure data export from Explorer

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Explorer**.
3. Choose **Settings**.
4. In the **Configure data export** section, choose **Edit**.
5. To upload the data export file to an existing Amazon S3 bucket, choose **Select an existing S3 bucket** and choose the bucket from the list.

To upload the data export file to a new Amazon S3 bucket, choose **Create a new S3 bucket** and enter the name that you want to use for the new bucket.

**Note**

You can only edit the Amazon S3 bucket name and Amazon SNS topic ARN from the page where you configured those settings for the first time in Explorer. If you set up the Amazon S3 bucket and the Amazon SNS topic ARN from the **Settings** page, then you can only modify those settings from the **Settings** page.

6. For **Select an Amazon SNS topic ARN**, choose the topic that you want to notify when the export is complete.
7. Choose **Create**.

### Step 3: Exporting OpsData

When you export Explorer data, Systems Manager creates an AWS Identity and Access Management (IAM) role named `AmazonSSMExplorerExportRole`. This role uses the following IAM policy.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "OpsSummaryExportAutomationServiceRoleStatement1",
      "Effect": "Allow",
      "Action": [
        "s3:PutObject"
      ],
      "Resource": [
        "arn:aws:s3:::{{ExportDestinationS3BucketName}}/*"
      ]
    },
    {
      "Sid": "OpsSummaryExportAutomationServiceRoleStatement2",
      "Effect": "Allow",
      "Action": [
        "s3:GetBucketAcl",
        "s3:GetBucketLocation"
      ],
      "Resource": [
```

```
        "arn:aws:s3:::{{ExportDestinationS3BucketName}}"
    ]
},
{
    "Sid": "OpsSummaryExportAutomationServiceRoleStatement3",
    "Effect": "Allow",
    "Action": [
        "sns:Publish"
    ],
    "Resource": [
        "{{SnsTopicArn}}"
    ]
},
{
    "Sid": "OpsSummaryExportAutomationServiceRoleStatement4",
    "Effect": "Allow",
    "Action": [
        "logs:DescribeLogGroups",
        "logs:DescribeLogStreams"
    ],
    "Resource": [
        "*"
    ]
},
{
    "Sid": "OpsSummaryExportAutomationServiceRoleStatement5",
    "Effect": "Allow",
    "Action": [
        "logs:CreateLogGroup",
        "logs:PutLogEvents",
        "logs:CreateLogStream"
    ],
    "Resource": [
        "*"
    ]
},
{
    "Sid": "OpsSummaryExportAutomationServiceRoleStatement6",
    "Effect": "Allow",
    "Action": [
        "ssm:GetOpsSummary"
    ],
    "Resource": [
        "*"
    ]
}
```

```

    ]
  }
]
}

```

The role includes the following trust entity.

```

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "OpsSummaryExportAutomationServiceRoleTrustPolicy",
      "Effect": "Allow",
      "Principal": {
        "Service": "ssm.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}

```

## To export OpsData from Explorer

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Explorer**.
3. Choose the link for a detailed view, such as the number of unresolved or open issues in **OpsItems by status** widget or the number of non-compliant resources in the **Desired state compliance status** widget.
4. Choose **Export Table**.

### Note

When you export OpsData for the first time, the system creates an assume role for the export. You can't modify the default assume role.

5. For **S3 Bucket Name**, choose an existing bucket. You can choose **Create** to create an Amazon S3 bucket if needed.

If you can't change the S3 bucket name, it means that you configured the bucket name from the **Settings** page. You can only change the bucket name from the **Settings** page.

 **Note**

You can only edit the Amazon S3 bucket name and Amazon SNS topic ARN from the page where you configured those settings for the first time in Explorer.

6. For **SNS Topic Arn**, choose an existing Amazon SNS topic ARN to notify when the download completes.

If you can't change the Amazon SNS topic ARN, it means that you configured the Amazon SNS topic ARN from the **Settings** page. You can only change the topic ARN from the **Settings** page.

7. (Optional) For **SNS Success Message**, specify a success message that you want to display when the export is successfully completed.
8. Choose **Submit**. The system navigates to the previous page and displays the message **Click to view status of export process. View details**.

You can choose **View details** to view the status of the runbook and progress in Systems Manager Automation.

You can now export OpsData from Explorer to the specified Amazon S3 bucket.

If you can't export data by using this procedure, verify that your user, group, or role includes the `iam:CreatePolicyVersion` and `iam>DeletePolicyVersion` actions. For information about adding these actions to your user, group, or role, see [Editing IAM policies](#) in the *IAM User Guide*.

## Troubleshooting Systems Manager Explorer

This topic includes information about how to troubleshoot common problems with AWS Systems Manager Explorer.

### Not able to filter AWS resources in Explorer after updating tags on the Settings page

If you update tags keys or other data settings in Explorer, the system can take up to six hours to synchronize data based on your changes.

### The AWS Organizations options on the *Create resource data sync* page are greyed out

The **Include all accounts from my AWS Organizations configuration** and **Select organization units in AWS Organizations** options on the **Create resource data sync** page are only available if you set up and configured AWS Organizations. If you set up and configured AWS Organizations, then either the AWS Organizations management account or an Explorer delegated administrator can create resource data syncs that use these options.

For more information, see [Setting up Systems Manager Explorer to display data from multiple accounts and Regions](#) and [Configuring a delegated administrator for Explorer](#).

### Explorer doesn't display any data at all

- Verify that you completed Integrated Setup in each account and Region where you want Explorer to access and display data. If you don't, Explorer won't display OpsData and OpsItems for those accounts and Regions in which you didn't complete Integrated Setup. For more information, see [Getting started with Systems Manager Explorer and OpsCenter](#).
- When using Explorer to view data from multiple accounts and Regions, verify that you're logged into the AWS Organizations management account or the Explorer delegated administrator account. To view OpsData and OpsItems from multiple accounts and Regions, you must be signed in to this account.

### Widgets about Amazon EC2 instances don't display data

If widgets about Amazon Elastic Compute Cloud (Amazon EC2) instances, such as the **Instance count**, **Managed instances**, and **Instance by AMI** widgets don't display data, then verify the following:

- Verify that you waited several minutes. OpsData can take several minutes to display in Explorer after you completed Integrated Setup.
- Verify that you configured AWS Config configuration recorder. Explorer uses data provided by AWS Config configuration recorder to populate widgets with information about your EC2 instances. For more information, see [Managing the Configuration Recorder](#).
- Verify that the **Amazon EC2** OpsData source is active on the **Settings** page. Also, verify that more than 6 hours have passed since you activated configuration recorder or since you made changes to your instances. Systems Manager can take up to six hours to display data from AWS Config in Explorer EC2 widgets after you initially activated configuration recorder or make changes to your instances.

- Be aware that if an instance is either stopped or terminated, then Explorer stops showing those instances after 24 hours.
- Verify that you're in the correct AWS Region where you configured your Amazon EC2 instances. Explorer doesn't display data about on-premises instances.
- If you configured a resource data sync for multiple accounts and Regions, verify that you're signed in to the Organizations management account or the Explorer delegated administrator account.

## Patch widget doesn't display data

The **Non-compliant instances for patching** widget only displays data about patch instances that aren't compliant. This widget displays no data if your instances are compliant. If you suspect that you have non-compliant instances, then verify that you set up and configured Systems Manager patching and use AWS Systems Manager Patch Manager to check your patch compliance. For more information, see [AWS Systems Manager Patch Manager](#).

## Miscellaneous issues

**Explorer doesn't let you edit or remediate OpsItems:** OpsItems viewed across accounts or Regions are read-only. They can only be updated and remediated from their home account or Region.

## AWS Systems Manager OpsCenter

OpsCenter, a capability of AWS Systems Manager, provides a central location where operations engineers and IT professionals can view, investigate, and resolve operational work items (OpsItems) related to AWS resources. OpsCenter is designed to reduce mean time to resolution for issues impacting AWS resources. OpsCenter aggregates and standardizes OpsItems across services while providing contextual investigation data about each OpsItem, related OpsItems, and related resources. OpsCenter also provides Systems Manager Automation runbooks that you can use to quickly resolve issues. You can specify searchable, custom data for each OpsItem. You can also view automatically-generated summary reports about OpsItems by status and source. To get started with OpsCenter, open the [Systems Manager console](#). In the navigation pane, choose **OpsCenter**.

OpsCenter is integrated with Amazon EventBridge and Amazon CloudWatch. This means you can configure these services to automatically create an OpsItem in OpsCenter when a CloudWatch alarm enters the ALARM state or when EventBridge processes an event from any AWS service that publishes events. Configuring CloudWatch alarms and EventBridge events to automatically create

OpsItems allows you to quickly diagnose and remediate issues with AWS resources from a single console.

To help you diagnose issues, each OpsItem includes contextually relevant information such as the name and ID of the AWS resource that generated the OpsItem, alarm or event details, alarm history, and an alarm timeline graph.

For the AWS resource, OpsCenter aggregates information from AWS Config, AWS CloudTrail logs, and Amazon CloudWatch Events, so you don't have to navigate across multiple console pages during your investigation.

The following list includes types of AWS resources and metrics for which customers configure CloudWatch alarms that create OpsItems.

- Amazon DynamoDB: database read and write actions reach a threshold
- Amazon EC2: CPU utilization reaches a threshold
- AWS billing: estimated charges reach a threshold
- Amazon EC2: an instance fails a status check
- Amazon Elastic Block Store (EBS): disk space utilization reaches a threshold

The following list includes types of EventBridge rules customer configure to create OpsItems.

- AWS Security Hub: security alert issued
- DynamoDB: a throttling event
- Amazon EC2 Auto Scaling: failure to launch an instance
- Systems Manager: failure to run an automation
- AWS Health: an alert for scheduled maintenance
- EC2: instance state change from Running to Stopped

OpsCenter is also integrated with Amazon CloudWatch Application Insights for .NET and SQL Server. This means you can automatically create OpsItems for problems detected in your applications. You can also integrate OpsCenter with AWS Security Hub to aggregate and take action on your security, performance, and operational issues in Systems Manager.

Operations engineers and IT professionals can create, view, and edit OpsItems by using the OpsCenter page in the AWS Systems Manager console, public API operations, the AWS Command

Line Interface (AWS CLI), AWS Tools for Windows PowerShell, or the AWS SDKs. OpsCenter public API operations also allows you to integrate OpsCenter with your case management systems and health dashboards.

## How can OpsCenter benefit my organization?

OpsCenter provides a standard and unified experience for viewing, working on, and remediating issues related to AWS resources. A standard and unified experience improves the time it takes to remedy issues, investigate related issues, and train new operations engineers and IT professionals. A standard and unified experience also reduces the number of manual errors entered into the system of managing and remediating issues.

More specifically, OpsCenter offers the following benefits for operations engineers and organizations:

- You no longer need to navigate across multiple console pages to view, investigate, and resolve OpsItems related to AWS resources. OpsItems are aggregated, across services, in a central location.
- You can view service-specific and contextually relevant data for OpsItems that are automatically generated by CloudWatch alarms, EventBridge events, and CloudWatch Application Insights for .NET and SQL Server.
- You can specify the Amazon Resource Name (ARN) of a resource related to an OpsItem. By specifying related resources, OpsCenter uses built-in logic to help you avoid creating duplicate OpsItems.
- You can view details and resolution information about similar OpsItems.
- You can quickly view information about and run Systems Manager Automation runbooks to resolve issues.

## What are the features of OpsCenter?

- **Automated and manual OpsItem creation**

OpsCenter is integrated with Amazon CloudWatch. This means you can configure CloudWatch to automatically create an OpsItem in OpsCenter when an alarm enters the ALARM state or when Amazon EventBridge processes an event from any AWS service that publishes events. You can also manually create OpsItems.

OpsCenter is also integrated with Amazon CloudWatch Application Insights for .NET and SQL Server. This means you can automatically create OpsItems for problems detected in your applications.

- **Detailed and searchable OpsItems**

Each OpsItem includes multiple fields of information, including a title, ID, priority, description, the source of the OpsItem, and the date/time it was last updated. Each OpsItem also includes the following configurable features:

- **Status:** Open, In progress, Resolved, or Open and In progress.
- **Related resources:** A related resource is the impacted resource or the resource that initiated the EventBridge event that created the OpsItem. Each OpsItem includes a **Related resources** section where OpsCenter automatically lists the Amazon Resource Name (ARN) of the related resource. You can also manually specify ARNs of related resources. For some ARN types, OpsCenter automatically creates a deep link that displays details about the resource without having to visit other console pages to view that information. For example, if you specify the ARN of an EC2 instance, you can view all of the EC2-provided details about that instance in OpsCenter. You can manually add the ARNs of additional related resources. Each OpsItem can list a maximum of 100 related resource ARNs. For more information, see [Adding related resources to an OpsItem](#).
- **Related and Similar OpsItems:** With the **Related OpsItems** feature, you can specify the IDs of OpsItems that are in some way related to the current OpsItem. The **Similar OpsItem** feature automatically reviews OpsItem titles and descriptions and then lists other OpsItems that might be related or of interest to you.
- **Searchable and private operational data:** Operational data is custom data that provides useful reference details about the OpsItem. For example, you can specify log files, error strings, license keys, troubleshooting tips, or other relevant data. You enter operational data as key-value pairs. The key has a maximum length of 128 characters. The value has a maximum size of 20 KB.

This custom data is searchable, but with restrictions. For the **Searchable operational data** feature, all users with access to the OpsItem Overview page (as provided by the [DescribeOpsItems](#) API operation) can view and search on the specified data. For the **Private operational data** feature, the data is only viewable by users who have access to the OpsItem (as provided by the [GetOpsItem](#) API operation).

- **Deduplication:** By specifying related resources, OpsCenter uses built-in logic to help you avoid creating duplicate OpsItems. OpsCenter also includes a feature called **Operational insights**, which displays information about duplicate OpsItems. To further limit the number of duplicate OpsItems in your account, you can manually specify a deduplication string for an EventBridge event rule. For more information, see [Managing duplicate OpsItems](#).
- **Bulk edit OpsItems:** You can select multiple OpsItems in OpsCenter and edit one of the following fields: **Status, Priority, Severity, Category**.
- **Easy remediation using runbooks**

Each OpsItem includes a **Runbooks** section with a list of Systems Manager Automation runbooks that you can use to automatically remediate common issues with AWS resources. If you open an OpsItem, choose an AWS resource for that OpsItem, and then choose the **Run automation** button in the console, then OpsCenter provides a list of Automation runbooks that you can run on the AWS resource that generated the OpsItem. After you run an Automation runbook from an OpsItem, the runbook is automatically associated with the related resource of the OpsItem for future reference. Additionally, if you automatically set up OpsItem rules in EventBridge by using OpsCenter, then EventBridge automatically associates runbooks for common events. OpsCenter keeps a 30-day record of Automation runbooks run for a specific OpsItem. For more information, see [Remediate OpsItem issues](#).

- **Change notification:** You can specify the ARN of an Amazon Simple Notification Service (SNS) topic and publish notifications anytime an OpsItem is changed or edited. The SNS topic must exist in the same AWS Region as the OpsItem.
- **Comprehensive OpsItem search capabilities:** OpsCenter provides multiple search options to help you quickly locate OpsItems. Here are several examples of how you can search: OpsItem ID, Title, Last modified time, Operational data value, Source, and Automation ID of a runbook execution, to name a few. You can further limit search results by using status filters.
- **OpsItem summary reports**

OpsCenter includes a summary report page that automatically displays the following sections:

- **Status summary:** a summary of OpsItems by status (Open, In progress, Resolved, Open and In progress).
- **Sources with most open OpsItems:** a breakdown of the top AWS services with open OpsItems.
- **OpsItems by source and age:** a count of OpsItems grouped by source and days since creation.

For more information about viewing OpsCenter summary reports, see [Viewing OpsCenter summary reports](#).

- **Logging and auditing capability support**

You can audit and log OpsCenter user actions in your AWS account through integration with other AWS services. For more information, see [Viewing OpsCenter logs and reports](#).

- **Console, CLI, PowerShell, and SDK access to OpsCenter capabilities**

You can work with OpsCenter by using the AWS Systems Manager console, AWS Command Line Interface (AWS CLI), AWS Tools for PowerShell, or the AWS SDK of your choice.

## **Does OpsCenter integrate with my existing case management system?**

OpsCenter is designed to complement your existing case management systems. You can integrate OpsItems into your existing case management system by using public API operations. You can also maintain manual lifecycle workflows in your current systems and use OpsCenter as an investigation and remediation hub.

For information about OpsCenter public API operations, see the following API operations in the *AWS Systems Manager API Reference*.

- [CreateOpsItem](#)
- [DescribeOpsItems](#)
- [GetOpsItem](#)
- [GetOpsSummary](#)
- [UpdateOpsItem](#)

## **Is there a charge to use OpsCenter?**

Yes. For more information, see [AWS Systems Manager Pricing](#).

## **Does OpsCenter work with my on-premises and hybrid managed nodes?**

Yes. You can use OpsCenter to investigate and remediate issues with your on-premises managed nodes that are configured for Systems Manager. For more information about setting up and configuring on-premises servers and virtual machines for Systems Manager, see [Managing nodes in hybrid and multicloud environments with Systems Manager](#).

## What are the quotas for OpsCenter?

You can view quotas for all Systems Manager capabilities in the [Systems Manager service quotas](#) in the *Amazon Web Services General Reference*. Unless otherwise noted, each quota is Region-specific.

## Set up OpsCenter

AWS Systems Manager uses an integrated setup experience to help you get started with OpsCenter and Explorer, which are capabilities of Systems Manager. Explorer is a customizable operations dashboard that reports information about your AWS resources. In this documentation, Explorer and OpsCenter setup is called *Integrated Setup*.

You must use Integrated Setup to set up OpsCenter with Explorer. Integrated Setup is only available in the AWS Systems Manager console. You can't set up Explorer and OpsCenter programmatically. For more information, see [Getting started with Systems Manager Explorer and OpsCenter](#).

### Before you begin

When you set up OpsCenter, you enable default rules in Amazon EventBridge that automatically create OpsItems. The following table describes the default EventBridge rules that automatically create OpsItems. You can disable EventBridge rules in the OpsCenter **Settings** page under **OpsItem rules**.

#### Important

Your account is charged for OpsItems created by default rules. For more information, see [AWS Systems Manager Pricing](#).

| Rule name  | Description   |
|--|---|
| SSMOpsItems-Autoscaling-instance-launch-failure      | This rule creates OpsItems when the launch of an EC2 auto scaling instance failed.      |
| SSMOpsItems-Autoscaling-instance-termination-failure | This rule creates OpsItems when the termination of an EC2 auto scaling instance failed. |

| Rule name                                | Description  |
|--|--|
| SSMOpsItems-EBS-snapshot-copy-failed     | This rule creates OpsItems when the system failed to copy an Amazon Elastic Block Store (Amazon EBS) snapshot.   |
| SSMOpsItems-EBS-snapshot-creation-failed | This rule creates OpsItems when the system failed to create an Amazon EBS snapshot.  |
| SSMOpsItems-EBS-volume-performance-issue | This rule corresponds to an AWS Health tracking rule. The rule creates OpsItems whenever there is a performance issue with an Amazon EBS volume (health event = <code>AWS_EBS_DEGRADED_EBS_VOLUME_PERFORMANCE</code> ).  |
| SSMOpsItems-EC2-issue                    | This rule corresponds to an AWS Health tracking rule for unexpected events that affect AWS services or resources. The rule creates OpsItems when, for example, a service sends communications about operational issues that are causing service degradation or to raise awareness about localized resource-level issues. For example, this rule creates an OpsItem for the following event: <code>AWS_EC2_OPERATIONAL_ISSUE</code> . |
| SSMOpsItems-EC2-scheduled-change         | This rule corresponds to an AWS Health tracking rule. AWS can schedule events for your instances, such as rebooting, stopping, or starting instances. The rule creates OpsItems for EC2 scheduled events. For more information about scheduled events, see <a href="#">Scheduled events for your instances</a> in the <i>Amazon EC2 User Guide</i> .   |

| Rule name   | Description  |
|---|--|
| SSMOpsItems-RDS-issue                               | <p>This rule corresponds to an AWS Health tracking rule for unexpected events that affect AWS services or resources. The rule creates OpsItems when, for example, a service sends communications about operational issues that are causing service degradation or to raise awareness about localized resource-level issues. For example, this rule creates an OpsItem for the following events: <code>AWS_RDS_MYSQL_DATA_BASE_CRASHING_REPEATEDLY</code> , <code>AWS_RDS_EXPORT_TASK_FAILED</code> , and <code>AWS_RDS_CONNECTIVITY_ISSUE</code> .</p>   |
| SSMOpsItems-RDS-scheduled-change                    | <p>This rule corresponds to an AWS Health tracking rule. The rule creates OpsItems for Amazon RDS scheduled events. Scheduled events provide information about upcoming changes to your Amazon RDS resources. Some events might recommend that you take action to avoid service disruptions. Other events occur automatically without any action on your part. Your resource might be temporarily unavailable during the scheduled change activity. For example, this rule creates an OpsItem for the following events: <code>AWS_RDS_SYSTEM_UPGRADE_SCHEDULED</code> and <code>AWS_RDS_MAINTENANCE_SCHEDULED</code> . For more information about scheduled events, see <a href="#">Event type categories</a> in the <i>AWS Health User Guide</i>.</p> |
| SSMOpsItems-SSM-maintenance-window-execution-failed | <p>This rule creates OpsItems when the processing of the Systems Manager maintenance window failed.</p>  |

| Rule name   | Description   |
|---|---|
| SSMOpsItems-SSM-maintenance-window-execution-timedout | This rule creates OpsItems when the launch of the Systems Manager maintenance window timed out. |

Use the following procedure to set up OpsCenter.

### To set up OpsCenter

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **OpsCenter**.
3. On the OpsCenter home page, choose **Get started**.
4. On the OpsCenter setup page, choose **Enable this option to have Explorer configure AWS Config and Amazon CloudWatch events to automatically create OpsItems based on commonly-used rules and events**. If you don't choose this option, OpsCenter remains disabled.

#### Note

Amazon EventBridge (formerly Amazon CloudWatch Events) provides all functionality of CloudWatch Events and some new features, such as custom event buses, third-party event sources and schema registry.

5. Choose **Enable OpsCenter**.

After you enable OpsCenter, you can do the following from **Settings**:

- Create CloudWatch alarms using the **Open CloudWatch console** button. For more information, see [Configure CloudWatch alarms to create OpsItems](#).
- Enable operational insights. For more information, see [Analyzing operational insights to reduce OpsItems](#).
- Enable AWS Security Hub findings alarms. For more information, see [Understanding OpsCenter integration with AWS Security Hub](#).

## Contents

- [\(Optional\) Setting up OpsCenter to centrally manage OpsItems across accounts](#)
- [\(Optional\) Set up Amazon SNS to receive notifications about OpsItems](#)

### (Optional) Setting up OpsCenter to centrally manage OpsItems across accounts

You can use Systems Manager OpsCenter to centrally manage OpsItems across multiple AWS accounts in a selected AWS Region. This feature is available after you set up your organization in AWS Organizations. AWS Organizations is an account management service that enables you to consolidate multiple AWS accounts into an organization that you create and centrally manage. AWS Organizations includes account management and consolidated billing capabilities that enable you to better meet the budgetary, security, and compliance needs of your business. For more information, see [What is AWS Organizations?](#) in the *AWS Organizations User Guide*

Users who belong to the AWS Organizations management account can set up a delegated administrator account for Systems Manager. In the context of OpsCenter, delegated administrators can create, edit, and view OpsItems in member accounts. The delegated administrator can also use Systems Manager Automation runbooks to bulk resolve OpsItems or remediate issues with AWS resources that are generating OpsItems.

#### Note

You can assign only one account as the delegated administrator for Systems Manager. For more information, see [Creating an AWS Organizations delegated administrator for Systems Manager](#).

Systems Manager offers the following methods for setting up OpsCenter to centrally manage OpsItems across multiple AWS accounts.

- **Quick Setup:** Quick Setup, a capability of Systems Manager, simplifies set up and configuration tasks for Systems Manager capabilities. For more information, see [AWS Systems Manager Quick Setup](#).

Quick Setup for OpsCenter helps you complete the following tasks for managing OpsItems across accounts:

- Registering an account as the delegated administrator (if the delegated administrator hasn't already been designated)

- Creating required AWS Identity and Access Management (IAM) policies and roles
- Specifying an AWS Organizations organization or organizational units (OUs) where a delegated administrator can manage OpsItems across accounts

For more information, see [\(Optional\) Configure OpsCenter to manage OpsItems across accounts by using Quick Setup](#).

**Note**

Quick Setup isn't available in all AWS Regions where Systems Manager is currently available. If Quick Setup isn't available in a Region where you want to use it to configure OpsCenter to centrally manage OpsItems across multiple accounts, then you must use the manual method. To view a list of AWS Regions where Quick Setup is available, see [Availability of Quick Setup in AWS Regions](#).

- **Manual set up:** If Quick Setup isn't available in the Region where you want to configure OpsCenter to centrally manage OpsItems across accounts, then you can use the manual procedure to do so. For more information, see [\(Optional\) Manually set up OpsCenter to centrally manage OpsItems across accounts](#).

### **(Optional) Configure OpsCenter to manage OpsItems across accounts by using Quick Setup**

Quick Setup, a capability of AWS Systems Manager, simplifies set up and configuration tasks for Systems Manager capabilities. Quick Setup for OpsCenter helps you complete the following tasks for managing OpsItems across accounts:

- Specifying the delegated administrator account
- Creating required AWS Identity and Access Management (IAM) policies and roles
- Specifying an AWS Organizations organization, or a subset of member accounts, where a delegated administrator can manage OpsItems across accounts

When you configure OpsCenter to manage OpsItems across accounts by using Quick Setup, Quick Setup creates the following resources in the specified accounts. These resources give the specified accounts permission to work with OpsItems and use Automation runbooks to fix issues with AWS resources generating OpsItems.

| Resources   | Accounts  |
|---|---|
| <p>AWSServiceRoleForAmazonSSM_AccountDiscovery AWS Identity and Access Management (IAM) service-linked role</p> <p>For more information about this role, see <a href="#">Using roles to collect AWS account information for OpsCenter and Explorer</a>.</p> | <p>AWS Organizations management account and delegated administrator account</p> |
| <p>OpsItem-CrossAccountManagementRole IAM role</p> <p>AWS-SystemsManager-AutomationAdministrationRole IAM role</p>  | <p>Delegated administrator account</p>  |
| <p>OpsItem-CrossAccountExecutionRole IAM role</p> <p>AWS-SystemsManager-AutomationExecutionRole IAM role</p> <p>AWS::SSM::ResourcePolicy Systems Manager resource policy for the default OpsItem group (OpsItemGroup )</p>                                  | <p>All AWS Organizations member accounts</p>                                    |

### Note

If you previously configured OpsCenter to manage OpsItems across accounts using the [manual method](#), you must delete the AWS CloudFormation stacks or stack sets created during Steps 4 and 5 of that process. If those resources exist in your account when you complete the following procedure, Quick Setup fails to configure cross-account OpsItem management properly.

## To configure OpsCenter to manage OpsItems across accounts by using Quick Setup

1. Sign in to the AWS Management Console using the AWS Organizations management account.

2. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
3. In the navigation pane, choose **Quick Setup**.
4. Choose the **Library** tab.
5. Scroll to the bottom and locate the **OpsCenter** configuration tile. Choose **Create**.
6. On the Quick Setup OpsCenter page, in the **Delegated administrator** section, enter an account ID. If you are unable to edit this field, then a delegated administrator account has already been specified for Systems Manager.
7. In the **Targets** section, choose an option. If you choose **Custom**, then select the organizational units (OU) where you want to manage OpsItems across accounts.
8. Choose **Create**.

Quick Setup creates the OpsCenter configuration and deploys the required AWS resources to the designated OUs.

#### **Note**

If you don't want to manage OpsItems across multiple accounts, you can delete the configuration from Quick Setup. When you delete the configuration, Quick Setup deletes the following IAM policies and roles created when the configuration was originally deployed:

- OpsItem-CrossAccountManagementRole from the delegated administrator account
- OpsItem-CrossAccountExecutionRole and SSM::ResourcePolicy from all Organizations member accounts

Quick Setup removes the configuration from all organizational units and AWS Regions where the configuration was originally deployed.

## Troubleshooting issues with a Quick Setup configuration for OpsCenter

This section includes information to help you troubleshoot issues when configuring cross-account OpsItem management using Quick Setup.

### Topics

- [Deployment to these StackSets failed: delegatedAdmin](#)
- [Quick Setup configuration status shows Failed](#)

## Deployment to these StackSets failed: delegatedAdmin

When creating an OpsCenter configuration, Quick Setup deploys two AWS CloudFormation stack sets in the Organizations management account. The stack sets use the following prefix: `AWS-QuickSetup-SSMOpsCenter`. If Quick Setup displays the following error: `Deployment to these StackSets failed: delegatedAdmin` use the following procedure to fix this issue.

### To troubleshoot a StackSets failed:delegatedAdmin error

1. If you received the `Deployment to these StackSets failed: delegatedAdmin` error in a red banner in the Quick Setup console, sign in to the delegated administrator account and the AWS Region designated as the Quick Setup home Region.
2. Open the AWS CloudFormation console at <https://console.aws.amazon.com/cloudformation>.
3. Choose the stack created by your Quick Setup configuration. The stack name includes the following: **AWS-QuickSetup-SSMOpsCenter**.

#### Note

Sometimes CloudFormation deletes failed stack deployments. If the stack isn't available in the **Stacks** table, choose **Deleted** from the filter list.

4. View the **Status** and **Status reason**. For more information about stack statuses, see [Stack status codes](#) in the *AWS CloudFormation User Guide*.
5. To understand the exact step that failed, view the **Events** tab and review each event's **Status**. For more information, see [Troubleshooting](#) in the *AWS CloudFormation User Guide*.

#### Note

If you are unable to resolve the deployment failure using the CloudFormation troubleshooting steps, delete the configuration and try again.

## Quick Setup configuration status shows Failed

If the **Configuration details** table on the **Configuration details** page shows a configuration status of Failed, sign in to the AWS account and Region where it failed.

### To troubleshoot a Quick Setup failure to create an OpsCenter configuration

1. Sign in to the AWS account and the AWS Region where the failure occurred.
2. Open the AWS CloudFormation console at <https://console.aws.amazon.com/cloudformation>.
3. Choose the stack created by your Quick Setup configuration. The stack name includes the following: **AWS-QuickSetup-SSMOpsCenter**.

#### Note

Sometimes CloudFormation deletes failed stack deployments. If the stack isn't available in the **Stacks** table, choose **Deleted** from the filter list.

4. View the **Status** and **Status reason**. For more information about stack statuses, see [Stack status codes](#) in the *AWS CloudFormation User Guide*.
5. To understand the exact step that failed, view the **Events** tab and review each event's **Status**. For more information, see [Troubleshooting](#) in the *AWS CloudFormation User Guide*.

### Member account configuration shows ResourcePolicyLimitExceededException

If a stack status shows `ResourcePolicyLimitExceededException`, the account has previously onboarded to OpsCenter cross-account management by using the [manual method](#). To resolve this issue, you must delete the AWS CloudFormation stacks or stack sets created during Steps 4 and 5 of the manual onboarding process. For more information, see [Delete a stack set](#) and [Deleting a stack on the AWS CloudFormation console](#) in the *AWS CloudFormation User Guide*.

### (Optional) Manually set up OpsCenter to centrally manage OpsItems across accounts

This section describes how to manually configure OpsCenter for cross-account OpsItem management. While this process is still supported, it has been replaced by a newer process that uses Systems Manager Quick Setup. For more information, see [\(Optional\) Configure OpsCenter to manage OpsItems across accounts by using Quick Setup](#).

You can set up a central account to create manual OpsItems for member accounts, and manage and remediate those OpsItems. The central account can be the AWS Organizations management

account, or both the AWS Organizations management account and Systems Manager delegated administrator account. We recommend that you use the Systems Manager delegated administrator account as a central account. You can only use this feature after you configure AWS Organizations.

With AWS Organizations, you can consolidate multiple AWS accounts into an organization that you create and manage centrally. The central account user can create OpsItems for all selected member accounts simultaneously, and manage those OpsItems.

Use the process in this section to enable the Systems Manager service principal in Organizations and configure AWS Identity and Access Management (IAM) permissions for working with OpsItems across accounts.

## Topics

- [Before you begin](#)
- [Step 1: Creating a resource data sync](#)
- [Step 2: Enabling the Systems Manager service principal in AWS Organizations](#)
- [Step 3: Creating the AWSServiceRoleForAmazonSSM\\_AccountDiscovery service-linked role](#)
- [Step 4: Configuring permissions to work with OpsItems across accounts](#)
- [Step 5: Configuring permissions to work with related resources across accounts](#)

### Note

Only OpsItems of type `/aws/issue` are supported when working in OpsCenter across accounts.

## Before you begin

Before you set up OpsCenter to work with OpsItems across accounts, ensure that you have set up the following:

- A Systems Manager delegated administrator account. For more information, see [Configuring a delegated administrator for Explorer](#).
- One organization set up and configured in Organizations. For more information, see [Creating and managing an organization](#) in the *AWS Organizations User Guide*.

- You configured Systems Manager Automation to run automation runbooks across multiple AWS Regions and AWS accounts. For more information, see [Running automations in multiple AWS Regions and accounts](#).

## Step 1: Creating a resource data sync

After you set up and configure AWS Organizations, you can aggregate OpsItems in OpsCenter for an entire organization by creating a resource data sync. For more information, see [Creating a resource data sync](#). When you create the sync, in the **Add accounts** section, be sure to choose the **Include all accounts from my AWS Organizations configuration** option.

## Step 2: Enabling the Systems Manager service principal in AWS Organizations

To enable a user to work with OpsItems across accounts, the Systems Manager service principal must be enabled in AWS Organizations. If you previously configured Systems Manager for multi-account scenarios using other capabilities, the Systems Manager service principal might already be configured in Organizations. Run the following commands from the AWS Command Line Interface (AWS CLI) to verify. If you *haven't* configured Systems Manager for other multi-account scenarios, skip to the next procedure, *To enable the Systems Manager service principal in AWS Organizations*.

### To verify the Systems Manager service principal is enabled in AWS Organizations

1. [Download](#) the latest version of the AWS CLI to your local machine.
2. Open the AWS CLI, and run the following command to specify your credentials and an AWS Region.

```
aws configure
```

The system prompts you to specify the following. In the following example, replace each *user input placeholder* with your own information.

```
AWS Access Key ID [None]: key_name
AWS Secret Access Key [None]: key_name
Default region name [None]: region
Default output format [None]: ENTER
```

3. Run the following command to verify that the Systems Manager service principal is enabled for AWS Organizations.

```
aws organizations list-aws-service-access-for-organization
```

The command returns information similar to that shown in the following example.

```
{
  "EnabledServicePrincipals": [
    {
      "ServicePrincipal":
"member.org.stacksets.cloudformation.amazonaws.com",
      "DateEnabled": "2020-12-11T16:32:27.732000-08:00"
    },
    {
      "ServicePrincipal": "opsdatasync.ssm.amazonaws.com",
      "DateEnabled": "2022-01-19T12:30:48.352000-08:00"
    },
    {
      "ServicePrincipal": "ssm.amazonaws.com",
      "DateEnabled": "2020-12-11T16:32:26.599000-08:00"
    }
  ]
}
```

## To enable the Systems Manager service principal in AWS Organizations

If you haven't previously configured the Systems Manager service principal for Organizations, use the following procedure to do so. For more information about this command, see [enable-aws-service-access](#) in the *AWS CLI Command Reference*.

1. Install and configure the AWS Command Line Interface (AWS CLI), if you haven't already. For information, see [Installing CLI](#) and [Configuring CLI](#).
2. [Download](#) the latest version of the AWS CLI to your local machine.
3. Open the AWS CLI, and run the following command to specify your credentials and an AWS Region.

```
aws configure
```

The system prompts you to specify the following. In the following example, replace each *user input placeholder* with your own information.

```
AWS Access Key ID [None]: key_name
AWS Secret Access Key [None]: key_name
Default region name [None]: region
Default output format [None]: ENTER
```

4. Run the following command to enable the Systems Manager service principal for AWS Organizations.

```
aws organizations enable-aws-service-access --service-principal "ssm.amazonaws.com"
```

### Step 3: Creating the `AWSServiceRoleForAmazonSSM_AccountDiscovery` service-linked role

A service-linked role such as the `AWSServiceRoleForAmazonSSM_AccountDiscovery` role is a unique type of IAM role that is linked directly to an AWS service, such as Systems Manager. Service-linked roles are predefined by the service and include all the permissions that the service requires to call other AWS services on your behalf. For more information about the `AWSServiceRoleForAmazonSSM_AccountDiscovery` service-linked role, see [Service-linked role permissions for Systems Manager account discovery](#).

Use the following procedure to create the `AWSServiceRoleForAmazonSSM_AccountDiscovery` service-linked role by using the AWS CLI. For more information about the command used in this procedure, see [create-service-linked-role](#) in the *AWS CLI Command Reference*.

#### To create the `AWSServiceRoleForAmazonSSM_AccountDiscovery` service-linked role

1. Sign in to the AWS Organizations management account.
2. While signed in to the Organizations management account, run the following command.

```
aws iam create-service-linked-role \
  --aws-service-name accountdiscovery.ssm.amazonaws.com \
  --description "Systems Manager account discovery for AWS Organizations service-
  linked role"
```

### Step 4: Configuring permissions to work with OpsItems across accounts

Use AWS CloudFormation stacksets to create an `OpsItemGroup` resource policy and an IAM execution role that give users permission to work with OpsItems across accounts.

To get started, download and unzip the [OpsCenterCrossAccountMembers.zip](#) file. This file contains the `OpsCenterCrossAccountMembers.yaml` AWS CloudFormation template file. When you create a stack set by using this template, CloudFormation automatically creates the `OpsItemCrossAccountResourcePolicy` resource policy and the `OpsItemCrossAccountExecutionRole` execution role in the account. For more information about creating a stack set, see [Create a stack set](#) in the *AWS CloudFormation User Guide*.

### Important

Note the following important information about this task:

- You must deploy the stackset while signed in to the AWS Organizations management account.
- You must repeat this procedure while signed in to *every* account that you want to *target* for working with OpsItems across accounts, including the delegated administrator account.
- If you want to enable cross-account OpsItems administration in different AWS Regions, choose **Add all regions** in the **Specify regions** section of the template. Cross-account OpsItem administration isn't supported for opt-in Regions.

## Step 5: Configuring permissions to work with related resources across accounts

An OpsItem can include detailed information about impacted resources such as Amazon Elastic Compute Cloud (Amazon EC2) instances or Amazon Simple Storage Service (Amazon S3) buckets. The `OpsItemCrossAccountExecutionRole` execution role, which you created in the previous Step 4, provides OpsCenter with read-only permissions for member accounts to view related resources. You must also create an IAM role to provide management accounts with permission to view and interact with related resources, which you will complete in this task.

To get started, download and unzip the [OpsCenterCrossAccountManagementRole.zip](#) file. This file contains the `OpsCenterCrossAccountManagementRole.yaml` AWS CloudFormation template file. When you create a stack by using this template, CloudFormation automatically creates the `OpsCenterCrossAccountManagementRole` IAM role in the account. For more information about creating a stack, see [Creating a stack on the AWS CloudFormation console](#) in the *AWS CloudFormation User Guide*.

**⚠ Important**

Note the following important information about this task:

- If you plan to specify an account as a delegated administrator for OpsCenter, be sure to specify that AWS account when you create the stack.
- You must perform this procedure while signed in to the AWS Organizations management account and again while signed in to the delegated administrator account.

**(Optional) Set up Amazon SNS to receive notifications about OpsItems**

You can configure OpsCenter to send notifications to an Amazon Simple Notification Service (Amazon SNS) topic when the system creates an OpsItem or updates an existing OpsItem.

Complete the following steps to receive notifications for OpsItems.

- [Step 1: Creating and subscribing to an Amazon SNS topic](#)
- [Step 2: Updating the Amazon SNS access policy](#)
- [Step 3: Updating the AWS KMS access policy](#)

**ℹ Note**

If you turn on AWS Key Management Service (AWS KMS) server-side encryption in Step 2, then you must complete Step 3. Otherwise, you can skip Step 3.

- [Step 4: Turning on default OpsItems rules to send notifications for new OpsItems](#)

**Step 1: Creating and subscribing to an Amazon SNS topic**

To receive notifications, you must create and subscribe to an Amazon SNS topic. For more information, see [Creating an Amazon SNS topic](#) and [Subscribing to an Amazon SNS topic](#) in the *Amazon Simple Notification Service Developer Guide*.

**Note**

If you're using OpsCenter in multiple AWS Regions or accounts, you must create and subscribe to an Amazon SNS topic in *each* Region or account where you want to receive OpsItem notifications.

**Step 2: Updating the Amazon SNS access policy**

You have to associate an Amazon SNS topic with OpsItems. Use the following procedure to set up an Amazon SNS access policy so that Systems Manager can publish OpsItems notifications to the Amazon SNS topic that you created in Step 1.

1. Sign in to the AWS Management Console and open the Amazon SNS console at <https://console.aws.amazon.com/sns/v3/home>.
2. In the navigation pane, choose **Topics**.
3. Choose the topic that you created in Step 1, and then choose **Edit**.
4. Expand **Access policy**.
5. Add the following Sid block to the existing policy. Replace each *example resource placeholder* with your own information.

```
{
  "Sid": "Allow OpsCenter to publish to this topic",
  "Effect": "Allow",
  "Principal": {
    "Service": "ssm.amazonaws.com"
  },
  "Action": "SNS:Publish",
  "Resource": "arn:aws:sns:region:account ID:topic name", // Account ID of the
  SNS topic owner
  "Condition": {
    "StringEquals": {
      "AWS:SourceAccount": "account ID" // Account ID of the OpsItem owner
    }
  }
}
```

**Note**

The `aws:SourceAccount` global condition key protects against the confused deputy scenario. To use this condition key, set the value to the account ID of the OpsItem owner. For more information, see [Confused Deputy](#) in the *IAM User Guide*.

**6. Choose `Save changes`.**

The system now sends notifications to the Amazon SNS topic when OpsItems are created or updated.

**⚠ Important**

If you configure the Amazon SNS topic with an AWS Key Management Service (AWS KMS) server-side encryption key in the Step 2, then complete Step 3. Otherwise, you can skip Step 3.

**Step 3: Updating the AWS KMS access policy**

If you turned on AWS KMS server-side encryption for your Amazon SNS topic, you must also update the access policy of the AWS KMS key that you chose when you configured the topic. Use the following procedure to update the access policy so that Systems Manager can publish OpsItem notifications to the Amazon SNS topic you created in Step 1.

**Note**

OpsCenter doesn't support publishing OpsItems to an Amazon SNS topic that is configured with an AWS managed key.

1. Open the AWS KMS console at <https://console.aws.amazon.com/kms>.
2. To change the AWS Region, use the Region selector in the upper-right corner of the page.
3. In the navigation pane, choose **Customer managed keys**.
4. Choose the ID of the KMS key that you chose when you created the topic.
5. In the **Key policy** section, choose **Switch to policy view**.

6. Choose **Edit**.
7. Add the following Sid block to the existing policy. Replace each *example resource placeholder* with your own information.

```
{
  "Sid": "Allow OpsItems to decrypt the key",
  "Effect": "Allow",
  "Principal": {
    "Service": "ssm.amazonaws.com"
  },
  "Action": ["kms:Decrypt", "kms:GenerateDataKey*"],
  "Resource": "arn:aws:kms:region:account ID:key/key ID"
}
```

In the following example, the new block is entered at line 14.

8. Choose **Save changes**.

#### Step 4: Turning on default OpsItems rules to send notifications for new OpsItems

Default OpsItems rules in Amazon EventBridge aren't configured with an Amazon Resource Name (ARN) for Amazon SNS notifications. Use the following procedure to edit a rule in EventBridge and enter a notifications block.

## To add a notifications block to a default OpsItem rule

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **OpsCenter**.
3. Choose the **OpsItems** tab, and then choose **Configure sources**.
4. Choose the name of the source rule that you want to configure with a notifications block, as shown in the following example.

| Rule   | Category     | Severity | State   |
|--|--------------|----------|---------|
| <a href="#">SSMOpsItems-Autoscaling-instance-launch-failure</a>      | Availability | 2-High   | enabled |
| <a href="#">SSMOpsItems-Autoscaling-instance-termination-failure</a> | Availability | 2-High   | enabled |
| <a href="#">SSMOpsItems-EBS-snapshot-copy-failed</a>                 | Availability | 2-High   | enabled |
| <a href="#">SSMOpsItems-EBS-snapshot-creation-failed</a>             | Availability | 2-High   | enabled |
| <a href="#">SSMOpsItems-EBS-volume-performance-issue</a>             | Performance  | 3-Medium | enabled |
| <a href="#">SSMOpsItems-EC2-issue</a>                                | Availability | 2-High   | enabled |

The rule opens in Amazon EventBridge.

5. On the rule details page, on the **Targets** tab, choose **Edit**.
6. In the **Additional settings** section, choose **Configure input transformer**.
7. In the **Template** box, add a notifications block in the following format.

```
"notifications": [{"arn": "arn:aws:sns:region:account ID:topic name"}],
```

Here's an example.

```
"notifications": [{"arn": "arn:aws:sns:us-west-2:1234567890:MySNSTopic"}],
```

Enter the notifications block before the resources block, as shown in the following example for the US West (Oregon) (us-west-2) Region.

```
{
  "title": "EBS snapshot copy failed",
  "description": "CloudWatch Event Rule SSMOpsItems-EBS-snapshot-copy-failed was triggered. Your EBS snapshot copy has failed. See below for more details.",
```

```

"category": "Availability",
"severity": "2",
"source": "EC2",
"notifications": [{
  "arn": "arn:aws:sns:us-west-2:1234567890:MySNSTopic"
}],
"resources": <resources>,
"operationalData": {
  "/aws/dedup": {
    "type": "SearchableString",
    "value": "{\"dedupString\": \"SSM0psItems-EBS-snapshot-copy-failed\"}"
  },
  "/aws/automations": {
    "value": "[ { \"automationType\": \"AWS:SSM:Automation\",
\"automationId\": \"AWS-CopySnapshot\" } ]"
  },
  "failure-cause": {
    "value": <failure - cause>
  },
  "source": {
    "value": <source>
  },
  "start-time": {
    "value": <start - time>
  },
  "end-time": {
    "value": <end - time>
  }
}
}

```

8. Choose **Confirm**.
9. Choose **Next**.
10. Choose **Next**.
11. Choose **Update rule**.

The next time that the system creates an OpsItem for the default rule, it publishes a notification to the Amazon SNS topic.

## Integrate OpsCenter with other AWS services

OpsCenter, a capability of AWS Systems Manager, integrates with multiple AWS services to diagnose and remediate issues with AWS resources. You must set up the AWS service before you integrate it with OpsCenter.

By default, the following AWS services are integrated with OpsCenter and can create OpsItems automatically:

- [Amazon CloudWatch](#)
- [Amazon CloudWatch Application Insights](#)
- [Amazon EventBridge](#)
- [AWS Config](#)
- [AWS Systems Manager Incident Manager](#)

You have to integrate the following services with OpsCenter to create OpsItems automatically:

- [Amazon DevOps Guru](#)
- [AWS Security Hub](#)

When any of these services create an OpsItem, you can manage and remediate the OpsItem from OpsCenter. For more information, see [Manage OpsItems](#) and [Remediate OpsItem issues](#).

For more information about each AWS service and how it integrates with OpsCenter, see the following topics.

### Topics

- [Understanding OpsCenter integration with Amazon CloudWatch](#)
- [Understanding OpsCenter integration with Amazon CloudWatch Application Insights](#)
- [Understanding OpsCenter integration with Amazon DevOps Guru](#)
- [Understanding OpsCenter integration with Amazon EventBridge](#)
- [Understanding OpsCenter integration with AWS Config](#)
- [Understanding OpsCenter integration with AWS Security Hub](#)
- [Understanding OpsCenter integration with Incident Manager](#)

## Understanding OpsCenter integration with Amazon CloudWatch

Amazon CloudWatch monitors your AWS resources and services, and displays metrics on every AWS service that you use. CloudWatch creates an OpsItem when an alarm enters the alarm state. For example, you can configure an alarm to automatically create an OpsItem if there is a spike in HTTP errors generated by your Application Load Balancer.

Some alarms that you can configure in CloudWatch to create OpsItems are shown in the following list:

- Amazon DynamoDB: database read and write actions reach a threshold
- Amazon EC2: CPU utilization reaches a threshold
- AWS billing: estimated charges reach a threshold
- Amazon EC2: an instance fails a status check
- Amazon Elastic Block Store (EBS): disk space utilization reaches a threshold

You can either create an alarm or edit an existing alarm to create an OpsItem. For more information, see [Configure CloudWatch alarms to create OpsItems](#).

When you enable OpsCenter using Integrated Setup, it integrates CloudWatch with OpsCenter.

## Understanding OpsCenter integration with Amazon CloudWatch Application Insights

Using Amazon CloudWatch Application Insights, you can set up the most appropriate monitors for your application resources to continuously analyze data for signs of problems with your applications. When you configure application resources in CloudWatch Application Insights, you can choose to have the system create OpsItems in OpsCenter. An OpsItem is created on the OpsCenter console for every problem detected with the application. For information, see [Set up, configure, and manage your application for monitoring](#) in the *Amazon CloudWatch User Guide*.

### Note

Starting October 16, 2023, the title and description for OpsItems created by CloudWatch Application Insights now use the following improved format:

```
OpsItem title: [<APPLICATION NAME>: <RESOURCE ID>] <PROBLEM SUMMARY>
```

**OpsItem description:**

CloudWatch Application Insights has detected a problem in application <APPLICATION NAME>.

Problem summary: <PROBLEM SUMMARY>

Problem ID: <PROBLEM ID> (hyperlinks to the Application Insights problem summary page)

Problem Status: <PROBLEM STATUS>

Insight: <INSIGHT>

Here is an example:

AWS Systems Manager &gt; OpsCenter &gt; [exampleApplication: exampleCluster] ECS: Network received bytes

## Understanding OpsCenter integration with Amazon DevOps Guru

Amazon DevOps Guru applies machine learning to analyze your operational data, application metrics, and application events to identify behaviors that deviate from normal operating patterns.

If you enable DevOps Guru to generate an OpsItem in OpsCenter, each insight generates a new OpsItem. You can use OpsCenter to manage your OpsItems.

DevOps Guru automatically creates OpsItems. You can enable Amazon DevOps Guru to create OpsItems by using Quick Setup, which is a capability of Systems Manager. The system creates OpsItems by using the [AWSServiceRoleForDevOpsGuru](#) AWS Identity and Access Management (IAM) service-linked role.

### To integrate OpsCenter with DevOps Guru

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Quick Setup**.
3. On the **Customize DevOps Guru configuration options** page, choose the **Library** tab.
4. In the **DevOps Guru** pane, choose **Create**.
5. For **Configuration options**, select **Enable AWS Systems Manager OpsItems**.
6. Select **Create** after you complete the setup.

### Understanding OpsCenter integration with Amazon EventBridge

Amazon EventBridge delivers a stream of events that describe changes in AWS resources. When you enable OpsCenter using Integrated Setup, it integrates EventBridge with OpsCenter, and enables default EventBridge rules. Based on these rules, EventBridge creates OpsItems. Using rules, you can filter and route events to OpsCenter for investigation and remediation.

#### Note

Amazon EventBridge (formerly Amazon CloudWatch Events) provides all functionality of CloudWatch Events and some new features, such as custom event buses, third-party event sources and schema registry.

Following are some rules that you can configure in EventBridge to create an OpsItem:

- Security Hub: security alert issued
- Amazon DynamoDB a throttling event
- Amazon Elastic Compute Cloud Auto Scaling: failure to launch an instance

- Systems Manager: failure to run an automation
- AWS Health: an alert for scheduled maintenance
- Amazon EC2: instance state changed from running to stop

Based on your requirements, you can either create a rule or edit an existing rule to create an OpsItems. For instructions on how to edit a rule to create an OpsItem, see [Configure EventBridge rules to create OpsItems](#).

## Understanding OpsCenter integration with AWS Config

AWS Config provides a detailed view of the configuration of AWS resources in your AWS account.

AWS Config does not integrate *directly* with OpsCenter. Instead, you create an AWS Config rule that sends an event to Amazon EventBridge, such as when AWS Config detects a noncompliant instance. Then EventBridge evaluates that event against an EventBridge rule you've created. If the rule matches, EventBridge transforms the event to an OpsItem and transmits it to OpsCenter as the destination target.

Using this OpsItem, you can track details of the noncompliant resource, record investigative actions, and provide access to consistent remediation actions.

### Related info

[Configure EventBridge rules to create OpsItems](#)

[Using AWS Systems Manager OpsCenter and AWS Config for compliance monitoring](#)

## Understanding OpsCenter integration with AWS Security Hub

AWS Security Hub collects security data, called *findings*, from across AWS accounts and services. Using a set of rules to detect and generate findings, Security Hub helps you identify, prioritize, and remediate security issues for the resources you manage. After you configure integration, as described in this topic, Systems Manager creates OpsItems for Security Hub findings in OpsCenter.

### Note

OpsCenter has bidirectional integration with Security Hub. This means that if you update the **Status** or **Severity** field for an OpsItem related to a security finding, the system synchronizes the changes with Security Hub. Likewise, any changes to a finding are automatically updated in the corresponding OpsItems in OpsCenter.

When an OpsItem is created from a Security Hub finding, Security Hub metadata is automatically added to the operational data field of the OpsItem. If this metadata is deleted, the bidirectional updates no longer function.

By default, Systems Manager creates OpsItems for critical and high severity findings. You can manually configure OpsCenter to create OpsItems for medium and low severity findings. OpsCenter doesn't create OpsItems for informational findings as they don't require remediation. For more information about Security Hub severity levels, see [Severity](#) in the *AWS Security Hub API Reference*.

### Before you begin

Before you configure OpsCenter to create OpsItems based on Security Hub findings, verify that you completed the Security Hub set up tasks. For more information, see [Setting up Security Hub](#) in the *AWS Security Hub User Guide*.

When you integrate Security Hub with OpsCenter, the system creates OpsItems by using the `AWSServiceRoleForSystemsManagerOpsDataSync` IAM service-linked role. For more information about this role, see [Using roles to create OpsData and OpsItems for Explorer](#).

#### Warning

Note the following important information about pricing for OpsCenter integration with Security Hub:

- If you are logged into the Security Hub administrator account when you configure OpsCenter and Security Hub integration, the system creates OpsItems for findings in the administrator *and* all member accounts. The OpsItems are all created *in the administrator account*. Depending on a variety of factors, this can lead to an unexpectedly large bill from AWS.

If you are logged into a member account when you configure integration, the system only creates OpsItems for findings in that individual account. For more information about the Security Hub administrator account, member accounts, and their relation to the EventBridge event feed for findings, see [Types of Security Hub integration with EventBridge](#) in the *AWS Security Hub User Guide*.

- For each finding that creates an OpsItem, you are charged the regular price for creating the OpsItem. You are also charged if you edit the OpsItem or if the corresponding finding is updated in Security Hub (which triggers an OpsItem update).

### To configure OpsCenter to create OpsItems for Security Hub findings

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **OpsCenter**.
3. Choose **Settings**.
4. In the **Security Hub findings** section, choose **Edit**.
5. Choose the slider to change **Disabled** to **Enabled**.
6. If you want the system to create OpsItems for medium or low severity findings, toggle these options.
7. Choose **Save** to save your configuration.

Use the following procedure if you no longer want the system to create OpsItems for Security Hub findings.

### To stop receiving OpsItems for Security Hub findings

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **OpsCenter**.
3. Choose **Settings**.
4. In the **Security Hub findings** section, choose **Edit**.
5. Choose the slider to change **Enabled** to **Disabled**. If you aren't able to toggle the slider, Security Hub hasn't been enabled for your AWS account.
6. Choose **Save** to save your configuration. OpsCenter no longer creates OpsItems based on Security Hub findings.

### Important

A Systems Manager delegated administrator or the AWS Organizations management account can enable Security Hub findings in OpsCenter for multiple accounts and AWS Regions by creating a resource data sync in Explorer. If the **Security Hub** source is enabled in Explorer and a resource data sync exists that targets the member account where you disabled Security Hub integration, then the settings selected by your administrator take precedence. OpsCenter continues to create OpsItems for Security Hub findings. To stop creating OpsItems for Security Hub findings in a member account targeted by a resource data sync, contact your administrator and ask them to remove your account from the resource data sync or turn off the **Security Hub** source in Explorer. For information about changing settings in Explorer, see [Editing Systems Manager Explorer data sources](#).

## Understanding OpsCenter integration with Incident Manager

Incident Manager, a capability of AWS Systems Manager, provides an incident management console that helps you mitigate and recover from incidents affecting your AWS hosted applications. An *incident* is any unplanned interruption or reduction in quality of services. After you set up and configure [Incident Manager](#), the system automatically creates OpsItems in OpsCenter.

When the system creates an incident in Incident Manager, it also creates an OpsItem in OpsCenter, and displays the incident as a related item. If the OpsItem already exists, Incident Manager doesn't create an OpsItem. The first OpsItem is known as the parent OpsItem. If an incident grows in scale and scope, you can add incidents to an existing OpsItem. If required, you can manually create an incident for an OpsItem. After an incident is closed, you can create an analysis in Incident Manager to review and improve the remediation process for similar issues.

By default, OpsCenter integrates with Incident Manager. If Incident Manager is not set up, the OpsCenter page displays a message to set up Incident Manager. When Incident Manager creates an OpsItem, you can manage and remediate the OpsItem from OpsCenter. For instructions on creating an incident for an OpsItem, see [Creating an incident for an OpsItem](#).

## Create OpsItems

After you set up OpsCenter, a capability of AWS Systems Manager, and integrate it with your AWS services, your AWS services automatically create OpsItems based on default rules, events, or alarms.

You can view the statuses and severity levels of default Amazon EventBridge rules. If required, you can create or edit these rules from Amazon EventBridge. You can also view alarms from Amazon CloudWatch, and create or edit alarms. Using rules and alarms, you can configure events for which you want to generate OpsItems automatically.

When the system creates an OpsItem, it's in the **Open** status. You can change the status to **In progress** when you start investigation of the OpsItem and to **Resolved** after you remediate the OpsItem. For more information about how to configure alarms and rules in AWS services to create OpsItems and how to create OpsItems manually, see the following topics.

## Topics

- [Configure EventBridge rules to create OpsItems](#)
- [Configure CloudWatch alarms to create OpsItems](#)
- [Create OpsItems manually](#)

## Configure EventBridge rules to create OpsItems

When Amazon EventBridge receives an event, it creates a new OpsItem based on default rules. You can create a rule or edit an existing rule to set OpsCenter as the target of an EventBridge event. For information about how to create an event rule, see [Creating a rule for an AWS service](#) in the *Amazon EventBridge User Guide*.

### To configure an EventBridge rule to create OpsItems in OpsCenter

1. Open the Amazon EventBridge console at <https://console.aws.amazon.com/events/>.
2. In the navigation pane, choose **Rules**.
3. On the **Rules** page, for **Event bus**, choose **default**.
4. For **Rules**, choose a rule by selecting the check box next to its name.
5. Select the name of the rule to open its details page. In **Rule details**, verify that **Status** is set to **Enabled**.

#### Note

If required, you can update the status using **Edit** in the upper-right corner of the page.

6. Choose the **Targets** tab.
7. On the **Targets** tab, choose **Edit**.

8. For **Target types**, select **AWS service**.
9. For **Select a target**, choose **Systems Manager OpsItem**.
10. For many target types, EventBridge needs permission to send events to the target. In these cases, EventBridge can create the AWS Identity and Access Management (IAM) role needed for your rule to run:
  - To create an IAM role automatically, choose **Create a new role for this specific resource**.
  - To use an IAM role that you created to give EventBridge permission to create OpsItems in OpsCenter, choose **Use existing role**.
11. In **Additional settings**, for **Configure target input**, choose **Input Transformer**.

You can use the **Input transformer** option to specify a deduplication string and other important information for OpsItems, such as title and severity.

12. Choose **Configure input transformer**.
13. In **Target input transformer**, for **Input path**, specify the values to parse from the triggering event. For example, to parse the start time, end time, and other details from the event that triggers the rule, use the following JSON.

```
{
  "end-time": "$.detail.EndTime",
  "failure-cause": "$.detail.cause",
  "resources": "$.resources",
  "source": "$.detail.source",
  "start-time": "$.detail.StartTime"
}
```

14. For **Template**, specify the information to send to the target. For example, use the following JSON to pass information to OpsCenter. The information is used to create an OpsItem.

 **Note**

If the input template is in the JSON format, then the object value in the template can't include quotes. For example, the values for resources, failure-cause, source, start time, and end time can't be in quotes.

```
{
  "title": "EBS snapshot copy failed",
```

```

    "description": "CloudWatch Event Rule SSM0psItems-EBS-snapshot-copy-failed was
triggered. Your EBS snapshot copy has failed. See below for more details.",
    "category": "Availability",
    "severity": "2",
    "source": "EC2",
    "resources": <resources>,
    "operationalData": {
      "/aws/dedup": {
        "type": "SearchableString",
        "value": "{\"dedupString\": \"SSM0psItems-EBS-snapshot-copy-failed\"}"
      },
      "/aws/automations": {
        "value": "[ { \"automationType\": \"AWS:SSM:Automation\",
\"automationId\": \"AWS-CopySnapshot\" } ]"
      },
      "failure-cause": {
        "value": <failure-cause>
      },
      "source": {
        "value": <source>
      },
      "start-time": {
        "value": <start-time>
      },
      "end-time": {
        "value": <end-time>
      }
    }
  }
}

```

For more information about these fields, see [Transforming target input](#) in the *Amazon EventBridge User Guide*.

15. Choose **Confirm**.
16. Choose **Next**.
17. Choose **Next**.
18. Choose **Update rule**.

After an OpsItem is created from an event, you can view the event details by opening the OpsItem and scrolling down to the **Private operational data** section. For information about how to configure the options in an OpsItem, see [Manage OpsItems](#).

## Configure CloudWatch alarms to create OpsItems

During the integrated setup of OpsCenter, a capability of AWS Systems Manager, you enable Amazon CloudWatch to automatically create OpsItems based on common alarms. You can create an alarm or edit an existing alarm to create OpsItems in OpsCenter.

CloudWatch creates a new service-linked role in AWS Identity and Access Management (IAM) when you configure an alarm to create OpsItems. The new role is named `AWSServiceRoleForCloudWatchAlarms_ActionSSM`. For more information about CloudWatch service-linked roles, see [Using service-linked roles for CloudWatch](#) in the *Amazon CloudWatch User Guide*.

When a CloudWatch alarm generates an OpsItem, the OpsItem displays **CloudWatch alarm - '*alarm\_name*' is in ALARM state**.

To view details about a specific OpsItem, choose the OpsItem and then choose the **Related resource details** tab. You can manually edit OpsItems to change details, such as the severity or category. However, when you edit the severity or the category of an alarm, Systems Manager can't update the severity or category of OpsItems that are already created from the alarm. If an alarm created an OpsItem and if you specified a deduplication string, the alarm won't create additional OpsItems even if you edit the alarm in CloudWatch. If the OpsItem is resolved in OpsCenter, CloudWatch will create a new OpsItem.

For more information about configuring CloudWatch alarms, see the following topics.

### Topics

- [Configuring a CloudWatch alarm to create OpsItems \(console\)](#)
- [Configuring an existing CloudWatch alarm to create OpsItems \(programmatically\)](#)

### Configuring a CloudWatch alarm to create OpsItems (console)

You can manually create an alarm or update an existing alarm to create OpsItems from Amazon CloudWatch.

### To create a CloudWatch alarm and configure Systems Manager as a target of that alarm

1. Complete steps 1–9 as specified in [Create a CloudWatch alarm based on a static threshold](#) in the *Amazon CloudWatch User Guide*.
2. In the **Systems Manager action** section, choose **Add Systems Manager OpsCenter action**.

3. Choose **OpsItems**.
4. For **Severity**, choose from 1 to 4.
5. (Optional) For **Category**, choose a category for the OpsItem.
6. Complete steps 11–13 as specified in [Create a CloudWatch alarm based on a static threshold](#) in the *Amazon CloudWatch User Guide*.
7. Choose **Next** and complete the wizard.

### To edit an existing alarm and configure Systems Manager as a target of that alarm

1. Open the CloudWatch console at <https://console.aws.amazon.com/cloudwatch/>.
2. In the navigation pane, choose **Alarms**.
3. Select the alarm, and then choose **Actions, Edit**.
4. (Optional) Change settings in the **Metrics** and **Conditions** sections, and then choose **Next**.
5. In the **Systems Manager** section, choose **Add Systems Manager OpsCenter action**.
6. For **Severity**, choose a number.

#### Note

Severity is a user-defined value. You or your organization determine what each severity value means and any service-level agreement associated with each severity.

7. (Optional) For **Category**, choose an option.
8. Choose **Next** and complete the wizard.

### Configuring an existing CloudWatch alarm to create OpsItems (programmatically)

You can configure Amazon CloudWatch alarms to create OpsItems programmatically by using the AWS Command Line Interface (AWS CLI), AWS CloudFormation templates, or Java code snippets.

#### Topics

- [Before you begin](#)
- [Configuring CloudWatch alarms to create OpsItems \(AWS CLI\)](#)
- [Configuring CloudWatch alarms to create or update OpsItems \(CloudFormation\)](#)
- [Configuring CloudWatch alarms to create or update OpsItems \(Java\)](#)

## Before you begin

If you edit an existing alarm programmatically or create an alarm that creates OpsItems, you must specify an Amazon Resource Name (ARN). This ARN identifies Systems Manager OpsCenter as the target for OpsItems created from the alarm. You can customize the ARN so that OpsItems created from the alarm include specific information such as severity or category. Each ARN includes the information described in the following table.

| Parameter             | Details  |
|-----------------------|--|
| Region (required)     | The AWS Region where the alarm exists. For example: <code>us-west-2</code> . For information about AWS Regions where you can use OpsCenter , see <a href="#">AWS Systems Manager endpoints and quotas</a> .          |
| account_ID (required) | The same AWS account ID used to create the alarm. For example: <code>123456789012</code> . The account ID must be followed by a colon (:) and the parameter <code>opsitem</code> as shown in the following examples. |
| severity (required)   | A user-defined severity level for OpsItems created from the alarm. Valid values: 1, 2, 3, 4  |
| Category(optional)    | A category for OpsItems created from the alarm. Valid values: Availability , Cost, Performance , Recovery, and Security.   |

Create the ARN by using the following syntax. This ARN doesn't include the optional Category parameter.

```
arn:aws:ssm:Region:account_ID:opsitem:severity
```

Following is an example.

```
arn:aws:ssm:us-west-2:123456789012:opsitem:3
```

To create an ARN that uses the optional Category parameter, use the following syntax.

```
arn:aws:ssm:Region:account_ID:opsitem:severity#CATEGORY=category_name
```

Following is an example.

```
arn:aws:ssm:us-west-2:123456789012:opsitem:3#CATEGORY=Security
```

## Configuring CloudWatch alarms to create OpsItems (AWS CLI)

This command requires that you specify an ARN for the alarm-actions parameter. For information about how to create the ARN, see [Before you begin](#).

### To configure a CloudWatch alarm to create OpsItems (AWS CLI)

1. Install and configure the AWS Command Line Interface (AWS CLI), if you haven't already.

For information, see [Installing or updating the latest version of the AWS CLI](#).

2. Run the following command to collect information about the alarm that you want to configure.

```
aws cloudwatch describe-alarms --alarm-names "alarm name"
```

3. Run the following command to update an alarm. Replace each *example resource placeholder* with your own information.

```
aws cloudwatch put-metric-alarm --alarm-name name \  
--alarm-description "description" \  
--metric-name name --namespace namespace \  
--statistic statistic --period value --threshold value \  
--comparison-operator value \  
--dimensions "dimensions" --evaluation-periods value \  
--alarm-actions  
arn:aws:ssm:Region:account_ID:opsitem:severity#CATEGORY=category_name \  
--unit unit
```

Here's an example.

## Linux & macOS

```
aws cloudwatch put-metric-alarm --alarm-name cpu-mon \
--alarm-description "Alarm when CPU exceeds 70 percent" \
--metric-name CPUUtilization --namespace AWS/EC2 \
--statistic Average --period 300 --threshold 70 \
--comparison-operator GreaterThanThreshold \
--dimensions "Name=InstanceId,Value=i-12345678" --evaluation-periods 2 \
--alarm-actions arn:aws:ssm:us-east-1:123456789012:opsitem:3#CATEGORY=Security \
--unit Percent
```

## Windows

```
aws cloudwatch put-metric-alarm --alarm-name cpu-mon ^
--alarm-description "Alarm when CPU exceeds 70 percent" ^
--metric-name CPUUtilization --namespace AWS/EC2 ^
--statistic Average --period 300 --threshold 70 ^
--comparison-operator GreaterThanThreshold ^
--dimensions "Name=InstanceId,Value=i-12345678" --evaluation-periods 2 ^
--alarm-actions arn:aws:ssm:us-east-1:123456789012:opsitem:3#CATEGORY=Security ^
--unit Percent
```

## Configuring CloudWatch alarms to create or update OpsItems (CloudFormation)

This section includes AWS CloudFormation templates that you can use to configure CloudWatch alarms to automatically create or update OpsItems. Each template requires that you specify an ARN for the AlarmActions parameter. For information about how to create the ARN, see [Before you begin](#).

**Metric alarm** – Use the following CloudFormation template to create or update a CloudWatch metric alarm. The alarm specified in this template monitors Amazon Elastic Compute Cloud (Amazon EC2) instance status checks. If the alarm enters the ALARM state, it creates an OpsItem in OpsCenter.

```
{
  "AWSTemplateFormatVersion": "2010-09-09",
  "Parameters" : {
    "RecoveryInstance" : {
```

```

        "Description" : "The EC2 instance ID to associate this alarm with.",
        "Type" : "AWS::EC2::Instance::Id"
    }
},
"Resources": {
    "RecoveryTestAlarm": {
        "Type": "AWS::CloudWatch::Alarm",
        "Properties": {
            "AlarmDescription": "Run a recovery action when instance status check fails
for 15 consecutive minutes.",
            "Namespace": "AWS/EC2" ,
            "MetricName": "StatusCheckFailed_System",
            "Statistic": "Minimum",
            "Period": "60",
            "EvaluationPeriods": "15",
            "ComparisonOperator": "GreaterThanThreshold",
            "Threshold": "0",
            "AlarmActions": [ {"Fn::Join" : [""],
["arn:arn:aws:ssm:Region:account_ID:opsitem:severity#CATEGORY=category_name",
{ "Ref" : "AWS::Partition" }, ":ssm:", { "Ref" : "AWS::Region" }, { "Ref" : "AWS::
AccountId" }, ":opsitem:3" ]]} ],
            "Dimensions": [{"Name": "InstanceId","Value": {"Ref": "RecoveryInstance"}}]
        }
    }
}
}
}

```

**Composite alarm** – Use the following CloudFormation template to create or update a composite alarm. A composite alarm consists of multiple metric alarms. If the alarm enters the ALARM state, it creates an OpsItem in OpsCenter.

```

"Resources":{
    "HighResourceUsage":{
        "Type":"AWS::CloudWatch::CompositeAlarm",
        "Properties":{
            "AlarmName":"HighResourceUsage",
            "AlarmRule":"(ALARM(HighCPUUsage) OR ALARM(HighMemoryUsage)) AND NOT
ALARM(DeploymentInProgress)",
            "AlarmActions":"arn:aws:ssm:Region:account_ID:opsitem:severity#CATEGORY=category_name",
            "AlarmDescription":"Indicates that the system resource usage is high while
no known deployment is in progress"
        },
    },
}

```

```

    "DependsOn":[
      "DeploymentInProgress",
      "HighCPUUsage",
      "HighMemoryUsage"
    ]
  },
  "DeploymentInProgress":{
    "Type":"AWS::CloudWatch::CompositeAlarm",
    "Properties":{
      "AlarmName":"DeploymentInProgress",
      "AlarmRule":"FALSE",
      "AlarmDescription":"Manually updated to TRUE/FALSE to disable other
alarms"
    }
  },
  "HighCPUUsage":{
    "Type":"AWS::CloudWatch::Alarm",
    "Properties":{
      "AlarmDescription":"CPUusageishigh",
      "AlarmName":"HighCPUUsage",
      "ComparisonOperator":"GreaterThanThreshold",
      "EvaluationPeriods":1,
      "MetricName":"CPUUsage",
      "Namespace":"CustomNamespace",
      "Period":60,
      "Statistic":"Average",
      "Threshold":70,
      "TreatMissingData":"notBreaching"
    }
  },
  "HighMemoryUsage":{
    "Type":"AWS::CloudWatch::Alarm",
    "Properties":{
      "AlarmDescription":"Memoryusageishigh",
      "AlarmName":"HighMemoryUsage",
      "ComparisonOperator":"GreaterThanThreshold",
      "EvaluationPeriods":1,
      "MetricName":"MemoryUsage",
      "Namespace":"CustomNamespace",
      "Period":60,
      "Statistic":"Average",
      "Threshold":65,
      "TreatMissingData":"breaching"
    }
  }
}

```

```
}  
}
```

## Configuring CloudWatch alarms to create or update OpsItems (Java)

This section includes Java code snippets that you can use to configure CloudWatch alarms to automatically create or update OpsItems. Each snippet requires that you specify an ARN for the `validSsmActionStr` parameter. For information about how to create the ARN, see [Before you begin](#).

**A specific alarm** – Use the following Java code snippet to create or update a CloudWatch alarm. The alarm specified in this template monitors Amazon EC2 instance status checks. If the alarm enters the ALARM state, it creates an OpsItem in OpsCenter.

```
import com.amazonaws.services.cloudwatch.AmazonCloudWatch;  
import com.amazonaws.services.cloudwatch.AmazonCloudWatchClientBuilder;  
import com.amazonaws.services.cloudwatch.model.ComparisonOperator;  
import com.amazonaws.services.cloudwatch.model.Dimension;  
import com.amazonaws.services.cloudwatch.model.PutMetricAlarmRequest;  
import com.amazonaws.services.cloudwatch.model.PutMetricAlarmResult;  
import com.amazonaws.services.cloudwatch.model.StandardUnit;  
import com.amazonaws.services.cloudwatch.model.Statistic;  
  
private void putMetricAlarmWithSsmAction() {  
    final AmazonCloudWatch cw =  
        AmazonCloudWatchClientBuilder.defaultClient();  
  
    Dimension dimension = new Dimension()  
        .withName("InstanceId")  
        .withValue(instanceId);  
  
    String validSsmActionStr =  
        "arn:aws:ssm:Region:account_ID:opsitem:severity#CATEGORY=category_name";  
  
    PutMetricAlarmRequest request = new PutMetricAlarmRequest()  
        .withAlarmName(alarmName)  
        .withComparisonOperator(  
            ComparisonOperator.GreaterThanThreshold)  
        .withEvaluationPeriods(1)  
        .withMetricName("CPUUtilization")  
        .withNamespace("AWS/EC2")  
        .withPeriod(60)  
        .withStatistic(Statistic.Average)
```

```

        .withThreshold(70.0)
        .withActionsEnabled(false)
        .withAlarmDescription(
            "Alarm when server CPU utilization exceeds 70%")
        .withUnit(StandardUnit.Seconds)
        .withDimensions(dimension)
        .withAlarmActions(validSsmActionStr);

    PutMetricAlarmResult response = cw.putMetricAlarm(request);
}

```

**Update all alarms** – Use the following Java code snippet to update all CloudWatch alarms in your AWS account to create OpsItems when an alarm enters the ALARM state.

```

import com.amazonaws.services.cloudwatch.AmazonCloudWatch;
import com.amazonaws.services.cloudwatch.AmazonCloudWatchClientBuilder;
import com.amazonaws.services.cloudwatch.model.DescribeAlarmsRequest;
import com.amazonaws.services.cloudwatch.model.DescribeAlarmsResult;
import com.amazonaws.services.cloudwatch.model.MetricAlarm;

private void listMetricAlarmsAndAddSsmAction() {
    final AmazonCloudWatch cw = AmazonCloudWatchClientBuilder.defaultClient();

    boolean done = false;
    DescribeAlarmsRequest request = new DescribeAlarmsRequest();

    String validSsmActionStr =
        "arn:aws:ssm:Region:account_ID:opsitem:severity#CATEGORY=category_name";

    while(!done) {

        DescribeAlarmsResult response = cw.describeAlarms(request);

        for(MetricAlarm alarm : response.getMetricAlarms()) {
            // assuming there are no alarm actions added for the metric alarm
            alarm.setAlarmActions(ImmutableList.of(validSsmActionStr));
        }

        request.setNextToken(response.getNextToken());

        if(response.getNextToken() == null) {
            done = true;
        }
    }
}

```

```
}  
}
```

## Create OpsItems manually

When you find an operational issue, you can manually create an OpsItem from OpsCenter, a capability of AWS Systems Manager, to manage and resolve the issue.

If you set up OpsCenter for cross-account administration, a Systems Manager delegated administrator or AWS Organizations management account can create OpsItems for member accounts. For more information, see [\(Optional\) Manually set up OpsCenter to centrally manage OpsItems across accounts](#).

You can create OpsItems by using the AWS Systems Manager console, the AWS Command Line Interface (AWS CLI), or AWS Tools for Windows PowerShell.

### Topics

- [Creating OpsItems manually \(console\)](#)
- [Creating OpsItems manually \(AWS CLI\)](#)
- [Creating OpsItems manually \(PowerShell\)](#)

### Creating OpsItems manually (console)

You can manually create OpsItems using the AWS Systems Manager console. When you create an OpsItem, it's displayed in your OpsCenter account. If you set up OpsCenter for cross-account administration, OpsCenter provides the delegated administrator or management account with the option to create OpsItems for selected member accounts. For more information, see [\(Optional\) Manually set up OpsCenter to centrally manage OpsItems across accounts](#).

### To create an OpsItem using the AWS Systems Manager console

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **OpsCenter**.
3. Choose **Create OpsItem**. If you don't see this button, choose the **OpsItems** tab, and then choose **Create OpsItem**.

4. (Optional) Choose **Other account**, and then choose the account where you want to create the OpsItem.

 **Note**

This step is required if you're creating OpsItems for a member account.

5. For **Title**, enter a descriptive name to help you understand the purpose of the OpsItem.
6. For **Source**, enter the type of impacted AWS resource or other source information to help users understand the origin of the OpsItem.

 **Note**

You can't edit the **Source** field after you create the OpsItem.

7. (Optional) For **Priority**, choose the priority level.
8. (Optional) For **Severity**, choose the severity level.
9. (Optional) For **Category**, choose a category.
10. For **Description**, enter information about this OpsItem including (if applicable) steps for reproducing the issue.

 **Note**

The console supports most markdown formatting in the OpsItem description field. For more information, see [Using Markdown in the Console](#) in the *Getting Started with the AWS Management Console Getting Started Guide*.

11. For **Deduplication string**, enter words that the system can use to check for duplicate OpsItems. For more information about deduplication strings, see [Managing duplicate OpsItems](#).
12. (Optional) For **Notifications**, specify the Amazon Resource Name (ARN) of the Amazon SNS topic where you want notifications sent when this OpsItem is updated. You must specify an Amazon SNS ARN that is in the same AWS Region as the OpsItem.
13. (Optional) For **Related resources**, choose **Add** to specify the ID or ARN of the impacted resource and any related resources.
14. Choose **Create OpsItem**.

If successful, the page displays the OpsItem. When a delegated administrator or management account creates an OpsItem for selected member accounts, the new OpsItems are displayed in the OpsCenter of the administrator and members accounts. For information about how to configure the options in an OpsItem, see [Manage OpsItems](#).

## Creating OpsItems manually (AWS CLI)

The following procedure describes how to create an OpsItem by using the AWS Command Line Interface (AWS CLI).

### To create an OpsItem using the AWS CLI

1. Install and configure the AWS Command Line Interface (AWS CLI), if you haven't already.

For information, see [Installing or updating the latest version of the AWS CLI](#).

2. Open the AWS CLI and run the following command to create an OpsItem. Replace each *example resource placeholder* with your own information.

```
aws ssm create-ops-item \
  --title "Descriptive_title" \
  --description "Information_about_the_issue" \
  --priority Number_between_1_and_5 \
  --source Source_of_the_issue \
  --operational-data Up_to_20_KB_of_data_or_path_to_JSON_file \
  --notifications Arn="SNS_ARN_in_same_Region" \
  --tags "Key=key_name,Value=a_value"
```

### Specify operational data from a file

When you create an OpsItem, you can specify operational data from a file. The file must be a JSON file, and the contents of the file must use the following format.

```
{
  "key_name": {
    "Type": "SearchableString",
    "Value": "Up to 20 KB of data"
  }
}
```

Here is an example.

```
aws ssm create-ops-item ^
  --title "EC2 instance disk full" ^
  --description "Log clean up may have failed which caused the disk to be full" ^
  --priority 2 ^
  --source ec2 ^
  --operational-data file:///Users/TestUser1/Desktop/OpsItems/opsData.json ^
  --notifications Arn="arn:aws:sns:us-west-1:12345678:TestUser1" ^
  --tags "Key=EC2,Value=Production"
```

**Note**

For information about how to enter JSON-formatted parameters on the command line on different local operating systems, see [Using quotation marks with strings in the AWS CLI](#) in the *AWS Command Line Interface User Guide*.

The system returns information like the following.

```
{
  "OpsItemId": "oi-1a2b3c4d5e6f"
}
```

3. Run the following command to view details about the OpsItem that you created.

```
aws ssm get-ops-item --ops-item-id ID
```

The system returns information like the following.

```
{
  "OpsItem": {
    "CreatedBy": "arn:aws:iam::12345678:user/TestUser",
    "CreatedTime": 1558386334.995,
    "Description": "Log clean up may have failed which caused the disk to be
full",
    "LastModifiedBy": "arn:aws:iam::12345678:user/TestUser",
    "LastModifiedTime": 1558386334.995,
    "Notifications": [
      {
        "Arn": "arn:aws:sns:us-west-1:12345678:TestUser"
      }
    ]
  }
}
```

```
    ],
    "Priority": 2,
    "RelatedOpsItems": [],
    "Status": "Open",
    "OpsItemId": "oi-1a2b3c4d5e6f",
    "Title": "EC2 instance disk full",
    "Source": "ec2",
    "OperationalData": {
      "EC2": {
        "Value": "12345",
        "Type": "SearchableString"
      }
    }
  }
}
```

4. Run the following command to update the OpsItem. This command changes the status from Open (the default) to InProgress.

```
aws ssm update-ops-item --ops-item-id ID --status InProgress
```

The command has no output.

5. Run the following command again to verify that the status changed to InProgress.

```
aws ssm get-ops-item --ops-item-id ID
```

## Examples of creating an OpsItem

The following code examples show you how to create an OpsItem by using the Linux management portal, macOS, or Windows.

### Linux management portal or macOS

The following command creates an OpsItem when an Amazon Elastic Compute Cloud (Amazon EC2) instance disk is full.

```
aws ssm create-ops-item \  
  --title "EC2 instance disk full" \  
  --description "Log clean up may have failed which caused the disk to be full" \  
  --priority 2 \  
  --source ec2
```

```
--source ec2 \
--operational-data '{"EC2":{"Value":"12345","Type":"SearchableString"}}' \
--notifications Arn="arn:aws:sns:us-west-1:12345678:TestUser1" \
--tags "Key=EC2,Value=ProductionServers"
```

The following command uses the `/aws/resources` key in `OperationalData` to create an OpsItem with an Amazon DynamoDB related resource.

```
aws ssm create-ops-item \
--title "EC2 instance disk full" \
--description "Log clean up may have failed which caused the disk to be full" \
--priority 2 \
--source ec2 \
--operational-data '{"/aws/resources":{"Value":["arn:aws:dynamodb:us-west-2:12345678:table/OpsItems"],"Type":"SearchableString"}}' \
--notifications Arn="arn:aws:sns:us-west-2:12345678:TestUser"
```

The following command uses the `/aws/automations` key in `OperationalData` to create an OpsItem that specifies the `AWS-ASGEnterStandby` document as an associated Automation runbook.

```
aws ssm create-ops-item \
--title "EC2 instance disk full" \
--description "Log clean up may have failed which caused the disk to be full" \
--priority 2 \
--source ec2 \
--operational-data '{"/aws/automations":{"Value":["automationId\n": "AWS-ASGEnterStandby\n", "automationType\n": "AWS::SSM::Automation\n"]},"Type":"SearchableString"}}' \
--notifications Arn="arn:aws:sns:us-west-2:12345678:TestUser"
```

## Windows

The following command creates an OpsItem when an Amazon Relational Database Service (Amazon RDS) instance is not responding.

```
aws ssm create-ops-item ^
--title "RDS instance not responding" ^
--description "RDS instance not responding to ping" ^
--priority 1 ^
--source RDS ^
```

```
--operational-data={"RDS":{"Value":"abcd"},"Type":"SearchableString"}} ^
--notifications Arn="arn:aws:sns:us-west-1:12345678:TestUser1" ^
--tags "Key=RDS,Value=ProductionServers"
```

The following command uses the `/aws/resources` key in `OperationalData` to create an OpsItem with an Amazon EC2 instance related resource.

```
aws ssm create-ops-item ^
  --title "EC2 instance disk full" ^
  --description "Log clean up may have failed which caused the disk to be full" ^
  --priority 2 ^
  --source ec2 ^
  --operational-data={"/aws/resources":{"Value":{"arn":"arn:aws:ec2:us-east-1:123456789012:instance/i-1234567890abcdef0"},"Type":"SearchableString"}}
```

The following command uses the `/aws/automations` key in `OperationalData` to create an OpsItem that specifies the `AWS-RestartEC2Instance` runbook as an associated Automation runbook.

```
aws ssm create-ops-item ^
  --title "EC2 instance disk full" ^
  --description "Log clean up may have failed which caused the disk to be full" ^
  --priority 2 ^
  --source ec2 ^
  --operational-data={"/aws/automations":{"Value":{"automationId":"AWS-RestartEC2Instance","automationType":"AWS::SSM::Automation"},"Type":"SearchableString"}}
```

## Creating OpsItems manually (PowerShell)

The following procedure describes how to create an OpsItem by using AWS Tools for Windows PowerShell.

### To create an OpsItem using AWS Tools for Windows PowerShell

1. Open AWS Tools for Windows PowerShell and run the following command to specify your credentials.

```
Set-AWSCredentials -AccessKey key-name -SecretKey key-name
```

2. Run the following command to set the AWS Region for your PowerShell session.

```
Set-DefaultAWSRegion -Region Region
```

3. Run the following command to create a new OpsItem. Replace each *example resource placeholder* with your own information. This command specifies a Systems Manager Automation runbook for remediating this OpsItem.

```
$opsItem = New-Object Amazon.SimpleSystemsManagement.Model.OpsItemDataValue
$opsItem.Type = [Amazon.SimpleSystemsManagement.OpsItemDataType]::SearchableString
$opsItem.Value = '[{"automationId\":"runbook_name","\automatationType\":"
\AWS::SSM::Automation\"}]'
$newHash = @{" /aws/
automations"=[Amazon.SimpleSystemsManagement.Model.OpsItemDataValue]$opsItem}

New-SSMOpsItem `
  -Title "title" `
  -Description "description" `
  -Priority priority_number `
  -Source AWS_service `
  -OperationalData $newHash
```

If successful, the command outputs the ID of the new OpsItem.

The following example specifies the Amazon Resource Name (ARN) of an impaired Amazon Elastic Compute Cloud (Amazon EC2) instance.

```
$opsItem = New-Object Amazon.SimpleSystemsManagement.Model.OpsItemDataValue
$opsItem.Type = [Amazon.SimpleSystemsManagement.OpsItemDataType]::SearchableString
$opsItem.Value = '[{"arn\":"arn:aws:ec2:us-east-1:123456789012:instance/
i-1234567890abcdef0\"}]'
$newHash = @{" /aws/
resources"=[Amazon.SimpleSystemsManagement.Model.OpsItemDataValue]$opsItem}
New-SSMOpsItem -Title "EC2 instance disk full still" -Description "Log clean up may
have failed which caused the disk to be full" -Priority 2 -Source ec2 -OperationalData
$newHash
```

## Manage OpsItems

OpsCenter, a capability of AWS Systems Manager, tracks OpsItems from their creation to resolution. If you set up OpsCenter for cross-account administration, a delegated administrator

or management account can manage OpsItems from their account. For more information, see [\(Optional\) Manually set up OpsCenter to centrally manage OpsItems across accounts](#).

You can view and manage OpsItems by using the following pages in the Systems Manager console:

- **Summary** – Displays a count of open and in-progress OpsItems, count of OpsItems by source and age, and operational insights. You can filter OpsItems by source and OpsItems status.
- **OpsItems** – Displays a list of OpsItems with multiple fields of information, such as title, ID, priority, description, the source of the OpsItem, and the date and time of last update. Using this page, you can manually create OpsItems, configure sources, change the status of an OpsItem, and filter OpsItems by new incidents. You can choose an OpsItem to display its **OpsItems details** page.
- **OpsItem details** – Provides detailed insights and tools that you can use to manage an OpsItem. The OpsItems details page has the following tabs:
  - **Overview** – Displays related resources, runbooks that ran in the last 30 days, and a list of available runbooks that you can run. You can also view similar OpsItems, add operational data, and add related OpsItems.
  - **Related resource details** – Displays information about the resource from several AWS services. Expand the **Resource details** section to view information about this resource as provided by the AWS service that hosts it. You can also toggle through other related resources associated with this OpsItem by using the **Related resources** list.

For more information about how to manage OpsItems, see the following topics.

## Topics

- [Viewing details of an OpsItem](#)
- [Editing an OpsItem](#)
- [Adding related resources to an OpsItem](#)
- [Adding related OpsItems to an OpsItem](#)
- [Adding operational data to an OpsItem](#)
- [Creating an incident for an OpsItem](#)
- [Managing duplicate OpsItems](#)
- [Analyzing operational insights to reduce OpsItems](#)

- [Viewing OpsCenter logs and reports](#)

## Viewing details of an OpsItem

To get a comprehensive view of an OpsItem, use the **OpsItem details** page in the OpsCenter console. The **Overview** page displays the following information:

- **OpsItems details**– Displays general information for the selected OpsItem.
- **Related Resources** – A related resource is the impacted resource or the resource that initiated the event that created the OpsItem.
- **Automation executions in the last 30 days** – A list of runbooks that ran in last 30 days.
- **Runbooks** – You can choose a runbook from a list of available runbooks.
- **Similar OpsItems** – This is a system-generated list of OpsItems that might be related or of interest to you. To generate the list, the system scans the titles and descriptions of all OpsItems and returns OpsItems that use similar words.
- **Operational data** – Operational data is custom data that provides useful reference details about the OpsItem. For example, you can specify log files, error strings, license keys, troubleshooting tips, or other relevant data.
- **Related OpsItems** – You can specify the IDs of OpsItems that are in some way related to the current OpsItem.
- **Related Resource Details** – Displays data providers, including Amazon CloudWatch metrics and alarms, AWS CloudTrail logs, and details from AWS Config.

## To view details of an OpsItem

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **OpsCenter**.
3. Choose an OpsItem to view its details.

## Editing an OpsItem

The **OpsItem details** section includes information about an OpsItem, including the description, title, source, OpsItem ID, and the status.

You can edit a single OpsItem or you can select multiple OpsItems and edit the

following fields: **Status**, **Priority**, **Severity**, **Category**.

When Amazon EventBridge creates an OpsItem, it populates the **Title**, **Source**, and **Description** fields. You can edit the **Title** and **Description** fields, but you can't edit the **Source** field.

 **Note**

The console supports most markdown formatting in the OpsItem description field. For more information, see [Using Markdown in the Console](#) in the *Getting Started with the AWS Management Console Getting Started Guide*.

Generally, you can edit the following configurable data for an OpsItem:

- **Title** – Name of the OpsItem. The source creates the title of the OpsItem.
- **Description** – Information about this OpsItem including (if applicable) steps for reproducing the issue.
- **Status** – Status of an OpsItem. For a list of valid status values, see [OpsItem Status](#) in the *AWS Systems Manager API Reference*.
- **Priority** – Priority of an OpsItem can be between 1 and 5. We recommend that your organization determine what each priority level means and a corresponding service level agreement for each level.
- **Severity** – Severity of an OpsItem can be between 1 to 4, where 1 is critical, 2 is high, 3 is medium, and 4 is low.
- **Category** – Category of an OpsItem can be availability, cost, performance, recovery, or security.
- **Notifications** – When you edit an OpsItem, you can specify the Amazon Resource Name (ARN) of an Amazon Simple Notification Service topic in the **Notifications** field. By specifying an ARN, you ensure that all stakeholders receive a notification when the OpsItem is edited, including a status change. For more information, see the [Amazon Simple Notification Service Developer Guide](#).

 **Important**

The Amazon SNS topic must exist in the same AWS Region as the OpsItem. If the topic and the OpsItem are in different Regions, the system returns an error.

OpsCenter has bidirectional integration with AWS Security Hub. When you update an OpsItem status and severity related to a security finding, those changes are automatically sent to Security Hub to ensure you always see the latest and correct information.

When an OpsItem is created from a Security Hub finding, Security Hub metadata is automatically added to the operational data field of the OpsItem. If this metadata is deleted, the bidirectional updates no longer function.

### To edit OpsItem details

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **OpsCenter**.
3. Choose an OpsItem ID to open the details page or choose multiple OpsItems. If you choose multiple OpsItems, you can only edit the status, priority, severity, or category. If you edit multiple OpsItems, OpsCenter updates and saves your changes as soon as you choose the new status, priority, severity, or category.
4. In the **OpsItem details** section, choose **Edit**.
5. Edit the details of the OpsItem according to the requirements and guidelines specified by your organization.
6. When you're finished, choose **Save**.

### Adding related resources to an OpsItem

Each OpsItem includes a **Related resources** section that lists the Amazon Resource Name (ARN) of the related resource. A *related resource* is the impacted AWS resource that needs to be investigated.

If Amazon EventBridge creates the OpsItem, the system automatically populates the OpsItem with the ARN of the resource. You can manually specify ARNs of related resources. For certain ARN types, OpsCenter automatically creates a deep link that displays details about the resource directly in the OpsCenter console. For example, if you specify the ARN of an Amazon Elastic Compute Cloud (Amazon EC2) instance as a related resource, then OpsCenter pulls in details about that EC2 instance. This allows you to view detailed information about your impacted AWS resources without having to leave OpsCenter.

## To view and add related resources to an OpsItem

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **OpsCenter**.
3. Choose the **OpsItems** tab.
4. Choose an OpsItem ID.

| ID                              | Title                   | Status | Source |
|---------------------------------|-------------------------|--------|--------|
| <a href="#">oi-a80f1dbb4464</a> | EC2 instance stopped    | ⌵ Open | EC2    |
| <a href="#">oi-0cdb512b47ed</a> | EC2 instance terminated | ⌵ Open | EC2    |
| <a href="#">oi-06f350858b55</a> | EC2 instance terminated | ⌵ Open | EC2    |

5. To view information about the impacted resource, choose the **Related resources details** tab.

EC2 instance terminated Open

Overview Related resource details

Related resource:  Previous Next

Expand all Open session Run automation ▼ [View resource in original console](#)

▼ **CloudWatch Metrics**

CPU Utilization (Percent) Network In (Bytes) Network Out (Bytes)

This tab displays information about the resource from several AWS services. Expand the **Resource details** section to view information about this resource as provided by the AWS service that hosts it. You can also toggle through other related resources associated with this OpsItem by using the **Related resources** list.

6. To add additional related resources, choose the **Overview** tab.
7. In the **Related resources** section, choose **Add**.

8. For **Resource type**, choose a resource from the list.
9. For **Resource ID**, enter either the ID or the Amazon Resource Name (ARN). The type of information you choose depends on the resource that you chose in the previous step.

**Note**

You can manually add the ARNs of additional related resources. Each OpsItem can list a maximum of 100 related resource ARNs.

The following table lists the resource types that automatically create deep links to related resources.

### Supported resource types

| Resource name                       | ARN format   |
|-------------------------------------|--|
| AWS Certificate Manager certificate | <code>arn:aws:acm: <i>region</i>:<i>account-id</i> :certificate/ <i>certificate-id</i></code>  |
| Amazon EC2 Auto Scaling group       | <code>arn:aws:autoscaling: <i>region</i>:<i>account-id</i> :autoScalingGroup: <i>groupid</i>:autoScalingGroupName/ <i>groupfriendlyname</i></code> |
| Amazon CloudFront distribution      | <code>arn:aws:cloudfront:: <i>account-id</i> :* </code>  |
| AWS CloudFormation stack            | <code>arn:aws:cloudformation: <i>region</i>:<i>account-id</i> :stack/<i>stackname</i> /<i>additionalidentifier</i></code>                          |
| Amazon CloudWatch alarm             | <code>arn:aws:cloudwatch: <i>region</i>:<i>account-id</i> :alarm:<i>alarm-name</i></code>  |

| Resource name  | ARN format  |
|--|---|
| AWS CloudTrail trail                                       | <code>arn:aws:cloudtrail: <i>region</i>:<i>account-id</i> :trail/<i>trailname</i></code>                                    |
| AWS CodeBuild project                                      | <code>arn:aws:codebuild: <i>region</i>:<i>account-id</i> :<i>resourcetype</i> /<i>resource</i></code>                       |
| AWS CodePipeline   | <code>arn:aws:codepipeline: <i>region</i>:<i>account-id</i> :<i>resource-specifier</i></code>                               |
| Amazon DevOps Guru insight                                 | <code>arn:aws:devops-guru: <i>region</i>:<i>account-id</i> :insight/ <i>proactive or reactive</i>/<i>resource-id</i></code> |
| Amazon DynamoDB table                                      | <code>arn:aws:dynamodb: <i>region</i>:<i>account-id</i> :table/<i>tablename</i></code>                                      |
| Amazon Elastic Compute Cloud (Amazon EC2) customer gateway | <code>arn:aws:ec2: <i>region</i>:<i>account-id</i> :customer-gateway/ <i>cgw-id</i></code>                                  |
| Amazon EC2 elastic IP                                      | <code>arn:aws:ec2: <i>region</i>:<i>account-id</i> :eip/<i>eipalloc-id</i></code>   |
| Amazon EC2 Dedicated Host                                  | <code>arn:aws:ec2: <i>region</i>:<i>account-id</i> :dedicated-host/ <i>host-id</i></code>                                   |
| Amazon EC2 instance  | <code>arn:aws:ec2: <i>region</i>:<i>account-id</i> :instance/ <i>instance-id</i></code>                                     |
| Amazon EC2 internet gateway                                | <code>arn:aws:ec2: <i>region</i>:<i>account-id</i> :internet-gateway/ <i>igw-id</i></code>                                  |

| Resource name  | ARN format  |
|--|---|
| Amazon EC2 network access control list (network ACL) | <code>arn:aws:ec2: <i>region</i>:<i>account-id</i> :network-acl/ <i>nacl-id</i></code>                      |
| Amazon EC2 network interface                         | <code>arn:aws:ec2: <i>region</i>:<i>account-id</i> :network-interface/ <i>eni-id</i></code>                 |
| Amazon EC2 route table                               | <code>arn:aws:ec2: <i>region</i>:<i>account-id</i> :route-table/ <i>route-table-id</i></code>               |
| Amazon EC2 security group                            | <code>arn:aws:ec2: <i>region</i>:<i>account-id</i> :security-group/ <i>security-group-id</i></code>         |
| Amazon EC2 subnet                                    | <code>arn:aws:ec2: <i>region</i>:<i>account-id</i> :subnet/<i>subnet-id</i></code>                          |
| Amazon EC2 volume                                    | <code>arn:aws:ec2: <i>region</i>:<i>account-id</i> :volume/<i>volume-id</i></code>                          |
| Amazon EC2 VPC                                       | <code>arn:aws:ec2: <i>region</i>:<i>account-id</i> :vpc/<i>vpc-id</i></code>                                |
| Amazon EC2 VPN connection                            | <code>arn:aws:ec2: <i>region</i>:<i>account-id</i> :vpn-connection/ <i>vpn-id</i></code>                    |
| Amazon EC2 VPN gateway                               | <code>arn:aws:ec2: <i>region</i>:<i>account-id</i> :vpn-gateway/ <i>vgw-id</i></code>                       |
| AWS Elastic Beanstalk application                    | <code>arn:aws:elasticbeanstalk: <i>region</i>:<i>account-id</i> :application/ <i>applicationname</i></code> |

| Resource name   | ARN format   |
|---|--|
| Elastic Load Balancing (Classic Load Balancer)          | <code>arn:aws:elasticloadbalancing: <i>region</i>:<i>account-id</i> :loadbalancer/ <i>name</i></code>  |
| Elastic Load Balancing (Application Load Balancer)      | <code>arn:aws:elasticloadbalancing: <i>region</i>:<i>account-id</i> :loadbalancer/app/ <i>load-balancer-name</i> /<i>load-balancer-id</i></code> |
| Elastic Load Balancing (Network Load Balancer)          | <code>arn:aws:elasticloadbalancing: <i>region</i>:<i>account-id</i> :loadbalancer/net/ <i>load-balancer-name</i> /<i>load-balancer-id</i></code> |
| AWS Identity and Access Management (IAM) group          | <code>arn:aws:iam:: <i>account-id</i> :group/<i>group-name</i></code>  |
| IAM policy  | <code>arn:aws:iam:: <i>account-id</i> :policy/<i>policy-name</i></code>  |

## Adding related OpsItems to an OpsItem

By using **Related OpsItems** of the **OpsItems Details** page, you can investigate operations issues and provide context for an issue. OpsItems can be related in different ways, including a parent-child relationship between OpsItems, a root cause, or a duplicate. You can associate one OpsItem with another to display it in the **Related OpsItem** section. You can specify a maximum of 10 IDs for other OpsItems that are related to the current OpsItem.

| Related OpsItems (2)     |                                 |        |                         |        |
|--------------------------|---------------------------------|--------|-------------------------|--------|
| <input type="checkbox"/> | ID                              | Status | Title                   | Source |
| <input type="checkbox"/> | <a href="#">oi-0cdb512b47ed</a> | 🔔 Open | EC2 instance terminated | EC2    |
| <input type="checkbox"/> | <a href="#">oi-06f350858b55</a> | 🔔 Open | EC2 instance terminated | EC2    |

## To add a related OpsItem

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.

2. In the navigation pane, choose **OpsCenter**.
3. Choose an OpsItem ID to open the details page.
4. In the **Related OpsItem** section, choose **Add**.
5. For **OpsItem ID**, specify an ID.
6. Choose **Add**.

## Adding operational data to an OpsItem

Operational data is custom data that provides useful reference details about an OpsItem. You can enter multiple key-value pairs of operational data. For example, you can specify log files, error strings, license keys, troubleshooting tips, or other relevant data. The maximum length of the key can be 128 characters, and the maximum size of the value can be 20 KB.

**Operational data**

Enter one or more key names and values. Ops Center supports searching and filtering OpsItems by using key names and values that are marked searchable

| Key            | Value   | Searchable                                  | Remove |
|----------------|---|---|--------|
| event-time     | 2019-06-04T00:33:35Z  | <input type="radio"/> Searchable            | Remove |
| instance-state | stopped   | <input type="radio"/> Searchable            | Remove |
| Log data       | 6093] ata1: PATA max MWDMA2 cmd<br>0x1f0 ct! 0x3f6 bmdma 0xc100 jrq 14<br>[ 1.981012] ata2: PATA max MWDMA2 | <input checked="" type="radio"/> Searchable | Remove |

Add item

You can make the data searchable by other users in the account, or you can restrict search access. Searchable data means that all users with access to the OpsItem **Overview** page (as provided by the [DescribeOpsItems](#) API operation) can view and search on the specified data. Operational data that isn't searchable is only viewable by users who have access to the OpsItem (as provided by the [GetOpsItem](#) API operation).

## To add operational data to an OpsItem

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.

2. In the navigation pane, choose **OpsCenter**.
3. Choose an OpsItem ID to open its details page.
4. Expand **Operational data**.
5. If no operational data exists for the OpsItem, choose **Add**. If operational data already exists for the OpsItem, choose **Manage**.

After you create operational data, you can edit the key and the value, remove the operational data, or add additional key-value pairs by choosing **Manage**.

6. For **Key**, specify a word or words to help users understand the purpose of the data.

#### **Important**

Operational data keys *can't* begin with the following: amazon, aws, amzn, ssm, /amazon, /aws, /amzn, /ssm.

7. For **Value**, specify the data.
8. Choose **Save**.

#### **Note**

You can filter OpsItems by using the **Operational data** operator on the **OpsItems** page. In the **Search** box, choose **Operational data**, and then enter a key-value pair in JSON. You must enter the key-value pair by using the following format: `{"key": "key_name", "value": "a_value"}`

## Creating an incident for an OpsItem

Use the following procedure to manually create an incident for an OpsItem to track and manage it in AWS Systems Manager Incident Manager, which is a capability of AWS Systems Manager. An *incident* is any unplanned interruption or reduction in quality of services. For more information about Incident Manager, see [the section called "Integrate OpsCenter with other AWS services"](#).

### To manually create an incident for an OpsItem

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.

2. In the navigation pane, choose **OpsCenter**.
3. If Incident Manager created an OpsItem for you, choose it and go to step 5. If not, choose **Create OpsItem** and complete the form. If you don't see this button, choose the **OpsItems** tab, and then choose **Create OpsItem**.
4. If you created an OpsItem, open it.
5. Choose **Start Incident**.
6. For **Response plan**, choose the Incident Manager response plan that you want to assign to this incident.
7. (Optional) For **Title**, enter a descriptive name to help other team members understand the nature of the incident. If you don't enter a new title, OpsCenter creates the OpsItem and the corresponding incident in Incident Manager using the title in the response plan.
8. (Optional) For **Incident impact**, choose an impact level for this incident. If you don't choose an impact level, OpsCenter creates the OpsItem and the corresponding incident in Incident Manager using the impact level in the response plan.
9. Choose **Start**.

## Managing duplicate OpsItems

OpsCenter can receive multiple duplicate OpsItems for a single source from multiple AWS services. OpsCenter uses a combination of built-in logic and configurable deduplication strings to avoid creating duplicate OpsItems. AWS Systems Manager applies deduplication built-in logic when the [CreateOpsItem](#) API operation is called.

AWS Systems Manager uses the following deduplication logic:

1. When creating the OpsItem, Systems Manager creates and stores a hash based on the deduplication string and the resource that initiated the OpsItem.
2. When another request is made to create an OpsItem, the system checks the deduplication string of the new request.
3. If a matching hash exists for this deduplication string, Systems Manager checks the status of the existing OpsItem. If the status of an existing OpsItem is open or in progress, the OpsItem is not created. If the existing OpsItem is resolved, Systems Manager creates a new OpsItem.

After you create an OpsItem, you *can't* edit or change the deduplication strings in that OpsItem.

To manage duplicate OpsItems, you can do the following:

- Edit the deduplication string for an Amazon EventBridge rule that targets OpsCenter. For more information, see [Editing a deduplication string in a default EventBridge rule](#).
- Specify a deduplication string when you manually create an OpsItem. For more information, see [Specifying a deduplication string using AWS CLI](#).
- Review and resolve duplicate OpsItems using operational insights. You can use runbooks to resolve duplicate OpsItems.

To help you resolve duplicate OpsItems and reduce the number of OpsItems created by a source, Systems Manager provides automation runbooks. For information, see [Resolving duplicate OpsItems based on insights](#).

## Editing a deduplication string in a default EventBridge rule

Use the following procedure to specify a deduplication string for an EventBridge rule that targets OpsCenter.

### To edit a deduplication string for an EventBridge rule

1. Sign in to the AWS Management Console and open the Amazon EventBridge console at <https://console.aws.amazon.com/events/>.
2. In the navigation pane, choose **Rules**.
3. Choose a rule, and then choose **Edit**.
4. Go to the **Select target(s)** page.
5. In the **Additional settings** section, choose **Configure input transformer**.
6. In the **Template** box, locate the "operationalData": { "/aws/dedup" JSON entry and the deduplication strings that you want to edit.

The deduplication string entry in EventBridge rules uses the following JSON format.

```
"operationalData": { "/aws/dedup": {"type": "SearchableString","value":  
  "{\\"dedupString\\":\\"Words the system should use to check for duplicate  
  OpsItems\\"}"}}
```

Here is an example.

```
"operationalData": { "/aws/dedup": {"type": "SearchableString","value":  
  "{\\"dedupString\\":\\"SSM0psCenter-EBS-volume-performance-issue\\"}"}}
```

7. Edit the deduplication strings, and then choose **Confirm**.
8. Choose **Next**.
9. Choose **Next**.
10. Choose **Update rule**.

## Specifying a deduplication string using AWS CLI

You can specify a deduplication string when you manually create a new OpsItem by using either the AWS Systems Manager console or the AWS CLI. For information about entering deduplication strings when you manually create an OpsItem in the console, see [Create OpsItems manually](#). If you're using the AWS CLI, you can enter the deduplication string for the `OperationalData` parameter. The parameter syntax uses JSON, as shown in the following example.

```
--operational-data '{"/aws/dedup":{"Value":{"\"dedupString\": \"Words the system should use to check for duplicate OpsItems\"},\"Type\":\"SearchableString\"}}'
```

Here is an example command that specifies a deduplication string of `disk full`.

### Linux & macOS

```
aws ssm create-ops-item \
  --title "EC2 instance disk full" \
  --description "Log clean up may have failed which caused the disk to be full" \
  --priority 1 \
  --source ec2 \
  --operational-data '{"/aws/dedup":{"Value":{"\"dedupString\": \"disk full\"},\"Type\":\"SearchableString\"}}' \
  --tags "Key=EC2,Value=ProductionServers" \
  --notifications Arn="arn:aws:sns:us-west-1:12345678:TestUser"
```

### Windows

```
aws ssm create-ops-item ^
  --title "EC2 instance disk full" ^
  --description "Log clean up may have failed which caused the disk to be full" ^
  --priority 1 ^
  --source EC2 ^
  --operational-data="{\"/aws/dedup\":{\"Value\":{\"\"dedupString\": \"disk full\"},\"Type\": \"SearchableString\"}} ^
```

```
--tags "Key=EC2,Value=ProductionServers" --notifications Arn="arn:aws:sns:us-west-1:12345678:TestUser"
```

## Analyzing operational insights to reduce OpsItems

OpsCenter *operational insights* display information about duplicate OpsItems. OpsCenter automatically analyzes OpsItems in your account and generates three types of *insights*. You can view this information in the **Operational insights** section of the OpsCenter **Summary** tab.

- **Duplicate OpsItems** – An insight is generated when eight or more OpsItems have the same title for the same resource.
- **Most common titles** – An insight is generated when more than 50 OpsItems have the same title.
- **Resources generating the most OpsItems** – An insight is generated when an AWS resource has more than 10 open OpsItems. These insights and their corresponding resources are displayed in the **Resources generating the most OpsItems** table on the OpsCenter **Summary** tab. Resources are listed in decreasing order of OpsItem count.

### Note

OpsCenter creates **Resources generating the most OpsItems** insights for the following resource types:

- Amazon Elastic Compute Cloud (Amazon EC2) instances
- Amazon EC2 security groups
- Amazon EC2 Auto Scaling group
- Amazon Relational Database Service (Amazon RDS) database
- Amazon RDS cluster
- AWS Lambda function
- Amazon DynamoDB table
- Elastic Load Balancing load balancer
- Amazon Redshift cluster
- AWS Certificate Manager certificate
- Amazon Elastic Block Store volume

OpsCenter enforces a limit of 15 insights per type. If a type reaches this limit, OpsCenter stops displaying more insights for that type. To view additional insights, you must resolve all OpsItems associated with an OpsInsight of that type. If a pending insight is prevented from being displayed in the console because of the 15-insight limit, that insight becomes visible after another insight is closed.

When you choose an insight, OpsCenter displays information about the affected OpsItems and resources. The following screenshot shows an example with the details of a duplicate OpsItem insight.

## Duplicate OpsItems: 1122334455

### Insight details

|  |   |
|--|---|
| <p>Insight type<br/>Duplicate OpsItems</p> <p>Affected OpsItems<br/>100 <a href="#">↗</a></p> <p>Affected resources<br/><a href="#">i-06bd38270</a></p> <p>Description<br/>Multiple unresolved OpsItems have the same title 'EC2 Instance Launch Unsuccessful' and involve the same resource 'i-06bd38270'</p> | <p>Status<br/>🔽 Open</p> <p>Date created<br/>14 Aug 2020 20:00:00 GMT</p> <p>Last updated<br/>5 Sep 2020 20:00:00 GMT</p> |
|--|---|

### Recommended runbooks (1)

| Document name | Description  | Execution ID | Start time |
|---------------|--|--------------|------------|
|               | Bulk resolve all unresolved OpsItems with the title 'EC2 Instance Launch |              |            |

Operational insights are turned off by default. For more information about working with operational insights, see the following topics.

## Topics

- [Enabling operational insights](#)
- [Resolving duplicate OpsItems based on insights](#)

- [Disabling operational insights](#)

## Enabling operational insights

You can enable operational insights on the **OpsCenter** page in the Systems Manager console. When you enable operational insights, Systems Manager creates an AWS Identity and Access Management (IAM) service-linked role called `AWSServiceRoleForAmazonSSM_OpsInsights`. A service-linked role is a unique type of IAM role that is linked directly to Systems Manager. Service-linked roles are predefined and include all the permissions that the service requires to call other AWS services on your behalf. For more information about the `AWSServiceRoleForAmazonSSM_OpsInsights` service-linked role, see [Using roles to create operational insight OpsItems in Systems Manager OpsCenter](#).

### Note

Note the following important information:

- Your AWS account is charged for operational insights. For more information, see [AWS Systems Manager Pricing](#).
- OpsCenter periodically refreshes insights using a batch process. This means the list of insights displayed in OpsCenter might be out of sync.

Use the following procedure to enable and view operational insights in OpsCenter.

### To enable and view operational insights

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **OpsCenter**.
3. In the **Operational insight is available** message box, choose **Enable**. If you don't see this message, scroll down to the **Operational insights** section and choose **Enable**.
4. After you enable this feature, on the **Summary** tab, scroll down to the **Operational insights** section.
5. To view a filtered list of insights, choose the link beside **Duplicate OpsItems**, **Most common titles**, or **Resources generating the most OpsItems**. To view all insights, choose **View all operational insights**.

6. Choose an insight ID to view more information.

## Resolving duplicate OpsItems based on insights

To resolve insights, you must first resolve all OpsItems associated with an insight. You can use the `AWS-BulkResolveOpsItemsForInsight` runbook to resolve OpsItems associated with an insight.

To help you resolve duplicate OpsItems and reduce the number of OpsItems created by a source, Systems Manager provides the following automation runbooks:

- The `AWS-BulkResolveOpsItems` runbook resolves OpsItems that match a specified filter.
- The `AWS-AddOpsItemDedupStringToEventBridgeRule` runbook adds a deduplication string for all OpsItem targets that are associated with a specific Amazon EventBridge rule. This runbook doesn't add a deduplication string if a rule already has one.
- The `AWS-DisableEventBridgeRule` turns off a rule in EventBridge if the rule is generating dozens or hundreds of OpsItems.

## To resolve an operational insight

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **OpsCenter**.
3. On the **Overview** tab, scroll down to **Operational insights**.
4. Choose **View all operational insights**.
5. Choose an insight ID to view more information.
6. Choose a runbook and choose **Execute**.

## Disabling operational insights

When you turn off operational insights, the system stops creating new insights and stops displaying insights in the console. Any active insights remain unchanged in the system, although you won't see them displayed in the console. If you enable this feature again, the system displays previously unresolved insights and starts creating new insights. Use the following procedure to turn off operational insights.

## To turn off operational insights

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **OpsCenter**.
3. Choose **Settings**.
4. In the **Operational insights** section, choose **Edit** and then toggle the **Disable** option.
5. Choose **Save**.

## Viewing OpsCenter logs and reports

AWS CloudTrail logs AWS Systems Manager OpsCenter API calls to the console, the AWS Command Line Interface (AWS CLI), and the SDK. You can view the information in the CloudTrail console or in an Amazon Simple Storage Service (Amazon S3) bucket. Amazon S3 uses one bucket to store all CloudTrail logs for your account.

Logs of OpsCenter actions show create, update, get, and describe OpsItem activities. For more information about viewing and using CloudTrail logs of Systems Manager activity, see [Logging AWS Systems Manager API calls with AWS CloudTrail](#).

AWS Systems Manager OpsCenter provides you with the following information about OpsItems:

- **OpsItem status summary** – Provides a summary of OpsItems by status (Open and In progress, Open, or In Progress).
- **Sources with most open OpsItems** – Provides a breakdown of the top AWS services with open OpsItems.
- **OpsItems by source and age** – Provides a count of OpsItems, grouped by source and days since creation.

## To view the OpsCenter summary report

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **OpsCenter**.
3. On the OpsItems **Overview** page, choose **Summary**.

4. Under **OpsItems by source and age**, choose the Search bar to filter OpsItems according to **Source**. Use the list to filter according to **Status**.

## Delete OpsItems

You can delete an individual OpsItem by calling the [DeleteOpsItem](#) API operation using the AWS Command Line Interface or the AWS SDK. You can't delete an OpsItem in the AWS Management Console. To delete an OpsItem, your AWS Identity and Access Management (IAM) user, group, or role must have either administrator permission or you must have been granted permission to call the `DeleteOpsItem` API operation.

### Important

Note the following important information about this operation.

- Deleting an OpsItem is irreversible. You can't restore a deleted OpsItem.
- This operation uses an *eventual consistency model*, which means the system can take a few minutes to complete this operation. If you delete an OpsItem and immediately call, for example, [GetOpsItem](#), the deleted OpsItem might still appear in the response.
- This operation is idempotent. The system doesn't throw an exception if you repeatedly call this operation for the same OpsItem. If the first call is successful, all additional calls return the same successful response as the first call.
- This operation doesn't support cross-account calls. A delegated administrator or management account can't delete OpsItems in other accounts, even if OpsCenter has been set up for cross-account administration. For more information about cross-account administration, see [\(Optional\) Setting up OpsCenter to centrally manage OpsItems across accounts](#).
- If you receive the `OpsItemLimitExceededException`, you can delete one or more OpsItems to reduce your total number of OpsItems below the quota limits. For more information about this exception, see [Troubleshooting issues with OpsCenter](#).

## Deleting an OpsItem

Use the following procedure to delete an OpsItem.

## To delete an OpsItem

1. Install and configure the AWS CLI, if you haven't already. For more information, see [Installing or updating the latest version of the AWS CLI](#).
2. Run the following command. Replace *ID* with the ID of the OpsItem you want to delete.

```
aws ssm delete-ops-item --OpsItemId ID
```

If successful, the command returns no data.

## Remediate OpsItem issues

Using AWS Systems Manager Automation runbooks, you can remediate issues with AWS resources that are identified in an OpsItem. Automation uses predefined runbooks to remediate common issues with AWS resources.

Each OpsItem includes the **Runbooks** section that provides a list of runbooks that you can use for remediation. When you choose an Automation runbook from the list, OpsCenter automatically displays some of the fields required to run the document. When you run an Automation runbook, the system associates the runbook with the related resource of the OpsItem. If Amazon EventBridge creates an OpsItem, it associates a runbook with the OpsItem. OpsCenter keeps a 30-day record of Automation runbooks for an OpsItem.

You can choose a status to view important details about the runbook, such as the reason why an automation failed and which step of the Automation runbook was running when the failure occurred, as shown in the following example.

### Latest automation results for AWS-RestartEC2Instance ✕

Dismiss
Save to operational data

The **Related resource details** page for a selected OpsItem includes the **Run automation** list. You can choose recent or resource-specific Automation runbooks and run them to remediate issues. This page also includes data providers, including Amazon CloudWatch metrics and alarms, AWS CloudTrail logs, and details from AWS Config.

You can view information about an Automation runbook by either choosing its name in the console or by using the [Systems Manager Automation runbook reference](#).

## Remediating an OpsItem using a runbook

Before you use an Automation runbook to remediate an OpsItem issue, do the following:

- Verify that you have permission to run Systems Manager Automation runbooks. For more information, see [Setting up Automation](#).
- Collect resource-specific ID information for the automation that you want to run. For example, if you want to run an automation that restarts an EC2 instance, then you must specify the ID of the EC2 instance to restart.

## To run an Automation runbook to remediate an OpsItem issue

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **OpsCenter**.

### 3. Choose the OpsItem ID to open the details page.

| ID                              | Title                   | Status | Source |
|---------------------------------|-------------------------|--------|--------|
| <a href="#">oi-a80f1dbb4464</a> | EC2 instance stopped    | Open   | EC2    |
| <a href="#">oi-0cdb512b47ed</a> | EC2 instance terminated | Open   | EC2    |
| <a href="#">oi-06f350858b55</a> | EC2 instance terminated | Open   | EC2    |

### 4. Scroll to the **Runbooks** section.

5. Use the search bar or the numbers in the upper right to find the Automation runbook that you want to run.

6. Choose a runbook, and then choose **Execute**.

7. Enter the required information for the runbook, and then choose **Submit**.

Once you start the runbook, the system returns to the previous screen and displays the status.

8. In the **Automation executions in the last 30 days** section, choose the **Execution ID** link to view steps and the status of the execution.

## Remediating an OpsItem using an associated runbook

After you run an Automation runbook from an OpsItem, OpsCenter associates the runbook with the OpsItem. An *associated* runbook is ranked higher than other runbooks in the **Runbooks** list.

Use the following procedure to run an Automation runbook that has already been associated with a related resource in an OpsItem. For information about adding related resources, see [Manage OpsItems](#).

### To run a resource-associated runbook to remediate an OpsItem issue

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **OpsCenter**.
3. Open the OpsItem.
4. In the **Related resources** section, choose the resource on which you want to run the Automation runbook.
5. Choose **Run automation**, and then choose the associated Automation runbook that you want to run.

6. Enter the required information for the runbook, and then choose **Execute**.

Once you start the runbook, the system returns to the previous screen and displays the status.

7. In the **Automation executions in the last 30 days** section, choose the **Execution ID** link to view steps and the status of the execution.

## Viewing OpsCenter summary reports

AWS Systems Manager OpsCenter includes a summary page that automatically displays the following information:

- **OpsItem status summary** – A summary of OpsItems by status, such as Open and In progress.
- **Sources with most open OpsItems** – A breakdown of the top AWS services that have open OpsItems.
- **OpsItems by source and age** – A count of OpsItems, grouped by source and number of days since creation.

### To view OpsCenter summary reports

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **OpsCenter**, and then choose the **Summary** tab.
3. In the **OpsItems by source and age** section, do the following:
  1. (Optional) In the filter field, choose **Source**, select **Equal**, **Begin With**, or **Not Equal**, and then enter a search parameter.
  2. In the adjacent list, select one of the following status values:
    - Open
    - In progress
    - Resolved
    - Open and in progress
    - All

## Troubleshooting issues with OpsCenter

This topic includes information to help you troubleshoot common errors and issues with OpsCenter.

### You receive the `OpsItemLimitExceededException`

If your AWS account has reached the maximum number of OpsItems allowed when you call the `CreateOpsItem` API operation, you receive an `OpsItemLimitExceededException`. OpsCenter returns the exception if your call would exceed the maximum number of OpsItems for either of the following quotas:

- Total number of OpsItems per AWS account per Region (including Open and Resolved OpsItems): 500,000
- Maximum number of OpsItems per AWS account per month: 10,000

These quotas apply to OpsItems created from any source except the following:

- OpsItems created by AWS Security Hub findings
- OpsItems that are auto-generated when an Incident Manager incident is opened

OpsItems created from these sources don't count against your OpsItem quotas, but you are charged for each OpsItem.

If you receive an `OpsItemLimitExceededException`, you can manually delete OpsItems until you are below the quota preventing you from creating a new OpsItem. Again, deleting OpsItems created for Security Hub findings or Incident Manager incidents won't reduce your total number of OpsItems enforced by the quotas. You must delete OpsItems from other sources. For information about how to delete an OpsItem, see [Delete OpsItems](#).

### You receive a large bill from AWS for large numbers of auto-generated OpsItems

If you configured integration with AWS Security Hub, OpsCenter creates OpsItems for Security Hub findings. Depending on the number of finding Security Hub generates and the account you were logged into when you configured integration, OpsCenter can generate large numbers of OpsItems, at a cost. Here are more specific details related to OpsItems generated by Security Hub findings:

- If you are logged into the Security Hub administrator account when you configure OpsCenter and Security Hub integration, the system creates OpsItems for findings in the administrator *and*

all member accounts. The OpsItems are all created *in the administrator account*. Depending on a variety of factors, this can lead to an unexpectedly large bill from AWS.

If you are logged into a member account when you configure integration, the system only creates OpsItems for findings in that individual account. For more information about the Security Hub administrator account, member accounts, and their relation to the EventBridge event feed for findings, see [Types of Security Hub integration with EventBridge](#) in the *AWS Security Hub User Guide*.

- For each finding that creates an OpsItem, you are charged the regular price for creating the OpsItem. You are also charged if you edit the OpsItem or if the corresponding finding is updated in Security Hub (which triggers an OpsItem update).

### **Important**

If you believe a large number of OpsItems were created in error and your AWS bill is unwarranted, contact AWS Support.

Use the following procedure if you no longer want the system to create OpsItems for Security Hub findings.

### **To stop receiving OpsItems for Security Hub findings**

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **OpsCenter**.
3. Choose **Settings**.
4. In the **Security Hub findings** section, choose **Edit**.
5. Choose the slider to change **Enabled** to **Disabled**. If you aren't able to toggle the slider, Security Hub hasn't been enabled for your AWS account.
6. Choose **Save** to save your configuration. OpsCenter no longer creates OpsItems based on Security Hub findings.

**⚠ Important**

If OpsCenter toggles the setting back to **Enabled** and continues to create OpsItems for findings, log into the Systems Manager delegated administrator account or the AWS Organizations management account and repeat this procedure. If you don't have permission to log into either of those accounts, contact your administrator and ask them to repeat this procedure to disable integration for your account.

## Using Amazon CloudWatch dashboards hosted by Systems Manager

Amazon CloudWatch dashboards are customizable home pages in the CloudWatch console that you can use to monitor your resources in a single view, even those resources that are spread across different AWS Regions. You can use CloudWatch dashboards to create customized views of the metrics and alarms for your AWS resources. With dashboards, you can create the following:

- A single view for selected metrics and alarms to help you assess the health of your resources and applications across one or more AWS Regions. You can select the color used for each metric on each graph, so that you can track the same metric across multiple graphs.
- An operational playbook that provides guidance for team members during operational events about how to respond to specific incidents.
- A common view of critical resource and application measurements that can be shared by team members for faster communication flow during operational events.

You can create dashboards by using the console, the AWS Command Line Interface (AWS CLI), or by using the CloudWatch PutDashboard API. For more information, see [Using Amazon CloudWatch dashboards](#) in the *Amazon CloudWatch User Guide*.

## AWS Systems Manager application tools

Application tools are a suite of capabilities that help you manage your applications running in AWS.

### Topics

- [AWS Systems Manager Application Manager](#)
- [AWS AppConfig](#)
- [AWS Systems Manager Parameter Store](#)

## AWS Systems Manager Application Manager

Application Manager, a capability of AWS Systems Manager, helps DevOps engineers investigate and remediate issues with their AWS resources in the context of their applications and clusters. Application Manager aggregates operations information from multiple AWS services and Systems Manager capabilities to a single AWS Management Console.

In Application Manager, an *application* is a logical group of AWS resources that you want to operate as a unit. This logical group can represent different versions of an application, ownership boundaries for operators, or developer environments, to name a few. Application Manager support for container clusters includes both Amazon Elastic Kubernetes Service (Amazon EKS) and Amazon Elastic Container Service (Amazon ECS) clusters.

When you choose **Get started** on the Application Manager home page, Application Manager automatically imports metadata about your resources that were created in other AWS services or Systems Manager capabilities. For applications, Application Manager imports metadata about all of your AWS resources organized into resource groups. Each resource group is listed in the **Custom applications** category as a unique application. Application Manager also automatically imports metadata about resources that were created by AWS CloudFormation, AWS Launch Wizard, Amazon ECS, and Amazon EKS. Application Manager then displays those resources in predefined categories.

For **Applications**, the list includes the following:

- Custom applications
- Launch Wizard
- CloudFormation stacks
- AppRegistry applications

For **Container clusters**, the list includes the following:

- Amazon ECS clusters
- Amazon EKS clusters

After import is complete, you can view operations information about your resources in these predefined categories. Or, if you want to provide more context about a collection of resources, you can manually create an application in Application Manager and move resources or groups of

resources into that application. This allows you to view operations information in the context of an application.

After you [set up](#) and configure AWS services and Systems Manager capabilities, Application Manager displays the following types of information about your resources:

- Information about the current state, status, and Amazon EC2 Auto Scaling health of the Amazon Elastic Compute Cloud (Amazon EC2) instances in your application
- Alarms provided by Amazon CloudWatch
- Compliance information provided by AWS Config and State Manager (a component of Systems Manager)
- Kubernetes cluster information provided by Amazon EKS
- Log data provided by AWS CloudTrail and Amazon CloudWatch Logs
- OpsItems provided by Systems Manager OpsCenter
- Resource details provided by the AWS services that host them.
- Container cluster information provided by Amazon ECS.

To help you remediate issues with components or resources, Application Manager also provides runbooks that you can associate with your applications. To get started with Application Manager, open the [Systems Manager console](#). In the navigation pane, choose **Application Manager**.

## What are the benefits of using Application Manager?

Application Manager reduces the time it takes for DevOps engineers to detect and investigate issues with AWS resources. To do this, Application Manager displays many types of operations information in the context of an application in one console. Application Manager also reduces the time it takes to remediate issues by providing runbooks that perform common remediation tasks on AWS resources.

## What are the features of Application Manager?

Application Manager includes the following features:

- **Import your AWS resources automatically**

During initial setup, you can choose to have Application Manager automatically import and display resources in your AWS account that are based on CloudFormation stacks, AWS Resource Groups, Launch Wizard deployments, AppRegistry applications, and Amazon ECS and Amazon

EKS clusters. The system displays these resources in predefined application or cluster categories. Thereafter, whenever new resources of these types are added to your AWS account, Application Manager automatically displays the new resources in the predefined application and cluster categories.

- **Create or edit CloudFormation stacks and templates**

Application Manager helps you provision and manage resources for your applications by integrating with [CloudFormation](#). You can create, edit, and delete AWS CloudFormation templates and stacks in Application Manager. Application Manager also includes a template library where you can clone, create, and store templates. Application Manager and CloudFormation display the same information about the current status of a stack. Templates and template updates are stored in Systems Manager until you provision the stack, at which time the changes are also displayed in CloudFormation.

- **View information about your instances in the context of an application**

Application Manager integrates with Amazon Elastic Compute Cloud (Amazon EC2) to display information about your instances in the context of an application. Application Manager displays instance state, status, and Amazon EC2 Auto Scaling health for a selected application in a graphical format. The **Instances** tab also includes a table with the following information for each instance in your application.

- Instance state (Pending, Stopping, Running, Stopped)
- Ping status for SSM Agent
- Status and name of the last Systems Manager Automation runbook processed on the instance
- A count of Amazon CloudWatch Logs alarms per state.
  - ALARM – The metric or expression is outside of the defined threshold.
  - OK – The metric or expression is within the defined threshold.
  - INSUFFICIENT\_DATA – The alarm has just started, the metric is not available, or not enough data is available for the metric to determine the alarm state.
- Auto Scaling group health for the parent and individual autoscaling groups

- **View operational metrics and alarms for an application or cluster**

Application Manager integrates with [Amazon CloudWatch](#) to provide real-time operational metrics and alarms for an application or cluster. You can drill down into your application tree to view alarms at each component level, or view alarms for an individual cluster.

- **View log data for an application**

Application Manager integrates with [Amazon CloudWatch Logs](#) to provide log data in the context of your application without having to leave Systems Manager.

- **View and manage OpsItems for an application or cluster**

Application Manager integrates with [AWS Systems Manager OpsCenter](#) to provide a list of operational work items (OpsItems) for your applications and clusters. The list reflects automatically generated and manually created OpsItems. You can view details about the resource that created an OpsItem and the OpsItem status, source, and severity.

- **View resource compliance data for an application or cluster**

Application Manager integrates with [AWS Config](#) to provide compliance and history details about your AWS resources according to rules you specify. Application Manager also integrates with [AWS Systems Manager State Manager](#) to provide compliance information about the state you want to maintain for your Amazon Elastic Compute Cloud (Amazon EC2) instances.

- **View Amazon ECS and Amazon EKS cluster infrastructure information**

Application Manager integrates with [Amazon ECS](#) and [Amazon EKS](#) to provide information about the health of your cluster infrastructures and a component runtime view of the compute, networking, and storage resources in a cluster.

However, you can't manage or view operations information about your Amazon EKS pods or containers in Application Manager. You can only manage and view operations information about the infrastructure that is hosting your Amazon EKS resources.

- **View resource cost details for an application**

Application Manager is integrated with AWS Cost Explorer, a feature of AWS Billing and Cost Management, through the **Cost** widget. After you enable Cost Explorer in the Billing and Cost Management console, the **Cost** widget in Application Manager shows cost data for a specific non-container application or application component. You can use filters in the widget to view cost data according to different time periods, granularities, and cost types in either a bar or line chart.

- **View detailed resource information in one console**

Choose a resource name listed in Application Manager and view contextual information and operations information about that resource without having to leave Systems Manager.

- **Receive automatic resource updates for applications**

If you make changes to a resource in a service console, and that resource is part of an application in Application Manager, then Systems Manager automatically displays those changes. For example, if you update a stack in the AWS CloudFormation console, and if that stack is part of an Application Manager application, then the stack updates are automatically reflected in Application Manager.

- **Discover Launch Wizard applications automatically**

Application Manager is integrated with [AWS Launch Wizard](#). If you used Launch Wizard to deploy resources for an application, Application Manager can automatically import and display them in a Launch Wizard section.

- **Monitor application resources in Application Manager by using CloudWatch Application Insights**

Application Manager integrates with Amazon CloudWatch Application Insights. Application Insights identifies and sets up key metrics, logs, and alarms across your application resources and technology stack. Application Insights continuously monitors metrics and logs to detect and correlate anomalies and errors. When the system detects errors or anomalies, Application Insights generates CloudWatch Events that you can use to set up notifications or take actions. You can enable and view Application Insights on the **Overview** and **Monitoring** tabs in Application Manager. For more information about Application Insights, see [What is Amazon CloudWatch Application Insights](#) in the *Amazon CloudWatch User Guide*.

- **Remediate issues with runbooks**

Application Manager includes predefined Systems Manager runbooks for remediating common issues with AWS resources. You can execute a runbook against all of the applicable resources in an application without having to leave Application Manager.

## Is there a charge to use Application Manager?

Application Manager is available at no additional charge.

## What are the resource quotas for Application Manager?

You can view quotas for all Systems Manager capabilities in the [Systems Manager service quotas](#) in the *Amazon Web Services General Reference*. Unless otherwise noted, each quota is Region specific.

## Topics

- [Setting up related services](#)
- [Configuring permissions for Systems Manager Application Manager](#)
- [Adding applications and container clusters to Application Manager](#)
- [Working with applications](#)

## Setting up related services

Application Manager, a capability of AWS Systems Manager, displays resources and information from other AWS services and Systems Manager capabilities. To maximize the amount of operations information displayed in Application Manager, we recommend that you set up and configure these other services or capabilities *before* you use Application Manager.

### Topics

- [Set up tasks for importing resources](#)
- [Set up tasks for viewing operations information about resources](#)

### Set up tasks for importing resources

The following setup tasks help you view AWS resources in Application Manager. After each of these tasks is completed, Systems Manager can automatically import resources into Application Manager. After your resources are imported, you can create applications in Application Manager and move your imported resources into them. This helps you view operations information in the context of an application.

### (Optional) Organize your AWS resources by using tags

You can assign metadata to your AWS resources in the form of tags. Each tag is a label consisting of a user-defined key and value. Tags can help you manage, identify, organize, search for, and filter resources. You can create tags to categorize resources by purpose, owner, environment, or other criteria.

### (Optional) Organizes your AWS resources by using [AWS Resource Groups](#)

You can use resource groups to organize your AWS resources. Resource groups make it easier to manage, monitor, and automate tasks on many resources at one time.

Application Manager automatically imports all of your resource groups and lists them in the **Custom applications** category.

## **(Optional) Set up and deploy your AWS resources by using [AWS CloudFormation](#)**

AWS CloudFormation allows you to create and provision AWS infrastructure deployments predictably and repeatedly. It helps you use AWS services such as Amazon EC2, Amazon Elastic Block Store (Amazon EBS), Amazon Simple Notification Service (Amazon SNS), Elastic Load Balancing, and AWS Auto Scaling. With CloudFormation, you can build reliable, scalable, cost-effective applications in the cloud without worrying about creating and configuring the underlying AWS infrastructure.

Application Manager automatically imports all of your AWS CloudFormation resources and lists them in the **AWS CloudFormation stacks** category. You can create CloudFormation stacks and templates in Application Manager. Stack and template changes are automatically synchronized between Application Manager and CloudFormation. You can also create applications in Application Manager and move stacks into them. This helps you view operations information for resources in your stacks in the context of an application. For pricing information, see [AWS CloudFormation Pricing](#).

## **(Optional) Set up and deploy your applications by using AWS Launch Wizard**

Launch Wizard guides you through the process of sizing, configuring, and deploying AWS resources for third-party applications without the need to manually identify and provision individual AWS resources.

Application Manager automatically imports all of your Launch Wizard resources and lists them in the **Launch Wizard** category. For more information about AWS Launch Wizard, see [Getting started with AWS Launch Wizard for SQL Server](#). Launch Wizard is available at no additional charge. You only pay for the AWS resources that you provision to run your solution.

## **(Optional) Set up and deploy your containerized applications by using [Amazon ECS](#) and [Amazon EKS](#)**

Amazon Elastic Container Service (Amazon ECS) is a highly scalable, fast container management service that makes it easy to run, stop, and manage containers on a cluster. Your containers are defined in a task definition that you use to run individual tasks or tasks within a service.

Amazon EKS is a managed service that helps you to run Kubernetes on AWS without needing to install, operate, and maintain your own Kubernetes control plane or nodes. Kubernetes is an open-source system for automating the deployment, scaling, and management of containerized applications.

Application Manager automatically imports all of your Amazon ECS and Amazon EKS infrastructure resources and lists them on the **Container clusters** tab. However, you can't manage or view operations information about your Amazon EKS pods or containers in Application Manager. You can only manage and view operations information about the infrastructure that is hosting your Amazon EKS resources. For pricing information, see [Amazon ECS Pricing](#) and [Amazon EKS Pricing](#).

## Set up tasks for viewing operations information about resources

The following setup tasks help you view operations information about your AWS resources in Application Manager.

### (Recommended) Verify [runbook permissions](#)

You can remediate issues with AWS resources from Application Manager by using Systems Manager Automation runbooks. To use this remediation capability, you must configure or verify permissions. For pricing information, see [AWS Systems Manager Pricing](#).

### (Optional) Enable [Cost Explorer](#)

AWS Cost Explorer is a feature of AWS Cost Management that you can use to visualize your cost data for further analysis. When you enable Cost Explorer, you can view cost information, cost history, and cost optimization for your application's resources in the Application Manager console.

### (Optional) Set up and configure Amazon CloudWatch [logs](#) and [alarms](#)

CloudWatch is a monitoring and management service that provides data and actionable insights for AWS, hybrid, and multicloud applications and infrastructure resources. With CloudWatch, you can collect and access all your performance and operational data in the form of logs and metrics from a single platform. To view CloudWatch logs and alarms for your resources in Application Manager, you must set up and configure CloudWatch. For pricing information, see [CloudWatch Pricing](#).

#### **Note**

CloudWatch Logs support applies to applications only, not to clusters.

## (Optional) Set up and configure [AWS Config](#)

AWS Config provides a detailed view of the resources associated with your AWS account, including how they're configured, how they're related to one another, and how the configurations and their relationships have changed over time. You can use AWS Config to evaluate the configuration settings of your AWS resources. You do this by creating AWS Config rules, which represent your ideal configuration settings. While AWS Config continually tracks the configuration changes that occur among your resources, it checks whether these changes violate any of the conditions in your rules. If a resource violates a rule, AWS Config flags the resource and the rule as *noncompliant*. Application Manager displays compliance information about AWS Config rules. To view this data in Application Manager, you must set up and configure AWS Config. For pricing information, see [AWS Config Pricing](#).

## (Optional) Create State Manager [associations](#)

You can use Systems Manager State Manager to create a configuration that you assign to your managed nodes. The configuration, called an *association*, defines the state that you want to maintain on your nodes. To view association compliance data in Application Manager, you must configure one or more State Manager associations. State Manager is offered at no additional charge.

## (Optional) Set up and configure [OpsCenter](#)

You can view operational work items (OpsItems) about your resources in Application Manager by using OpsCenter. You can configure Amazon CloudWatch and Amazon EventBridge to automatically send OpsItems to OpsCenter based on alarms and events. You can also enter OpsItems manually. For pricing information, see [AWS Systems Manager Pricing](#).

## Configuring permissions for Systems Manager Application Manager

You can use all features of Application Manager, a capability of AWS Systems Manager, if your AWS Identity and Access Management (IAM) entity (such as a user, group, or role) has access to the API operations listed in this topic. The API operations are separated into two tables to help you understand the different functions they perform.

The following table lists the API operations that Systems Manager calls if you choose a resource in Application Manager because you want to view the resource details. For example, if Application Manager lists an Amazon EC2 Auto Scaling group, and if you choose that group to view its details, then Systems Manager calls the `autoscaling:DescribeAutoScalingGroups` API operations.

If you don't have any Auto Scaling groups in your account, this API operation isn't called from Application Manager.

### Note

You can restrict a user's ability to make changes to applications and resources in Application Manager by removing the following API operations from the IAM permissions policy attached to their user, group, or role. Removing these actions creates a read-only experience in Application Manager. The following are all of the APIs that allow users to make changes to the application or any other related resources.

```

applicationinsights:CreateApplication
ce:UpdateCostAllocationTagsStatus
cloudformation:CreateStack
cloudformation>DeleteStack
cloudformation:UpdateStack
cloudwatch:DisableAlarmActions
cloudwatch:EnableAlarmActions
cloudwatch:PutMetricAlarm
config:PutRemediationConfigurations
config:StartConfigRulesEvaluation
config:StartRemediationExecution
ecs:TagResource
eks:TagResource
iam:CreateServiceLinkedRole
resource-groups:CreateGroup
resource-groups>DeleteGroup
resource-groups:Tag
resource-groups:Untag
resource-groups:UpdateGroup
sns:CreateTopic
sns:Subscribe
ssm:AddTagsToResource
ssm:CreateDocument
ssm:CreateOpsMetadata

```

```
ssm:DeleteDocument
ssm:DeleteOpsMetadata
ssm:ModifyDocumentPermission
ssm:RemoveTagsFromResource
ssm:StartAssociationsOnce
ssm:StartAutomationExecution
ssm:UpdateDocument
ssm:UpdateDocumentDefaultVersion
ssm:UpdateOpsMetadata
ssm:UpdateOpsItem
ssm:UpdateServiceSetting
tag:TagResources
tag:UntagResources
```

For information about creating and editing IAM policies, see [Creating IAM Policies](#) in the *IAM User Guide*. For information about how to assign this policy to an IAM entity (such as a user, group, or role), see [Adding and removing IAM identity permissions](#).

## Adding applications and container clusters to Application Manager

Application Manager is a component of AWS Systems Manager. In Application Manager, an *application* is a logical group of AWS resources that you want to operate as a unit. This logical group can represent different versions of an application, ownership boundaries for operators, or developer environments, to name a few.

When you choose **Get started** on the Application Manager home page, Application Manager automatically imports metadata about your resources that were created in other AWS services or Systems Manager capabilities. For applications, Application Manager imports metadata about all of your AWS resources organized into resource groups. Each resource group is listed in the **Custom applications** category as a unique application. Application Manager also automatically imports metadata about resources that were created by AWS CloudFormation, AWS Launch Wizard, Amazon Elastic Container Service (Amazon ECS), and Amazon Elastic Kubernetes Service (Amazon EKS). Application Manager then displays those resources in predefined categories.

For **Applications**, the list includes the following:

- Custom applications
- Launch Wizard
- CloudFormation stacks

- AppRegistry applications

For **Container clusters**, the list includes the following:

- Amazon ECS clusters
- Amazon EKS clusters

After import is complete, you can view operations information for an application or a specific resource in these predefined categories. Or, if you want to provide more context about a collection of resources, you can manually create an application in Application Manager. You can then add resources or groups of resources into that application. After you create an application in Application Manager, you can view operations information about your resource in the context of an application.

### Creating an application in Application Manager

Use the following procedure to create an application in Application Manager and add resources to that application.

#### To create an application in Application Manager

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Application Manager**.
3. Choose the **Applications** tab, and then choose **Create application**.
4. For **Application name**, enter a name to help you understand the purpose of the resources that will be added to this application.
5. For **Application description**, enter information about this application.
6. In the **Choose application components** section, use the options provided to choose resources for this application. You can add a combination of tagged resources, resource groups, and stacks to an application. You must choose a minimum of two components and a maximum of 15. If you choose resources by using tags, then all resources assigned those tags will be listed on the **Resources** tab after you add the new application. This is also true for resources included in a resource group or in a stack.

If you don't see the resources you want to add to the application, then verify the resources have been tagged properly, added to an AWS Resource Groups group, or added to an AWS CloudFormation stack.

7. For **Application tags - optional**, specify tags for this application.
8. Choose **Create**.

Application Manager creates the application and opens it. The **Components** tree lists the new application as the top-level component and the resources, groups, or stacks you selected as subcomponents. The next time you open Application Manager, you can find the new application in the **Custom applications** category.

## Working with applications

Application Manager is a component of AWS Systems Manager. This section includes topics to help you work with Application Manager applications and view operations information about your AWS resources.

### Contents

- [Application overview in Application Manager](#)
- [Managing your application EC2 instances](#)
- [Viewing resources associated with your application](#)
- [Managing your application compliance](#)
- [Using CloudWatch Application Insights to monitor an application](#)
- [Viewing OpsItems for an application](#)
- [Managing your application logs](#)
- [Use Automation runbooks to remediate application issues](#)
- [Tag resources in Application Manager](#)
- [Working with AWS CloudFormation templates and stacks in Application Manager](#)
- [Working with clusters in Application Manager](#)

### Application overview in Application Manager

In Application Manager, a component of AWS Systems Manager, the **Overview** tab displays a summary of Amazon CloudWatch alarms, operational work items (OpsItems), CloudWatch

Application Insights, and runbook history. Choose **View all** for any card to open the corresponding tab where you can view all application insights, alarms, OpsItems, or runbook history.

## About Application Insights

CloudWatch Application Insights identifies and sets up key metrics, logs, and alarms across your application resources and technology stack. Application Insights continuously monitors metrics and logs to detect and correlate anomalies and errors. When the system detects errors or anomalies, Application Insights generates CloudWatch Events that you can use to set up notifications or take actions. If you choose the **Edit configuration** button on the **Monitoring** tab, the system opens the CloudWatch Application Insights console. For more information about Application Insights, see [What is Amazon CloudWatch Application Insights](#) in the *Amazon CloudWatch User Guide*.

## About Cost Explorer

Application Manager is integrated with AWS Cost Explorer, a feature of [AWS Cost Management](#), through the **Cost** widget and **Cost** tab. After you enable Cost Explorer in the Cost Management console, the **Cost** widget and **Cost** tab in Application Manager shows cost data for a specific non-container application or application component. You can use filters in the widget, or tab, to view cost data according to different time periods, levels of granularity, and cost types in either a bar or line chart.

You can enable this feature by choosing the **Go to AWS Cost Management console** button. By default, the data is filtered to the past three months. For a non-container application, if you choose the **View all** button, Application Manager opens the **Resources** tab. For container applications, the **View all** button opens the AWS Cost Explorer console.

## Actions you can perform on this page

You can turn on and access information about the following widgets on the **Overview** tab on this page. When a widget is enabled, choose its **View all** to see relevant application details for that area.

- In the **Insights and Alarms** section, choose the number for a severity to open the **Monitoring**, tab, where you can view more details about alarms of the chosen severity.
- In the **Cost** section, choose **View all** to open the **Resources** tab, where you can view cost data for a specific application or application component.
- In the **Compliance** section, choose **View all** to open the **Compliance** tab, where you can view compliance information from AWS Config and State Manager associations.

**Note**

To view patch compliance details, choose the **Compliance** tab directly. Then you can view patch compliance details for the managed nodes used by the selected application.

- In the **Runbooks** section, choose a runbook to open it in the Systems Manager **Documents** page where you can view more details about the document.
- In the **OpsItems** section, choose a severity to open the **OpsItems** tab where you can view all OpsItems of the chosen severity.
- Choose a **View all** button to open the corresponding tab. You can view all alarms, OpsItems, or runbook history entries for the application.

**To open the Overview tab**

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Application Manager**.
3. In the **Applications** section, choose a category. If you want to open an application you created manually in Application Manager, choose **Custom applications**.
4. Choose the application in the list. Application Manager opens the **Overview** tab.

**Managing your application EC2 instances**

Application Manager integrates with Amazon Elastic Compute Cloud (Amazon EC2) to display information about your instances in the context of an application. Application Manager displays instance state, status, and Amazon EC2 Auto Scaling health for a selected application in a graphical format. The **Instances** tab also includes a table with the following information for each instance in your application:

- Instance state (Pending, Stopping, Running, Stopped)
- Ping status for SSM Agent
- Status and name of the most recent Systems Manager Automation runbook processed on the instance
- A count of Amazon CloudWatch Logs alarms per state.
  - ALARM – The metric or expression is outside of the defined threshold.

- **OK** – The metric or expression is within the defined threshold.
- **INSUFFICIENT\_DATA** – The alarm has just started, the metric is not available, or not enough data is available for the metric to determine the alarm state.
- Auto Scaling group health for the parent and individual autoscaling groups

If you choose an instance in the **All instances** table, Application Manager displays information about that instance on four tabs:

- **Details** – All of the instance details from Amazon EC2, including the Amazon Machine Image (AMI), DNS information, IP address information, and more.
- **Health** – The current status as provided by EC2 system and instance status checks.
- **Execution history** – Execution logs for Systems Manager Automation runbooks and API calls processed by the instance.
- **CloudWatch alarms** – The name, state, and more for any CloudWatch alarms raised by the instance.

### Actions you can perform on this page

You can perform the following actions on this page:

- Start, stop, and terminate instances.
- Apply a Chef recipe.
- Attach instances to, or detach instances from, an Auto Scaling group.
- Enable automated updates for SSM Agent.

### To open the Instances tab

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Application Manager**.
3. In the **Applications** section, choose a category. If you want to open an application that you created manually in Application Manager, choose **Custom applications**.
4. Choose the application in the list. Application Manager opens the **Overview** tab.
5. Choose the **Instances** tab.

## To view details for your application instances

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Application Manager**.
3. In the **Applications** section, choose a category. If you want to open an application that you created manually in Application Manager, choose **Custom applications**.
4. Choose the application in the list. Application Manager opens the **Overview** tab.
5. Choose the **Instances** tab.
6. Select the button next to the instance whose details you want to view.
7. Review the instance details at the bottom of the page.

## To automatically update SSM Agent

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Application Manager**.
3. In the **Applications** section, choose a category. If you want to open an application that you created manually in Application Manager, choose **Custom applications**.
4. Choose the application in the list. Application Manager opens the **Overview** tab.
5. Choose the **Instances** tab.
6. In the **Agent actions** dropdown, choose **Configure SSM Agent update**.
7. Choose **All instances** to configure automatic SSM Agent updates for all managed instances. Alternatively, choose **Instance** to configure automation SSM Agent updates for a single instance in your application.
8. Select the **Enable automatic update** toggle.
9. In the **Specify schedule** dropdown, choose the schedule you want to use for SSM Agent updates.
10. Select **Configure**.

## Viewing resources associated with your application

In Application Manager, a component of AWS Systems Manager, the **Resources** tab displays the AWS resources in your application. If you choose a top-level component, this page displays all

resources for that component and any subcomponents. If you choose a subcomponent, this page shows only the resources assigned to that subcomponent.

### Actions you can perform on this page

You can perform the following actions on this page:

- Choose a resource name to view information about it, including details provided by the console where it was created, tags, Amazon CloudWatch alarms, AWS Config details, and AWS CloudTrail log information.
- Choose the option button beside a resource name. Then, choose the **Resource timeline** button to open the AWS Config console where you can view compliance information about a selected resource.
- If you enabled AWS Cost Explorer, the **Cost Explorer** section shows cost data for a specific non-container application or application component. You can enable this feature by choosing the **Go to AWS Cost Management console** button. Use the filters in this section to view cost information about your application.

### To open the Resources tab

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Application Manager**.
3. In the **Applications** section, choose a category. If you want to open an application you created manually in Application Manager, choose **Custom applications**.
4. Choose the application in the list. Application Manager opens the **Overview** tab.
5. Choose the **Resources** tab.

### Managing your application compliance

In Application Manager, a component of AWS Systems Manager, the **Configurations** page displays [AWS Config](#) resource and configuration rule compliance information. This page also displays AWS Systems Manager [State Manager](#) association compliance information. You can choose a resource, a rule, or an association to open the corresponding console for more information. This page displays compliance information from the last 90 days.

### Actions you can perform on this page

You can perform the following actions on this page:

- Choose a resource name to open the AWS Config console where you can view compliance information about a selected resource.
- Choose the option button beside a resource name. Then, choose the **Resource timeline** button to open the AWS Config console where you can view compliance information about a selected resource.
- In the **Config rules compliance** section, you can do the following:
  - Choose a rule name to open the AWS Config console where you can view information about that rule.
  - Choose **Add rules** to open the AWS Config console where you can create a rule.
  - Choose the option button beside a rule name, choose **Actions**, and then choose **Manage remediation** to change the remediation action for a rule.
  - Choose the option button beside a rule name, choose **Actions**, and then choose **Re-evaluate** to have AWS Config run a compliance check on the selected rule.
- In the **Association compliance** section, you can do the following:
  - Choose an association name to open the **Associations** page where you can view information about that association.
  - Choose **Create association** to open Systems Manager State Manager where you can create an association.
  - Choose the option button beside an association name and choose **Apply association** to immediately start all actions specified in the association.

### To open the Compliance tab

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Application Manager**.
3. In the **Applications** section, choose a category. If you want to open an application you created manually in Application Manager, choose **Custom applications**.
4. Choose the application in the list. Application Manager opens the **Overview** tab.
5. Choose the **Compliance** tab.

## Using CloudWatch Application Insights to monitor an application

In Application Manager, a component of AWS Systems Manager, the **Monitoring** tab displays Amazon CloudWatch Application Insights and alarm details for resources in an application.

### About Application Insights

CloudWatch Application Insights identifies and sets up key metrics, logs, and alarms across your application resources and technology stack. Application Insights continuously monitors metrics and logs to detect and correlate anomalies and errors. When the system detects errors or anomalies, Application Insights generates CloudWatch Events that you can use to set up notifications or take actions. If you choose the **Edit configuration** button on the **Monitoring** tab, the system opens the CloudWatch Application Insights console. For more information about Application Insights, see [What is Amazon CloudWatch Application Insights](#) in the *Amazon CloudWatch User Guide*.

### Actions you can perform on this page

You can perform the following actions on this page:

- Choose a service name in the **Alarms by AWS service** section to open CloudWatch to the selected service and alarm.
- Adjust the time period for data displayed in widgets in the **Recent alarms** section by selecting one of the predefined time period values. You can choose **custom** to define your own time period.

- Hover your cursor over a widget in the **Recent alarms** section to view a data pop-up for a specific time.

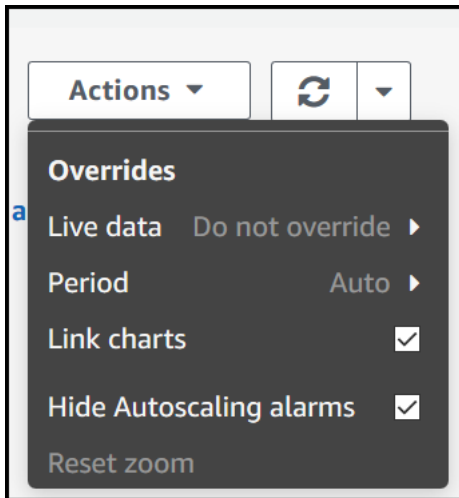

- Choose the options menu in a widget to view display options. Choose **Enlarge** to expand a widget. Choose **Refresh** to update the data in a widget. Click and drag your cursor in a widget data display to select a specific range. You can then choose **Apply time range**.

- Choose the **Actions** menu to view alarm data **Override** options, which include the following:
  - Choose whether your widget displays live data. Live data is data published within the last minute that hasn't been fully aggregated. If live data is turned off, only data points with an aggregation period of at least one minute in the past are shown. For example, when using 5-minute periods, the data point for 12:35 would be aggregated from 12:35 to 12:40, and displayed at 12:41.

If live data is turned on, the most recent data point is shown as soon as any data is published in the corresponding aggregation interval. Each time you refresh the display, the most recent data point might change as new data within that aggregation period is published.

- Specify a time period for live data.
- Link the charts in the **Recent alarms** section, so that when you zoom in or zoom out on one chart, the other chart zooms in or zooms out at the same time. You can unlink charts to limit zoom to one chart.
- Hide Auto Scaling alarms.

## To open the Monitoring tab

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Application Manager**.
3. In the **Applications** section, choose a category. If you want to open an application you created manually in Application Manager, choose **Custom applications**.
4. Choose the application in the list. Application Manager opens the **Overview** tab.
5. Choose the **Monitoring** tab.

## Viewing OpsItems for an application

In Application Manager, a component of AWS Systems Manager, the **OpsItems** tab displays operational work items (OpsItems) for resources in the selected application. You can configure

Systems Manager OpsCenter to automatically create OpsItems from Amazon CloudWatch alarms and Amazon EventBridge events. You can also manually create OpsItems.

### Actions you can perform on this tab

You can perform the following actions on this page:

- Filter the list of OpsItems by using the search field. You can filter by OpsItem name, ID, source ID, or severity. You can also filter the list based on status. OpsItems support the following statuses: Open, In progress, Open and In progress, Resolved, or All.
- Change the status of an OpsItem by choosing the option button beside it and then choosing an option in the **Set status** menu.
- Open Systems Manager OpsCenter to create an OpsItem by choosing **Create OpsItem**.

### To open the OpsItems tab

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Application Manager**.
3. In the **Applications** section, choose a category. If you want to open an application you created manually in Application Manager, choose **Custom applications**.
4. Choose the application in the list. Application Manager opens the **Overview** tab.
5. Choose the **OpsItems** tab.

### Managing your application logs

In Application Manager, a component of AWS Systems Manager, the **Logs** tab displays a list of log groups from Amazon CloudWatch Logs.

### Actions you can perform on this tab

You can perform the following actions on this page:

- Choose a log group name to open it in CloudWatch Logs. You can then choose a log stream to view logs for a resource in the context of an application.
- Choose **Create log groups** to create a log group in CloudWatch Logs.

## To open the Logs tab

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Application Manager**.
3. In the **Applications** section, choose a category. If you want to open an application you created manually in Application Manager, choose **Custom applications**.
4. Choose the application in the list. Application Manager opens the **Overview** tab.
5. Choose the **Logs** tab.

## Use Automation runbooks to remediate application issues

You can remediate issues with AWS resources from Application Manager, a capability of AWS Systems Manager, by using Automation runbooks. An Automation runbook defines the actions that Systems Manager performs on your managed instances and other AWS resources when an automation runs. Automation is a capability of AWS Systems Manager. A runbook contains one or more steps that run in sequential order. Each step is built around a single action. Output from one step can be used as input in a later step.

When you choose **Start runbook** from an Application Manager application or cluster, the system displays a filtered list of available runbooks based on the type of resources in your application or cluster. When you choose the runbook you want to start, Systems Manager opens the **Execute automation document** page.

Application Manager includes the following enhancements for working with runbooks.

- If you choose the name of a resource in Application Manager and then choose **Execute runbook**, the system displays a filtered list of runbooks for that resource type.
- You can initiate an automation on all resources of the same type by choosing a runbook in the list and then choosing **Run for resources of same type**.

## Before you begin

Before you start a runbook from Application Manager, do the following:

- Verify that you have the correct permissions for starting runbooks. For more information, see [Setting up Automation](#).

- Review the Automation procedure documentation about starting runbooks. For more information, see [Run an automated operation powered by Systems Manager Automation](#).

## To start a runbook from Application Manager

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Application Manager**.
3. In the **Applications** section, choose a category. If you want to open an application you created manually in Application Manager, choose **Custom applications**.
4. Choose the application in the list. Application Manager opens the **Overview** tab.
5. Choose **Start runbook**. Application Manager opens the **Automation widget** pop up. For information about the options in the **Automation widget**, see [Run an automated operation powered by Systems Manager Automation](#).

## Tag resources in Application Manager

You can quickly add or delete tags on applications and AWS resources in Application Manager. Use the following procedure to add a tag to or delete a tag from an application and all AWS resources in that application.

### To add a tag to or delete a tag from an application and all resources in the application

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Application Manager**.
3. In the **Applications** section, choose a category. If you want to open an application you created manually in Application Manager, choose **Custom applications**.
4. Choose the application in the list. Application Manager opens the **Overview** tab.
5. In the **Application information** section, choose the number beneath **Application tags**. If no tags are assigned to the application, the number is zero.
6. To add a tag, choose **Add new tag**. Specify a key and an optional value. To delete a tag, choose **Remove**.
7. Choose **Save**.

Use the following procedure to add a tag to or delete a tag from a specific resource in Application Manager.

### To add a tag to or delete a tag from a resource

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Application Manager**.
3. In the **Applications** section, choose a category. If you want to open an application you created manually in Application Manager, choose **Custom applications**.
4. Choose the application in the list. Application Manager opens the **Overview** tab.
5. Choose the **Resources** tab.
6. Choose a resource name.
7. In the **Tags** section choose **Edit**.
8. To add a tag, choose **Add new tag**. Specify a key and an optional value. To delete a tag, choose **Remove**.
9. Choose **Save**.

### Working with AWS CloudFormation templates and stacks in Application Manager

Application Manager, a capability of AWS Systems Manager, helps you provision and manage resources for your applications by integrating with AWS CloudFormation. You can create, edit, and delete AWS CloudFormation templates and stacks in Application Manager. A *stack* is a collection of AWS resources that you can manage as a single unit. This means you can create, update, or delete a collection of AWS resources by using CloudFormation stacks. A *template* is a formatted text file in JSON or YAML that specifies the resources you want to provision in your stacks.

Application Manager also includes a template library where you can clone, create, and store templates. Application Manager and CloudFormation display the same information about the current status of a stack. Templates and template updates are stored in Systems Manager until you provision the stack, at which time the changes are also displayed in CloudFormation.

After you create a stack in Application Manager, the **CloudFormation stacks** page displays helpful information about it. This includes the template used to create it, a count of [OpsItems](#) for resources in your stack, the [stack status](#), and [drift status](#).

### About Cost Explorer

Application Manager is integrated with AWS Cost Explorer, a feature of [AWS Cost Management](#), through the **Cost** widget. After you enable Cost Explorer in the Cost Management console, the **Cost** widget in Application Manager shows cost data for a specific non-container application or application component. You can use filters in the widget to view cost data according to different time periods, granularities, and cost types in either a bar or line chart.

You can enable this feature by choosing the **Go to AWS Cost Management console** button. By default, the data is filtered to the past three months. For a non-container application, if you choose the **View all** button, Application Manager opens the **Resources** tab. For container applications, the **View all** button opens the AWS Cost Explorer console.

### Note

Cost Explorer uses tags to track your application costs. If your AWS CloudFormation stack-based application isn't configured with the `AppManager:CFNStackKey` tag key, Cost Explorer fails to present accurate cost data in Application Manager. When the `AppManager:CFNStackKey` tag key is not detected, you will be prompted in the console to add the tag to your CloudFormation stack to enable cost tracking. Adding it maps the tag key to the Amazon Resource Name (ARN) of your stack and enables the **Cost** widget to display accurate cost data.

### Important

Adding the `AppManager:CFNStackKey` tag will trigger a stack update. Any manual configurations that were performed after the stack was originally deployed will not be reflected after the user tag is added. For more information about resource update behaviors, see [Update behaviors of stack resources](#) in the *AWS CloudFormation User Guide*

## Before you begin

Use the following links to learn about CloudFormation concepts before you create, edit, or delete CloudFormation templates and stacks by using Application Manager.

- [What is AWS CloudFormation?](#)
- [AWS CloudFormation best practices](#)
- [Learn template basics](#)

- [Working with AWS CloudFormation stacks](#)
- [Working with AWS CloudFormation templates](#)
- [Sample templates](#)

## Topics

- [Using Application Manager to manage AWS CloudFormation templates](#)
- [Using Application Manager to manage AWS CloudFormation stacks](#)

## Using Application Manager to manage AWS CloudFormation templates

Application Manager, a capability of AWS Systems Manager, includes a template library and other tools to help you manage AWS CloudFormation templates. This section includes the following information.

## Topics

- [Working with the template library](#)
- [Creating a template](#)
- [Editing a template](#)

## Working with the template library

The Application Manager template library provides tools to help you view, create, edit, delete, and clone templates. You can also provision stacks directly from the template library. Templates are stored as Systems Manager (SSM) documents of type `CloudFormation`. By storing templates as SSM documents, you can use version controls to work with different versions of a template. You can also set permissions and share templates. After you successfully provision a stack, the stack and template are available in Application Manager and CloudFormation.

## Before you begin

We recommend that you read the following topics to learn more about SSM documents before you start working with CloudFormation templates in Application Manager.

- [AWS Systems Manager Documents](#)
- [Sharing SSM documents](#)

- [Best practices for shared SSM documents](#)

## To view the template library in Application Manager

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Application Manager**.
3. In the **Applications** section, choose **CloudFormation stacks**.
4. Choose **Template library**.

## Creating a template

The following procedure describes how to create a CloudFormation template in Application Manager. When you create a template, you enter the stack details of the template in either JSON or YAML. If you're unfamiliar with JSON or YAML, you can use AWS CloudFormation Designer, a tool for visually creating and modifying templates. For more information, see [What is AWS CloudFormation Designer?](#) in the *AWS CloudFormation User Guide*. For information about the structure and syntax of a template, see [Template anatomy](#).

You can also construct a template from multiple template snippets. Template snippets are examples that demonstrate how to write templates for a particular resource. For example, you can view snippets for Amazon Elastic Compute Cloud (Amazon EC2) instances, Amazon Simple Storage Service (Amazon S3) domains, AWS CloudFormation mappings, and more. Snippets are grouped by resource. You can find general-purpose AWS CloudFormation snippets in the [General template snippets](#) section of the *AWS CloudFormation User Guide*.

## Creating a CloudFormation template in Application Manager (console)

Use the following procedure to create a CloudFormation template in Application Manager by using the AWS Management Console.

### To create a CloudFormation template in Application Manager

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Application Manager**.
3. In the **Applications** section, choose **CloudFormation stacks**.

4. Choose **Template library**, and then either choose **Create template** or choose an existing template and then choose **Actions, Clone**.
5. For **Name**, enter a name for the template that helps you identify the resources it creates or the purpose of the stack.
6. (Optional) For **Version name**, enter a name or a number to identify the template version.
7. (Optional) For **Description**, enter information about this template.
8. In the **Code editor** section, choose either **YAML** or **JSON** and then either enter or copy and paste your template code.
9. (Optional) In the **Tags** section, apply one or more tag key name/value pairs to the template.
10. (Optional) In the **Permissions** section, enter an AWS account ID and choose **Add account**. This action provides read permission to the template. The account owner can provision and clone the template, but they can't edit or delete it.
11. Choose **Create**. The template is saved in the Systems Manager (SSM) Document service.

## Creating a CloudFormation template in Application Manager (command line)

After you create the content of your CloudFormation template in JSON or YAML, you can use the AWS Command Line Interface (AWS CLI) or AWS Tools for PowerShell to save the template as an SSM document. Replace each *example resource placeholder* with your own information.

### Before you begin

Install and configure the AWS CLI or the AWS Tools for PowerShell, if you have not already. For information, see [Installing or updating the latest version of the AWS CLI](#) and [Installing the AWS Tools for PowerShell](#).

### Linux & macOS

```
aws ssm create-document \  
  --content file://path/to/template_in_json_or_yaml \  
  --name "a_name_for_the_template" \  
  --document-type "CloudFormation" \  
  --document-format "JSON_or_YAML" \  
  --tags "Key=tag-key,Value=tag-value"
```

### Windows

```
aws ssm create-document ^
```

```
--content file://C:\path\to\template_in_json_or_yaml ^
--name "a_name_for_the_template" ^
--document-type "CloudFormation" ^
--document-format "JSON_or_YAML" ^
--tags "Key=tag-key,Value=tag-value"
```

## PowerShell

```
$json = Get-Content -Path "C:\path\to\template_in_json_or_yaml" | Out-String
New-SSMDocument `
  -Content $json `
  -Name "a_name_for_the_template" `
  -DocumentType "CloudFormation" `
  -DocumentFormat "JSON_or_YAML" `
  -Tags "Key=tag-key,Value=tag-value"
```

If successful, the command returns a response similar to the following.

```
{
  "DocumentDescription": {
    "Hash": "c1d9640f15fbdba6deb41af6471d6ace0acc22f213bdd1449f03980358c2d4fb",
    "HashType": "Sha256",
    "Name": "MyTestCFTemplate",
    "Owner": "428427166869",
    "CreateDate": "2021-06-04T09:44:18.931000-07:00",
    "Status": "Creating",
    "DocumentVersion": "1",
    "Description": "My test template",
    "PlatformTypes": [],
    "DocumentType": "CloudFormation",
    "SchemaVersion": "1.0",
    "LatestVersion": "1",
    "DefaultVersion": "1",
    "DocumentFormat": "YAML",
    "Tags": [
      {
        "Key": "Templates",
        "Value": "Test"
      }
    ]
  }
}
```

## Editing a template

Use the following procedure to edit a CloudFormation template in Application Manager. Template changes are available in CloudFormation after you provision a stack that uses the updated template.

### To edit a CloudFormation template in Application Manager

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Application Manager**.
3. In the **Applications** section, choose **CloudFormation stacks**.
4. Choose **Template library**.
5. Choose a template, and then choose **Actions, Edit**. You can't change the name of a template, but you can change all other details.
6. Choose **Save**. The template is saved in the Systems Manager Document service.

### Using Application Manager to manage AWS CloudFormation stacks

Application Manager, a capability of AWS Systems Manager, helps you provision and manage resources for your applications by integrating with AWS CloudFormation. You can create, edit, and delete CloudFormation templates and stacks in Application Manager. A *stack* is a collection of AWS resources that you can manage as a single unit. This means you can create, update, or delete a collection of AWS resources by using CloudFormation stacks. A *template* is a formatted text file in JSON or YAML that specifies the resources you want to provision in your stacks. This section includes the following information.

#### Topics

- [Creating a stack](#)
- [Updating a stack](#)

### Creating a stack

The following procedures describe how to create a CloudFormation stack by using Application Manager. A stack is based on a template. When you create a stack, you can either choose an existing template or create a new one. After you create the stack, the system immediately

attempts to create the resources identified in the stack. After the system successfully provisions the resources, the template and the stack are available to view and edit in Application Manager and CloudFormation.

### **Note**

There is no charge to use Application Manager to create a stack, but you are charged for AWS resources created in the stack.

## Creating a CloudFormation stack by using Application Manager (console)

Use the following procedure to create a stack by using Application Manager in the AWS Management Console.

### To create a CloudFormation stack

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Application Manager**.
3. In the **Applications** section, choose **CloudFormation stacks**.
4. In the **Prepare a template** section, choose an option. If you choose **Use an existing template**, you can use the tabs in the **Choose a template** section to locate the template you want. If you choose one of the other options, complete the wizard to prepare a template.
5. On the **Specify template details** page, verify the details of the template to ensure the process creates the resources you want.
  - (Optional) In the **Tags** section, apply one or more tag key name/value pairs to the template.
  - Tags are optional metadata that you assign to a resource. By using tags, you can categorize a resource in different ways, such as by purpose, owner, or environment.
  - Choose **Next**.
6. On the **Edit stack details** page, for **Stack name**, enter a name that helps you identify the resources created by the stack or its purpose.
  - The **Parameters** section includes all optional and required parameters specified in the template. Enter one or more parameters in each field.
  - (Optional) In the **Tags** section, apply one or more tag key name/value pairs to the stack.

- (Optional) In the **Permissions** section, specify an AWS Identity and Access Management (IAM) role name or an IAM Amazon Resource Name (ARN). The system uses the specified service role to create all resources specified in your stack. If you don't specify an IAM role, then AWS CloudFormation uses a temporary session that the system generates from your user credentials. For more information about this IAM role, see [AWS CloudFormation service role](#) in the *AWS CloudFormation User Guide*.
  - Choose **Next**.
7. On the **Review and provision** page, review all the details of the stack. Choose an **Edit** button on this page to make change.
  8. Choose **Provision stack**.

Application Manager displays the **CloudFormation stacks** page and the status of the stack creation and deployment. If CloudFormation fails to create and provision the stack, see the following topics in the *AWS CloudFormation User Guide*.

- [Stack status codes](#)
- [Troubleshooting AWS CloudFormation](#)

After your stack resources are provisioned and running, users can edit resources directly by using the underlying service that created the resource. For example, a user can use the Amazon Elastic Compute Cloud (Amazon EC2) console to update a server instance that was created as part of a CloudFormation stack. Some changes may be accidental, and some may be made intentionally to respond to time-sensitive operational events. Regardless, changes made outside of CloudFormation can complicate stack update or deletion operations. You can use drift detection or *drift status* to identify stack resources to which configuration changes have been made outside of CloudFormation management. For information about drift status, see [Detecting unmanaged configuration changes to stacks and resources](#).

### Creating a CloudFormation stack by using Application Manager (command line)

Use the following AWS Command Line Interface (AWS CLI) procedure to provision a stack by using a CloudFormation template that is stored as an SSM document in Systems Manager. Replace each *example resource placeholder* with your own information. For information about other AWS CLI procedures for creating stacks, see [Creating a stack](#) in the *AWS CloudFormation User Guide*.

### Before you begin

2. In the navigation pane, choose **Application Manager**.
3. In the **Applications** section, choose **CloudFormation stacks**.
4. Choose a stack in the list and then choose **Actions, Update stack**.
5. On the **Specify template source** page, choose one of the following options, and then choose **Next**.
  - Choose **Use the template code currently provisioned in the stack** to view a template. Choose a template version in the **Versions** list, and then choose **Next**.
  - Choose **Switch to a different template** to choose or create a new template for the stack.
6. After you finish making changes to the template, choose **Next**.
7. On the **Edit stack details** page, you can edit parameters, tags, and permissions. You can't change the stack name. Make your changes and choose **Next**.
8. On the **Review and provision** page, review all the details of the stack, and then choose **Provision stack**.

## Working with clusters in Application Manager

This section includes topics to help you work with Amazon Elastic Container Service (Amazon ECS) and Amazon Elastic Kubernetes Service (Amazon EKS) container clusters in Application Manager, a component of AWS Systems Manager.

### Contents

- [Working with Amazon ECS in Application Manager](#)
- [Working with Amazon EKS in Application Manager](#)
- [Working with runbooks for clusters](#)

## Working with Amazon ECS in Application Manager

With Application Manager, a capability of AWS Systems Manager, you can view and manage your Amazon Elastic Container Service (Amazon ECS) cluster infrastructure. Application Manager applies a tag to your Amazon ECS cluster using the Amazon Resource Name (ARN) of the cluster as the tag value. Application Manager provides a component runtime view of the compute, networking, and storage resources in a cluster.

**Note**

You can't manage or view operations information about your containers in Application Manager. You can only manage and view operations information about the infrastructure hosting your Amazon ECS resources.

**Actions you can perform on this page**

You can perform the following actions on this page:

- Choose **Manage cluster** to open the cluster in Amazon ECS.
- Choose **View all** to view a list of resources in your cluster.
- Choose **View in CloudWatch** to view resource alarms in Amazon CloudWatch.
- Choose **Manage nodes** or **Manage Fargate profiles** to view these resources in Amazon ECS.
- Choose a resource ID to view detailed information about it in the console where it was created.
- View a list of OpsItems related to your clusters.
- View a history of runbooks that have been run on your clusters.

**To open an ECS cluster**

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Application Manager**.
3. In the **Container clusters** section, choose **ECS clusters**.
4. Choose a cluster in the list. Application Manager opens the **Overview** tab.

**Working with Amazon EKS in Application Manager**

Application Manager, a capability of AWS Systems Manager, integrates with [Amazon Elastic Kubernetes Service](#) (Amazon EKS) to provide information about the health of your Amazon EKS cluster infrastructure. Application Manager applies a tag to your Amazon EKS cluster using the Amazon Resource Name (ARN) of the cluster as the tag value. Application Manager provides a component runtime view of the compute, networking, and storage resources in a cluster.

**Note**

You can't manage or view operations information about your Amazon EKS pods or containers in Application Manager. You can only manage and view operations information about the infrastructure hosting your Amazon EKS resources.

**Actions you can perform on this page**

You can perform the following actions on this page:

- Choose **Manage cluster** to open the cluster in Amazon EKS.
- Choose **View all** to view a list of resources in your cluster.
- Choose **View in CloudWatch** to view resource alarms in Amazon CloudWatch.
- Choose **Manage nodes** or **Manage Fargate profiles** to view these resources in Amazon EKS.
- Choose a resource ID to view detailed information about it in the console where it was created.
- View a list of OpsItems related to your clusters.
- View a history of runbooks that have been run on your clusters.

**To open an EKS clusters application**

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Application Manager**.
3. In the **Container clusters** section, choose **EKS clusters**.
4. Choose a cluster in the list. Application Manager opens the **Overview** tab.

**Working with runbooks for clusters**

You can remediate issues with AWS resources from Application Manager, a capability of AWS Systems Manager, by using Systems Manager Automation runbooks. When you choose **Start runbook** from an Application Manager cluster, the system displays a filtered list of runbooks based on the type of resources in your cluster. When you choose the runbook you want to start, Systems Manager opens the **Execute automation document** page.

**Before you begin**

Before you start a runbook from Application Manager, do the following:

- Verify that you have the correct permissions for starting runbooks. For more information, see [Setting up Automation](#).
- Review the Automation procedure documentation about starting runbooks. For more information, see [Run an automated operation powered by Systems Manager Automation](#).
- If you intend to start runbooks on multiple resources at one time, review the documentation about using targets and rate controls. For more information, see [Run automated operations at scale](#).

### To start a runbook for clusters from Application Manager

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Application Manager**.
3. In the **Container clusters** section, choose a container type.
4. Choose the cluster in the list. Application Manager opens the **Overview** tab.
5. On the **Runbooks** tab, choose **Start runbook**. Application Manager opens the **Execute automation document** page in a new tab. For information about the options in the **Execute automation document** page, see [Run an automated operation powered by Systems Manager Automation](#).

## AWS AppConfig

AWS AppConfig feature flags and dynamic configurations help software builders quickly and securely adjust application behavior in production environments without full code deployments. AWS AppConfig speeds up software release frequency, improves application resiliency, and helps you address emergent issues more quickly. With feature flags, you can gradually release new capabilities to users and measure the impact of those changes before fully deploying the new capabilities to all users. With operational flags and dynamic configurations, you can update block lists, allow lists, throttling limits, logging verbosity, and perform other operational tuning to quickly respond to issues in production environments.

For more information, see [What Is AWS AppConfig?](#) in the *AWS AppConfig User Guide*.

## AWS Systems Manager Parameter Store

Parameter Store, a capability of AWS Systems Manager, provides secure, hierarchical storage for configuration data management and secrets management. You can store data such as passwords, database strings, Amazon Machine Image (AMI) IDs, and license codes as parameter values. You can store values as plain text or encrypted data. You can reference Systems Manager parameters in your scripts, commands, SSM documents, and configuration and automation workflows by using the unique name that you specified when you created the parameter. To get started with Parameter Store, open the [Systems Manager console](#). In the navigation pane, choose **Parameter Store**.

Parameter Store is also integrated with Secrets Manager. You can retrieve Secrets Manager secrets when using other AWS services that already support references to Parameter Store parameters. For more information, see [Referencing AWS Secrets Manager secrets from Parameter Store parameters](#).

### Note

To implement password rotation lifecycles, use AWS Secrets Manager. You can rotate, manage, and retrieve database credentials, API keys, and other secrets throughout their lifecycle using Secrets Manager. For more information, see [What is AWS Secrets Manager?](#) in the *AWS Secrets Manager User Guide*.

## How can Parameter Store benefit my organization?

Parameter Store offers these benefits:

- Use a secure, scalable, hosted secrets management service with no servers to manage.
- Improve your security posture by separating your data from your code.
- Store configuration data and encrypted strings in hierarchies and track versions.
- Control and audit access at granular levels.
- Store parameters reliably because Parameter Store is hosted in multiple Availability Zones in an AWS Region.

## Who should use Parameter Store?

- Any AWS customer who wants to have a centralized way to manage configuration data.

- Software developers who want to store different logins and reference streams.
- Administrators who want to receive notifications when their secrets and passwords are or aren't changed.

## What are the features of Parameter Store?

- **Change notification**

You can configure change notifications and invoke automated actions for both parameters and parameter policies. For more information, see [Setting up notifications or triggering actions based on Parameter Store events](#).

- **Organize parameters**

You can tag your parameters individually to help you identify one or more parameters based on the tags you've assigned to them. For example, you can tag parameters for specific environments or departments.

- **Label versions**

You can associate an alias for versions of your parameter by creating labels. Labels can help you remember the purpose of a parameter version when there are multiple versions.

- **Data validation**

You can create parameters that point to an Amazon Elastic Compute Cloud (Amazon EC2) instance and Parameter Store validates these parameters to make sure that it references expected resource type, that the resource exists, and that the customer has permission to use the resource. For example, you can create a parameter with Amazon Machine Image (AMI) ID as a value with `aws:ec2:image` data type, and Parameter Store performs an asynchronous validation operation to make sure that the parameter value meets the formatting requirements for an AMI ID, and that the specified AMI is available in your AWS account.

- **Reference secrets**

Parameter Store is integrated with AWS Secrets Manager so that you can retrieve Secrets Manager secrets when using other AWS services that already support references to Parameter Store parameters.

- **Share parameters with other accounts**

You can optionally centralize configuration data in a single AWS account and share parameters with other accounts that need to access them.

- **Accessible from other AWS services**

You can use Parameter Store parameters with other Systems Manager capabilities and AWS services to retrieve secrets and configuration data from a central store. Parameters work with Systems Manager capabilities such as Run Command, Automation, and State Manager, capabilities of AWS Systems Manager. You can also reference parameters in a number of other AWS services, including the following:

- Amazon Elastic Compute Cloud (Amazon EC2)
- Amazon Elastic Container Service (Amazon ECS)
- AWS Secrets Manager
- AWS Lambda
- AWS CloudFormation
- AWS CodeBuild
- AWS CodePipeline
- AWS CodeDeploy

- **Integrate with other AWS services**

Configure integration with the following AWS services for encryption, notification, monitoring, and auditing:

- AWS Key Management Service (AWS KMS)
- Amazon Simple Notification Service (Amazon SNS)
- Amazon CloudWatch: For more information, see [Configuring EventBridge rules for parameters and parameter policies](#).
- Amazon EventBridge: For more information, see [Monitoring Systems Manager status changes using Amazon SNS notifications](#) and [Reference: Amazon EventBridge event patterns and types for Systems Manager](#).
- AWS CloudTrail: For more information, see [Logging AWS Systems Manager API calls with AWS CloudTrail](#).

## What is a parameter?

A Parameter Store parameter is any piece of data that is saved in Parameter Store, such as a block of text, a list of names, a password, an AMI ID, a license key, and so on. You can centrally and securely reference this data in your scripts, commands, and SSM documents.

When you reference a parameter, you specify the parameter name by using the following convention.

```
{{ssm:parameter-name}}
```

### Note

Parameters can't be referenced or nested in the values of other parameters. You can't include `{{}}` or `{{ssm:parameter-name}}` in a parameter value.

Parameter Store provides support for three types of parameters: `String`, `StringList`, and `SecureString`.

With one exception, when you create or update a parameter, you enter the parameter value as plaintext, and Parameter Store performs no validation on the text you enter. For `String` parameters, however, you can specify the data type as `aws:ec2:image`, and Parameter Store validates that the value you enter is the proper format for an Amazon EC2 AMI; for example: `ami-12345abcdeEXAMPLE`.

### Parameter type: `String`

By default, `String` parameters consist of any block of text you enter. For example:

- abc123
- Example Corp
- ``

### Parameter type: `StringList`

`StringList` parameters contain a comma-separated list of values, as shown in the following examples.

Monday,Wednesday,Friday

CSV, TSV, CLF, ELF, JSON

## Parameter type: SecureString

A `SecureString` parameter is any sensitive data that needs to be stored and referenced in a secure manner. If you have data that you don't want users to alter or reference in plaintext, such as passwords or license keys, create those parameters using the `SecureString` data type.

### Important

Don't store sensitive data in a `String` or `StringList` parameter. For all sensitive data that must remain encrypted, use only the `SecureString` parameter type.

For more information, see [Creating a SecureString parameter using the AWS CLI](#).

We recommend using `SecureString` parameters for the following scenarios:

- You want to use data/parameters across AWS services without exposing the values as plaintext in commands, functions, agent logs, or CloudTrail logs.
- You want to control who has access to sensitive data.
- You want to be able to audit when sensitive data is accessed (CloudTrail).
- You want to encrypt your sensitive data, and you want to bring your own encryption keys to manage access.

### Important

Only the *value* of a `SecureString` parameter is encrypted. Parameter names, descriptions, and other properties aren't encrypted.

You can use the `SecureString` parameter type for textual data that you want to encrypt, such as passwords, application secrets, confidential configuration data, or any other types of data that you want to protect. `SecureString` data is encrypted and decrypted using an AWS KMS key. You can use either a default KMS key provided by AWS or create and use your own AWS KMS key. (Use your own AWS KMS key if you want to restrict user access to `SecureString` parameters. For more information, see [IAM permissions for using AWS default keys and customer managed keys](#).)

You can also use SecureString parameters with other AWS services. In the following example, the Lambda function retrieves a SecureString parameter by using the [GetParameters](#) API.

```
import json
import boto3
ssm = boto3.client('ssm', 'us-east-2')
def get_parameters():
    response = ssm.get_parameters(
        Names=['LambdaSecureString'],WithDecryption=True
    )
    for parameter in response['Parameters']:
        return parameter['Value']

def lambda_handler(event, context):
    value = get_parameters()
    print("value1 = " + value)
    return value # Echo back the first key value
```

## AWS KMS encryption and pricing

If you choose the SecureString parameter type when you create your parameter, Systems Manager uses AWS KMS to encrypt the parameter value.

### Important

Parameter Store only supports [symmetric encryption KMS keys](#). You can't use an [asymmetric encryption KMS key](#) to encrypt your parameters. For help determining whether a KMS key is symmetric or asymmetric, see [Identifying symmetric and asymmetric KMS keys](#) in the *AWS Key Management Service Developer Guide*

There is no charge from Parameter Store to create a SecureString parameter, but charges for use of AWS KMS encryption do apply. For information, see [AWS Key Management Service pricing](#).

For more information about AWS managed keys and customer managed keys, see [AWS Key Management Service Concepts](#) in the *AWS Key Management Service Developer Guide*. For more information about Parameter Store and AWS KMS encryption, see [How AWS Systems Manager Parameter Store Uses AWS KMS](#).

**Note**

To view an AWS managed key, use the AWS KMS DescribeKey operation. This AWS Command Line Interface (AWS CLI) example uses DescribeKey to view an AWS managed key.

```
aws kms describe-key --key-id alias/aws/ssm
```

**More info**

- [Creating a SecureString parameter in Parameter Store and joining a node to a Domain \(PowerShell\)](#)
- [Use Parameter Store to Securely Access Secrets and Config Data in CodeDeploy](#)
- [Interesting Articles on Amazon EC2 Systems Manager Parameter Store](#)

**Setting up Parameter Store**

Before setting up parameters in Parameter Store, a capability of AWS Systems Manager, first configure AWS Identity and Access Management (IAM) policies that provide users in your account with permission to perform the actions you specify.

This section includes information about how to manually configure these policies using the IAM console, and how to assign them to users and user groups. You can also create and assign policies to control which parameter actions can be run on a managed node.

This section also includes information about how to create Amazon EventBridge rules that let you receive notifications about changes to Systems Manager parameters. You can also use EventBridge rules to invoke other actions in AWS based on changes in Parameter Store.

**Contents**

- [Restricting access to Parameter Store parameters using IAM policies](#)
- [Managing parameter tiers](#)
- [Increasing or resetting Parameter Store throughput](#)
- [Setting up notifications or triggering actions based on Parameter Store events](#)

## Restricting access to Parameter Store parameters using IAM policies

You restrict access to AWS Systems Manager parameters by using AWS Identity and Access Management (IAM). More specifically, you create IAM policies that restrict access to the following API operations:

- [DeleteParameter](#)
- [DeleteParameters](#)
- [DescribeParameters](#)
- [GetParameter](#)
- [GetParameters](#)
- [GetParameterHistory](#)
- [GetParametersByPath](#)
- [PutParameter](#)

When using IAM policies to restrict access to Systems Manager parameters, we recommend that you create and use *restrictive* IAM policies. For example, the following policy allows a user to call the `DescribeParameters` and `GetParameters` API operations for a limited set of resources. This means that the user can get information about and use all parameters that begin with `prod-*`.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ssm:DescribeParameters"
      ],
      "Resource": "*"
    },
    {
      "Effect": "Allow",
      "Action": [
        "ssm:GetParameters"
      ],
      "Resource": "arn:aws:ssm:us-east-2:123456789012:parameter/prod-*"
    }
  ]
}
```

}

**⚠ Important**

If a user has access to a path, then the user can access all levels of that path. For example, if a user has permission to access path `/a`, then the user can also access `/a/b`. Even if a user has explicitly been denied access in IAM for parameter `/a/b`, they can still call the `GetParametersByPath` API operation recursively for `/a` and view `/a/b`.

For trusted administrators, you can provide access to all Systems Manager parameter API operations by using a policy similar to the following example. This policy gives the user full access to all production parameters that begin with `dbserver-prod-*`.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ssm:PutParameter",
        "ssm>DeleteParameter",
        "ssm:GetParameterHistory",
        "ssm:GetParametersByPath",
        "ssm:GetParameters",
        "ssm:GetParameter",
        "ssm>DeleteParameters"
      ],
      "Resource": "arn:aws:ssm:us-east-2:123456789012:parameter/dbserver-prod-*"
    },
    {
      "Effect": "Allow",
      "Action": "ssm:DescribeParameters",
      "Resource": "*"
    }
  ]
}
```

## Denying permissions

Each API is unique and has distinct operations and permissions that you can allow or deny individually. An explicit deny in any policy overrides the allow.

### Note

The default AWS Key Management Service (AWS KMS) key has Decrypt permission for all IAM principals within the AWS account. If you want to have different access levels to SecureString parameters in your account, we don't recommend that you use the default key.

If you want all API operations retrieving parameter values to have the same behavior, then you can use a pattern like `GetParameter*` in a policy. The following example shows how to deny `GetParameter`, `GetParameters`, `GetParameterHistory`, and `GetParametersByPath` for all parameters beginning with `prod-*`.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Deny",
      "Action": [
        "ssm:GetParameter*"
      ],
      "Resource": "arn:aws:ssm:us-east-2:123456789012:parameter/prod-*"
    }
  ]
}
```

The following example shows how to deny some commands while allowing the user to perform other commands on all parameters that begin with `prod-*`.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Deny",
      "Action": [
```

```

        "ssm:PutParameter",
        "ssm>DeleteParameter",
        "ssm>DeleteParameters",
        "ssm:DescribeParameters"
    ],
    "Resource": "*"
},
{
    "Effect": "Allow",
    "Action": [
        "ssm:GetParametersByPath",
        "ssm:GetParameters",
        "ssm:GetParameter",
        "ssm:GetParameterHistory"
    ],
    "Resource": "arn:aws:ssm:us-east-2:123456789012:parameter/prod-*"
}
]
}

```

### Note

The parameter history includes all parameter versions, including the current one. Therefore, if a user is denied permission for `GetParameter`, `GetParameters`, and `GetParameterByPath` but is allowed permission for `GetParameterHistory`, they can see the current parameter, including `SecureString` parameters, using `GetParameterHistory`.

## Allowing only specific parameters to run on nodes

You can control access so that managed nodes can run only parameters that you specify.

If you choose the `SecureString` parameter type when you create your parameter, Systems Manager uses AWS KMS to encrypt the parameter value. AWS KMS encrypts the value by using either an AWS managed key or a customer managed key. For more information about AWS KMS and AWS KMS key, see the [AWS Key Management Service Developer Guide](#).

You can view the AWS managed key by running the following command from the AWS CLI.

```
aws kms describe-key --key-id alias/aws/ssm
```

The following example allows nodes to get a parameter value only for parameters that begin with `prod-`. If the parameter is a `SecureString` parameter, then the node decrypts the string using AWS KMS.

### Note

Instance policies, like in the following example, are assigned to the instance role in IAM. For more information about configuring access to Systems Manager features, including how to assign policies to users and instances, see [Managing EC2 instances with Systems Manager](#).

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ssm:GetParameters"
      ],
      "Resource": [
        "arn:aws:ssm:us-east-2:123456789012:parameter/prod-*"
      ]
    },
    {
      "Effect": "Allow",
      "Action": [
        "kms:Decrypt"
      ],
      "Resource": [
        "arn:aws:kms:us-east-2:123456789012:key/4914ec06-e888-4ea5-
a371-5b88eEXAMPLE"
      ]
    }
  ]
}
```

## IAM permissions for using AWS default keys and customer managed keys

Parameter Store `SecureString` parameters are encrypted and decrypted using AWS KMS keys. You can choose to encrypt your `SecureString` parameters using either an AWS KMS key or the default KMS key provided by AWS.

When using a customer managed key, the IAM policy that grants a user access to a parameter or parameter path must provide explicit `kms:Encrypt` permissions for the key. For example, the following policy allows a user to create, update, and view `SecureString` parameters that begin with `prod-` in the specified AWS Region and AWS account.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ssm:PutParameter",
        "ssm:GetParameter",
        "ssm:GetParameters"
      ],
      "Resource": [
        "arn:aws:ssm:us-east-2:111122223333:parameter/prod-*"
      ]
    },
    {
      "Effect": "Allow",
      "Action": [
        "kms:Decrypt",
        "kms:Encrypt",
        "kms:GenerateDataKey"
      ],
      "Resource": [
        "arn:aws:kms:us-east-2:111122223333:key/1234abcd-12ab-34cd-56ef-12345EXAMPLE"
      ]
    }
  ]
}
```

<sup>1</sup>The `kms:GenerateDataKey` permission is required for creating encrypted advanced parameters using the specified customer managed key.

By contrast, all users within the customer account have access to the default AWS managed key. If you use this default key to encrypt `SecureString` parameters and don't want users to work with

SecureString parameters, their IAM policies must explicitly deny access to the default key, as demonstrated in the following policy example.

 **Note**

You can locate the Amazon Resource Name (ARN) of the default key in the AWS KMS console on the [AWS managed keys](#) page. The default key is the one identified with `aws/ssm` in the **Alias** column.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Deny",
      "Action": [
        "kms:Decrypt",
        "kms:GenerateDataKey"
      ],
      "Resource": [
        "arn:aws:kms:us-east-2:111122223333:key/abcd1234-ab12-cd34-ef56-
abcdeEXAMPLE"
      ]
    }
  ]
}
```

If you require fine-grained access control over the SecureString parameters in your account, you should use a customer managed key to protect and restrict access to these parameters. We also recommend using AWS CloudTrail to monitor SecureString parameter activities.

For more information, see the following topics:

- [Policy evaluation logic](#) in the *IAM User Guide*
- [Using key policies in AWS KMS](#) in the *AWS Key Management Service Developer Guide*
- [Viewing events with CloudTrail Event history](#) in the *AWS CloudTrail User Guide*

## Managing parameter tiers

Parameter Store, a capability of AWS Systems Manager, includes *standard parameters* and *advanced parameters*. You individually configure parameters to use either the standard-parameter tier (the default tier) or the advanced-parameter tier.

You can change a standard parameter to an advanced parameter at any time, but you can't revert an advanced parameter to a standard parameter. This is because reverting an advanced parameter to a standard parameter would cause the system to truncate the size of the parameter from 8 KB to 4 KB, resulting in data loss. Reverting would also remove any policies attached to the parameter. Also, advanced parameters use a different form of encryption than standard parameters. For more information, see [How AWS Systems Manager Parameter Store uses AWS KMS](#) in the *AWS Key Management Service Developer Guide*.

If you no longer need an advanced parameter, or if you no longer want to incur charges for an advanced parameter, delete it and recreate it as a new standard parameter.

The following table describes the differences between the tiers.

|  | Standard             | Advanced   |
|--|----------------------|--|
| Total number of parameters allowed<br><br>(per AWS account and AWS Region) | 10,000               | 100,000  |
| Maximum size of a parameter value  | 4 KB                 | 8 KB   |
| Parameter policies available   | No                   | Yes<br><br>For more information, see <a href="#">Assigning parameter policies in Parameter Store</a> . |
| Cost   | No additional charge | Charges apply  |

|  | Standard | Advanced  |
|--|----------|---|
|  |          | For more information, see <a href="#">AWS Systems Manager Pricing for Parameter Store</a> . |

## Topics

- [Specifying a default parameter tier](#)
- [Changing a standard parameter to an advanced parameter](#)

## Specifying a default parameter tier

In requests to create or update a parameter (that is, the [PutParameter](#) operation), you can specify the parameter tier to use in the request. The following is an example, using the AWS Command Line Interface (AWS CLI).

### Linux & macOS

```
aws ssm put-parameter \  
  --name "default-ami" \  
  --type "String" \  
  --value "t2.micro" \  
  --tier "Standard"
```

### Windows

```
aws ssm put-parameter ^  
  --name "default-ami" ^  
  --type "String" ^  
  --value "t2.micro" ^  
  --tier "Standard"
```

Whenever you specify a tier in the request, Parameter Store creates or updates the parameter according to your request. However, if you don't explicitly specify a tier in a request, the Parameter Store default tier setting determines which tier the parameter is created in.

The default tier when you begin using Parameter Store is the standard-parameter tier. If you use the advanced-parameter tier, you can specify one of the following as the default:

- **Advanced:** With this option, Parameter Store evaluates all requests as advanced parameters.
- **Intelligent-Tiering:** With this option, Parameter Store evaluates each request to determine if the parameter is standard or advanced.

If the request doesn't include any options that require an advanced parameter, the parameter is created in the standard-parameter tier. If one or more options requiring an advanced parameter are included in the request, Parameter Store creates a parameter in the advanced-parameter tier.

## Benefits of Intelligent-Tiering

The following are reasons you might choose Intelligent-Tiering as the default tier.

**Cost control** – Intelligent-Tiering helps control your parameter-related costs by always creating standard parameters unless an advanced parameter is absolutely necessary.

**Automatic upgrade to the advanced-parameter tier** – When you make a change to your code that requires upgrading a standard parameter to an advanced parameter, Intelligent-Tiering handles the conversion for you. You don't need to change your code to handle the upgrade.

Here are some examples of automatic upgrades:

- Your AWS CloudFormation templates provision numerous parameters when they're run. When this process causes you to reach the 10,000 parameter quota in the standard-parameter tier, Intelligent-Tiering automatically upgrades you to the advanced-parameter tier, and your AWS CloudFormation processes aren't interrupted.
- You store a certificate value in a parameter, rotate the certificate value regularly, and the content is less than the 4 KB quota of the standard-parameter tier. If a replacement certificate value exceeds 4 KB, Intelligent-Tiering automatically upgrades the parameter to the advanced-parameter tier.
- You want to associate numerous existing standard parameters to a parameter policy, which requires the advanced-parameter tier. Instead of your having to include the option `--tier Advanced` in all the calls to update the parameters, Intelligent-Tiering automatically upgrades the parameters to the advanced-parameter tier. The Intelligent-Tiering option upgrades parameters from standard to advanced whenever criteria for the advanced-parameter tier are introduced.

Options that require an advanced parameter include the following:

- The content size of the parameter is more than 4 KB.
- The parameter uses a parameter policy.
- More than 10,000 parameters already exist in your AWS account in the current AWS Region.

## Default Tier Options

The tier options you can specify as the default include the following.

- **Standard** – The standard-parameter tier is the default tier when you begin to use Parameter Store. Using the standard-parameter tier, you can create 10,000 parameters for each AWS Region in an AWS account. The content size of each parameter can equal a maximum of 4 KB. Standard parameters don't support parameter policies. There is no additional charge to use the standard-parameter tier. Choosing **Standard** as the default tier means that Parameter Store always attempts to create a standard parameter for requests that don't specify a tier.
- **Advanced** – Use the advanced-parameter tier to create a maximum of 100,000 parameters for each AWS Region in an AWS account. The content size of each parameter can equal a maximum of 8 KB. Advanced parameters support parameter policies. To share a parameter, it must be in the advanced parameter tier. There is a charge to use the advanced-parameter tier. For more information, see [AWS Systems Manager Pricing for Parameter Store](#). Choosing **Advanced** as the default tier means that Parameter Store always attempts to create an advanced parameter for requests that don't specify a tier.

### Note

When you choose the advanced-parameter tier, explicitly authorize AWS to charge your account for any advanced parameters you create.

- **Intelligent-Tiering** – With the Intelligent-Tiering option, Parameter Store determines whether to use the standard-parameter tier or advanced-parameter tier based on the content of the request. For example, if you run a command to create a parameter with content under 4 KB, and there are fewer than 10,000 parameters in the current AWS Region in your AWS account, and you don't specify a parameter policy, a standard parameter is created. If you run a command to create a parameter with more than 4 KB of content, you already have more than 10,000 parameters in the current AWS Region in your AWS account, or you specify a parameter policy, an advanced parameter is created.

**Note**

When you choose Intelligent-Tiering, explicitly authorize AWS to charge your account for any advanced parameters you created.

You can change the Parameter Store default tier setting at any time.

**Configuring permissions to specify a Parameter Store default tier**

Verify that you have permission in AWS Identity and Access Management (IAM) to change the default parameter tier in Parameter Store by doing one of the following:

- Make sure that you attach the `AdministratorAccess` policy to your IAM entity (such as user, group, or role).
- Make sure that you have permission to change the default tier setting by using the following API operations:
  - [GetServiceSetting](#)
  - [UpdateServiceSetting](#)
  - [ResetServiceSetting](#)

Grant the following permissions to the IAM entity to allow a user to view and change the default tier setting for parameters in a specific AWS Region in an AWS account.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ssm:GetServiceSetting"
      ],
      "Resource": "*"
    },
    {
      "Effect": "Allow",
      "Action": [
        "ssm:UpdateServiceSetting"
      ]
    }
  ]
}
```

```

    ],
    "Resource": "arn:aws:ssm:region:account-id:servicesetting/ssm/parameter-
store/default-parameter-tier"
  }
]
}

```

Administrators can specify read-only permission by assigning the following permissions.

```

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ssm:GetServiceSetting"
      ],
      "Resource": "*"
    },
    {
      "Effect": "Deny",
      "Action": [
        "ssm:ResetServiceSetting",
        "ssm:UpdateServiceSetting"
      ],
      "Resource": "*"
    }
  ]
}

```

To provide access, add permissions to your users, groups, or roles:

- Users and groups in AWS IAM Identity Center:

Create a permission set. Follow the instructions in [Create a permission set](#) in the *AWS IAM Identity Center User Guide*.

- Users managed in IAM through an identity provider:

Create a role for identity federation. Follow the instructions in [Create a role for a third-party identity provider \(federation\)](#) in the *IAM User Guide*.

- IAM users:

- Create a role that your user can assume. Follow the instructions in [Create a role for an IAM user](#) in the *IAM User Guide*.
- (Not recommended) Attach a policy directly to a user or add a user to a user group. Follow the instructions in [Adding permissions to a user \(console\)](#) in the *IAM User Guide*.

## Specifying or changing the Parameter Store default tier using the console

The following procedure shows how to use the Systems Manager console to specify or change the default parameter tier for the current AWS account and AWS Region.

### Tip

If you haven't created a parameter yet, you can use the AWS Command Line Interface (AWS CLI) or AWS Tools for Windows PowerShell to change the default parameter tier. For information, see [Specifying or changing the Parameter Store default tier using the AWS CLI](#) and [Specifying or changing the Parameter Store default tier \(PowerShell\)](#).

## To specify or change the Parameter Store default tier

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Parameter Store**.
3. Choose the **Settings** tab.
4. Choose **Change default tier**.
5. Choose one of the following options.
  - **Standard**
  - **Advanced**
  - **Intelligent-Tiering**

For information about these options, see [Specifying a default parameter tier](#).

6. Review the message, and choose **Confirm**.

If you want to change the default tier setting later, repeat this procedure and specify a different default tier option.

## Specifying or changing the Parameter Store default tier using the AWS CLI

The following procedure shows how to use the AWS CLI to change the default parameter tier setting for the current AWS account and AWS Region.

### To specify or change the Parameter Store default tier using the AWS CLI

1. Open the AWS CLI and run the following command to change the default parameter tier setting for a specific AWS Region in an AWS account.

```
aws ssm update-service-setting --setting-id arn:aws:ssm:region:account-id:servicesetting/ssm/parameter-store/default-parameter-tier --setting-value tier-option
```

*region* represents the identifier for an AWS Region supported by AWS Systems Manager, such as `us-east-2` for the US East (Ohio) Region. For a list of supported *region* values, see the **Region** column in [Systems Manager service endpoints](#) in the *Amazon Web Services General Reference*.

*tier-option* values include Standard, Advanced, and Intelligent-Tiering. For information about these options, see [Specifying a default parameter tier](#).

There is no output if the command succeeds.

2. Run the following command to view the current default parameter tier service settings for Parameter Store in the current AWS account and AWS Region.

```
aws ssm get-service-setting --setting-id arn:aws:ssm:region:account-id:servicesetting/ssm/parameter-store/default-parameter-tier
```

The system returns information similar to the following.

```
{
  "ServiceSetting": {
    "SettingId": "/ssm/parameter-store/default-parameter-tier",
    "SettingValue": "Advanced",
    "LastModifiedDate": 1556551683.923,
```

```
    "LastModifiedUser": "arn:aws:sts::123456789012:assumed-role/Administrator/Jasper",
    "ARN": "arn:aws:ssm:us-east-2:123456789012:servicesetting/ssm/parameter-store/default-parameter-tier",
    "Status": "Customized"
  }
}
```

If you want to change the default tier setting again, repeat this procedure and specify a different `SettingValue` option.

### Specifying or changing the Parameter Store default tier (PowerShell)

The following procedure shows how to use the Tools for Windows PowerShell to change the default parameter tier setting for a specific AWS Region in an Amazon Web Services account.

#### To specify or change the Parameter Store default tier using PowerShell

1. Change the Parameter Store default tier in the current AWS account and AWS Region using the AWS Tools for PowerShell (Tools for PowerShell).

```
Update-SSMServiceSetting -SettingId "arn:aws:ssm:region:account-id:servicesetting/ssm/parameter-store/default-parameter-tier" -SettingValue "tier-option" -Region region
```

*region* represents the identifier for an AWS Region supported by AWS Systems Manager, such as `us-east-2` for the US East (Ohio) Region. For a list of supported *region* values, see the **Region** column in [Systems Manager service endpoints](#) in the *Amazon Web Services General Reference*.

*tier-option* values include Standard, Advanced, and Intelligent-Tiering. For information about these options, see [Specifying a default parameter tier](#).

There is no output if the command succeeds.

2. Run the following command to view the current default parameter tier service settings for Parameter Store in the current AWS account and AWS Region.

```
Get-SSMServiceSetting -SettingId "arn:aws:ssm:region:account-id:servicesetting/ssm/parameter-store/default-parameter-tier" -Region region
```

*region* represents the identifier for an AWS Region supported by AWS Systems Manager, such as `us-east-2` for the US East (Ohio) Region. For a list of supported *region* values, see the **Region** column in [Systems Manager service endpoints](#) in the *Amazon Web Services General Reference*.

The system returns information similar to the following.

```
ARN : arn:aws:ssm:us-east-2:123456789012:servicesetting/ssm/parameter-store/default-parameter-tier
LastModifiedDate : 4/29/2019 3:35:44 PM
LastModifiedUser : arn:aws:sts::123456789012:assumed-role/Administrator/Jasper
SettingId       : /ssm/parameter-store/default-parameter-tier
SettingValue    : Advanced
Status         : Customized
```

If you want to change the default tier setting again, repeat this procedure and specify a different `SettingValue` option.

### Changing a standard parameter to an advanced parameter

Use the following procedure to change an existing standard parameter to an advanced parameter. For information about how to create a new advanced parameter, see [Creating Parameter Store parameters in Systems Manager](#).

#### To change a standard parameter to an advanced parameter

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Parameter Store**.
3. Choose a parameter, and then choose **Edit**.
4. For **Description**, enter information about this parameter.
5. Choose **Advanced**.
6. For **Value**, enter the value of this parameter. Advanced parameters have a maximum value limit of 8 KB.
7. Choose **Save changes**.

## Increasing or resetting Parameter Store throughput

Increasing Parameter Store throughput increases the maximum number of transactions per second (TPS) that Parameter Store, a capability of AWS Systems Manager, can process. Increased throughput allows you to operate Parameter Store at higher volumes to support applications and workloads that need concurrent access to multiple parameters. You can increase the quota up to the max throughput on the **Settings** tab.

For more information about max throughput default and maximum limits, see [AWS Systems Manager endpoints and quotas](#).

Increasing the throughput quota incurs a charge on your AWS account. For more information, see [AWS Systems Manager Pricing](#).

### Note

The Parameter Store throughput setting applies to all transactions created by all IAM users in the current AWS account and AWS Region. The throughput setting applies to standard and advanced parameters.

## Topics

- [Configuring permissions to change Parameter Store throughput](#)
- [Increasing or resetting throughput using the console](#)
- [Increasing or resetting throughput using the AWS CLI](#)
- [Increasing or resetting throughput \(PowerShell\)](#)

## Configuring permissions to change Parameter Store throughput

Verify that you have permission in IAM to change Parameter Store throughput by doing one of the following:

- Make sure that the AdministratorAccess policy is attached to your IAM entity (user, group, or role).
- Make sure that you have permission to change the throughput service setting by using the following API operations:
  - [GetServiceSetting](#)
  - [UpdateServiceSetting](#)

- [ResetServiceSetting](#)

Grant the following permissions to the IAM entity to allow a user to view and change the parameter-throughput setting for parameters in a specific AWS Region in an AWS account.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ssm:GetServiceSetting"
      ],
      "Resource": "*"
    },
    {
      "Effect": "Allow",
      "Action": [
        "ssm:UpdateServiceSetting"
      ],
      "Resource": "arn:aws:ssm:region:account-id:servicesetting/ssm/parameter-
store/high-throughput-enabled"
    }
  ]
}
```

Administrators can specify read-only permission by assigning the following permissions.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ssm:GetServiceSetting"
      ],
      "Resource": "*"
    },
    {
      "Effect": "Deny",
      "Action": [
        "ssm:ResetServiceSetting",

```

```
        "ssm:UpdateServiceSetting"
      ],
      "Resource": "*"
    }
  ]
}
```

To provide access, add permissions to your users, groups, or roles:

- Users and groups in AWS IAM Identity Center:

Create a permission set. Follow the instructions in [Create a permission set](#) in the *AWS IAM Identity Center User Guide*.

- Users managed in IAM through an identity provider:

Create a role for identity federation. Follow the instructions in [Create a role for a third-party identity provider \(federation\)](#) in the *IAM User Guide*.

- IAM users:

- Create a role that your user can assume. Follow the instructions in [Create a role for an IAM user](#) in the *IAM User Guide*.
- (Not recommended) Attach a policy directly to a user or add a user to a user group. Follow the instructions in [Adding permissions to a user \(console\)](#) in the *IAM User Guide*.

## Increasing or resetting throughput using the console

The following procedure shows how to use the Systems Manager console to increase the number of transactions per second that Parameter Store can process for the current AWS account and AWS Region. It also shows how to revert to the standard settings if you no longer need increased throughput or no longer want to incur charges.

### Tip

If you haven't created a parameter yet, you can use the AWS Command Line Interface (AWS CLI) or AWS Tools for Windows PowerShell to increase throughput. For information, see [Increasing or resetting throughput using the AWS CLI](#) and [Increasing or resetting throughput \(PowerShell\)](#).

## To increase or reset Parameter Store throughput

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Parameter Store**.
3. Choose the **Settings** tab.
4. To increase throughput, choose **Set limit**.

-or-

To revert to the default limit, choose **Reset limit**.

5. If you are increasing the limit, do the following:
  - Select the check box for **I accept that changing this setting incurs charges on my AWS account**.
  - Choose **Set limit**.

-or-

If you are resetting the limit to the default, do the following:

- Select the check box for **I accept that resetting to the default throughput limit causes Parameter Store to process fewer transactions per second**.
- Choose **Reset limit**.

## Increasing or resetting throughput using the AWS CLI

The following procedure shows how to use the AWS CLI to increase the number of transactions per second that Parameter Store can process for the current AWS account and AWS Region. You can also revert to the default limit.

### To increase Parameter Store throughput using the AWS CLI

1. Open the AWS CLI and run the following command to increase the transactions per second that Parameter Store can process in the current AWS account and AWS Region.

```
aws ssm update-service-setting --setting-id arn:aws:ssm:region:account-id:servicesetting/ssm/parameter-store/high-throughput-enabled --setting-value true
```

There is no output if the command succeeds.

2. Run the following command to view the current throughput service settings for Parameter Store in the current AWS account and AWS Region.

```
aws ssm get-service-setting --setting-id arn:aws:ssm:region:account-id:servicesetting/ssm/parameter-store/high-throughput-enabled
```

The system returns information similar to the following:

```
{
  "ServiceSetting": {
    "SettingId": "/ssm/parameter-store/high-throughput-enabled",
    "SettingValue": "true",
    "LastModifiedDate": 1556551683.923,
    "LastModifiedUser": "arn:aws:sts::123456789012:assumed-role/Administrator/Jasper",
    "ARN": "arn:aws:ssm:us-east-2:123456789012:servicesetting/ssm/parameter-store/high-throughput-enabled",
    "Status": "Customized"
  }
}
```

If you no longer need increased throughput, or if you no longer want to incur charges, you can revert to the standard settings. To revert your settings, run the following command.

```
aws ssm reset-service-setting --setting-id arn:aws:ssm:region:account-id:servicesetting/ssm/parameter-store/high-throughput-enabled
```

```
{
  "ServiceSetting": {
    "SettingId": "/ssm/parameter-store/high-throughput-enabled",
    "SettingValue": "false",
    "LastModifiedDate": 1555532818.578,
    "LastModifiedUser": "System",
    "ARN": "arn:aws:ssm:us-east-2:123456789012:servicesetting/ssm/parameter-store/high-throughput-enabled",
    "Status": "Default"
  }
}
```

```
}
```

## Increasing or resetting throughput (PowerShell)

The following procedure shows how to use the Tools for Windows PowerShell to increase the number of transactions per second that Parameter Store can process for the current AWS account and AWS Region. You can also revert to the default limit.

### To increase Parameter Store throughput using PowerShell

1. Increase Parameter Store throughput in the current AWS account and AWS Region using the AWS Tools for PowerShell (Tools for PowerShell).

```
Update-SSMServiceSetting -SettingId "arn:aws:ssm:region:account-id:servicesetting/ssm/parameter-store/high-throughput-enabled" -SettingValue "true" -Region region
```

There is no output if the command succeeds.

2. Run the following command to view the current throughput service settings for Parameter Store in the current AWS account and AWS Region.

```
Get-SSMServiceSetting -SettingId "arn:aws:ssm:region:account-id:servicesetting/ssm/parameter-store/high-throughput-enabled" -Region region
```

The systems returns information similar to the following:

```
ARN           : arn:aws:ssm:us-east-2:123456789012:servicesetting/ssm/parameter-store/high-throughput-enabled
LastModifiedDate : 4/29/2019 3:35:44 PM
LastModifiedUser  : arn:aws:sts::123456789012:assumed-role/Administrator/Jasper
SettingId        : /ssm/parameter-store/high-throughput-enabled
SettingValue     : true
Status          : Customized
```

If you no longer need increased throughput, or if you no longer want to incur charges, you can revert to the standard settings. To revert your settings, run the following command.

```
Reset-SSMServiceSetting -SettingId "arn:aws:ssm:region:account-id:servicesetting/ssm/parameter-store/high-throughput-enabled" -Region region
```

The system returns information similar to the following:

```
ARN                : arn:aws:ssm:us-east-2:123456789012:servicesetting/ssm/parameter-
store/high-throughput-enabled
LastModifiedDate  : 4/17/2019 8:26:58 PM
LastModifiedUser  : System
SettingId         : /ssm/parameter-store/high-throughput-enabled
SettingValue      : false
Status           : Default
```

## Setting up notifications or triggering actions based on Parameter Store events

The topics in this section explain how to use Amazon EventBridge and Amazon Simple Notification Service (Amazon SNS) to notify you about changes to AWS Systems Manager parameters. You can create an EventBridge rule to notify you when a parameter or a parameter label version is created, updated, or deleted. Events are emitted on a best effort basis. You can be notified about changes or status related to parameter policies, such as when a parameter expires, is going to expire, or hasn't changed for a specified period of time.

### Note

Parameter policies are available for parameters that use the advanced parameters tier. Charges apply. For more information, see [Assigning parameter policies in Parameter Store](#) and [Managing parameter tiers](#).

The topics in this section also explain how to initiate other actions on a target for specific parameter events. For example, you can run an AWS Lambda function to recreate a parameter automatically when it expires or is deleted. You can set up a notification to invoke a Lambda function when your database password is updated. The Lambda function can force your database connections to reset or reconnect with the new password. EventBridge also supports running Run Command commands and Automation executions, and actions in many other AWS services. Run Command and Automation are both capabilities of AWS Systems Manager. For more information, see the [Amazon EventBridge User Guide](#).

## Before You Begin

Create any resources you need to specify the target action for the rule you create. For example, if the rule you create is for sending a notification, first create an Amazon SNS topic. For more

information, see [Getting started with Amazon SNS](#) in the *Amazon Simple Notification Service Developer Guide*.

## Configuring EventBridge rules for parameters and parameter policies

This topic explains the following:

- How to create an EventBridge rule that invokes a target based on events that happen to one or more parameters in your AWS account.
- How to create EventBridge rules that invoke targets based on events that happen to one or more parameter policies in your AWS account. When you create an advanced parameter, you specify when a parameter expires, when to receive notification before a parameter expires, and how long to wait before notification should be sent that a parameter hasn't changed. You set up notification for these events using the following procedure. For more information, see [Assigning parameter policies in Parameter Store](#) and [Managing parameter tiers](#).

### To configure an EventBridge rule for a Systems Manager parameter or parameter policy

1. Open the Amazon EventBridge console at <https://console.aws.amazon.com/events/>.
2. In the navigation pane, choose **Rules**, and then choose **Create rule**.

-or-

If the EventBridge home page opens first, choose **Create rule**.

3. Enter a name and description for the rule.

A rule can't have the same name as another rule in the same Region and on the same event bus.

4. For **Event bus**, choose the event bus that you want to associate with this rule. If you want this rule to initiate on matching events that come from your own AWS account, select **default**. When an AWS service in your account emits an event, it always goes to your account's default event bus.
5. For **Rule type**, leave the default **Rule with an event pattern** selected.
6. Choose **Next**.
7. For **Event source**, leave the default **AWS events or EventBridge partner events** selected. You can skip the **Sample event** section.
8. For **Event pattern**, do the following:

- Choose **Custom patterns (JSON editor)**.
- For **Event pattern**, paste one of the following content in the box, depending on whether you are creating a rule for a parameter or a parameter policy:

#### Parameter

```
{
  "source": [
    "aws.ssm"
  ],
  "detail-type": [
    "Parameter Store Change"
  ],
  "detail": {
    "name": [
      "parameter-1-name",
      "/parameter-2-name/level-2",
      "/parameter-3-name/level-2/level-3"
    ],
    "operation": [
      "Create",
      "Update",
      "Delete",
      "LabelParameterVersion"
    ]
  }
}
```

#### Parameter policy

```
{
  "source": [
    "aws.ssm"
  ],
  "detail-type": [
    "Parameter Store Policy Action"
  ],
  "detail": {
    "parameter-name": [
      "parameter-1-name",
      "/parameter-2-name/level-2",
      "/parameter-3-name/level-2/level-3"
    ]
  }
}
```

```

    ],
    "policy-type": [
        "Expiration",
        "ExpirationNotification",
        "NoChangeNotification"
    ]
  }
}

```

- Modify the contents for the parameters and the operations you want to act on, as shown in the following samples.

### Parameter

With this example, an action is taken when either of the parameters named `/Oncall` and `/Project/Teamlead` are updated:

```

{
  "source": [
    "aws.ssm"
  ],
  "detail-type": [
    "Parameter Store Change"
  ],
  "detail": {
    "name": [
      "/Oncall",
      "/Project/Teamlead"
    ],
    "operation": [
      "Update"
    ]
  }
}

```

### Parameter policy

With this example, an action is taken whenever the parameter named `/OncallDuties` expires and is deleted:

```

{
  "source": [
    "aws.ssm"
  ]
}

```

```
    ],
    "detail-type": [
      "Parameter Store Policy Action"
    ],
    "detail": {
      "parameter-name": [
        "/OncallDuties"
      ],
      "policy-type": [
        "Expiration"
      ]
    }
  }
}
```

9. Choose **Next**.
10. For **Target 1**, choose a target type and a supported resource. For example, if you choose **SNS topic**, make a selection for **Topic**. If you choose **CodePipeline**, enter a pipeline ARN for **Pipeline ARN**. Provide additional configuration values as required.

 **Tip**

Choose **Add another target** if you require additional targets for the rule.

11. Choose **Next**.
12. (Optional) Enter one or more tags for the rule. For more information, see [Amazon EventBridge tags](#) in the *Amazon EventBridge User Guide*.
13. Choose **Next**.
14. Choose **Create rule**.

## Working with Parameter Store

This section describes how to organize and create tag parameters, and how to create different versions of parameters.

You can use the AWS Systems Manager console, the AWS Command Line Interface (AWS CLI), the AWS Tools for PowerShell, and the AWS SDKs to create and work with parameters. For more information about parameters, see [What is a parameter?](#).

### Topics

- [Creating Parameter Store parameters in Systems Manager](#)
- [Searching for Parameter Store parameters in Systems Manager](#)

- [Preventing access to Parameter Store API operations](#)
- [Working with parameter labels in Parameter Store](#)
- [Working with parameter versions in Parameter Store](#)
- [Working with shared parameters in Parameter Store](#)
- [Working with parameters in Parameter Store using Run Command commands](#)
- [Using native parameter support in Parameter Store for Amazon Machine Image IDs](#)
- [Deleting parameters from Parameter Store](#)

### Creating Parameter Store parameters in Systems Manager

Use the information in the following topics to help you create Systems Manager parameters using the AWS Systems Manager console, the AWS Command Line Interface (AWS CLI), or AWS Tools for Windows PowerShell (Tools for Windows PowerShell).

This section demonstrates how to create, store, and run parameters with Parameter Store in a test environment. It also demonstrates how to use Parameter Store with other Systems Manager capabilities and AWS services. For more information, see [What is a parameter?](#)

### Understanding requirements and constraints for parameter names

Use the information in this topic to help you specify valid values for parameter names when you create a parameter.

This information supplements the details in the topic [PutParameter](#) in the *AWS Systems Manager API Reference*, which also provides information about the values **AllowedPattern**, **Description**, **KeyId**, **Overwrite**, **Type**, and **Value**.

The requirements and constraints for parameter names include the following:

- **Case sensitivity:** Parameter names are case sensitive.
- **Spaces:** Parameter names can't include spaces.
- **Valid characters:** Parameter names can consist of the following symbols and letters only: a-z A-Z 0-9 \_ . -

In addition, the slash character ( / ) is used to delineate hierarchies in parameter names. For example: /Dev/Production/East/Project-ABC/MyParameter

- **Valid AMI format:** When you choose `aws:ec2:image` as the data type for a String parameter, the ID you enter must validate for the AMI ID format `ami-12345abcdeEXAMPLE`.
- **Fully qualified:** When you create or reference a parameter in a hierarchy, include a leading forward slash character ( / ) . When you reference a parameter that is part of a hierarchy, specify the entire hierarchy path including the initial slash ( / ).
  - Fully qualified parameter names: `MyParameter1`, `/MyParameter2`, `/Dev/Production/East/Project-ABC/MyParameter`
  - Not fully qualified parameter name: `MyParameter3/L1`
- **Length:** The maximum length for a parameter name that you create is 1011 characters. This includes the characters in the ARN that precede the name you specify, such as `arn:aws:ssm:us-east-2:111122223333:parameter/`.
- **Prefixes:** A parameter name can't be prefixed with "aws" or "ssm" (case-insensitive). For example, attempts to create parameters with the following names fail with an exception:
  - `awsTestParameter`
  - `SSM-testparameter`
  - `/aws/testparam1`

#### Note

When you specify a parameter in an SSM document, command, or script, include `ssm` as part of the syntax. For example, `{{ssm:parameter-name}}` and `{{ ssm:parameter-name }}`, such as `{{ssm:MyParameter}}`, and `{{ ssm:MyParameter }}`.

- **Uniqueness:** A parameter name must be unique within an AWS Region. For example, Systems Manager treats the following as separate parameters, if they exist in the same Region:

- /Test/TestParam1
- /TestParam1

The following examples are also unique:

- /Test/TestParam1/Logpath1
- /Test/TestParam1

The following examples, however, if in the same Region, aren't unique:

- /TestParam1
- TestParam1
- **Hierarchy depth:** If you specify a parameter hierarchy, the hierarchy can have a maximum depth of fifteen levels. You can define a parameter at any level of the hierarchy. Both of the following examples are structurally valid:
  - /Level-1/L2/L3/L4/L5/L6/L7/L8/L9/L10/L11/L12/L13/L14/parameter-name
  - parameter-name

Attempting to create the following parameter would fail with a `HierarchyLevelLimitExceededException` exception:

- /Level-1/L2/L3/L4/L5/L6/L7/L8/L9/L10/L11/L12/L13/L14/L15/L16/parameter-name

### Important

If a user has access to a path, then the user can access all levels of that path. For example, if a user has permission to access path /a, then the user can also access /a/b. Even if a user has explicitly been denied access in AWS Identity and Access Management (IAM) for parameter /a/b, they can still call the [GetParametersByPath](#) API operation recursively for /a and view /a/b.

## Topics

- [Creating a Parameter Store parameter using the console](#)
- [Creating a Parameter Store parameter using the AWS CLI](#)

- [Creating a Parameter Store parameter using Tools for Windows PowerShell](#)

## Creating a Parameter Store parameter using the console

You can use the AWS Systems Manager console to create and run `String`, `StringList`, and `SecureString` parameter types. After deleting a parameter, wait for at least 30 seconds to create a parameter with the same name.

### Note

Parameters are only available in the AWS Region where they were created.

The following procedure walks you through the process of creating a parameter in the Parameter Store console. You can create `String`, `StringList`, and `SecureString` parameter types from the console.

### To create a parameter

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Parameter Store**.
3. Choose **Create parameter**.
4. In the **Name** box, enter a hierarchy and a name. For example, enter `/Test/helloWorld`.

For more information about parameter hierarchies, see [Working with parameter hierarchies in Parameter Store](#).

5. In the **Description** box, type a description that identifies this parameter as a test parameter.
6. For **Parameter tier** choose either **Standard** or **Advanced**. For more information about advanced parameters, see [Managing parameter tiers](#).
7. For **Type**, choose **String**, **StringList**, or **SecureString**.
  - If you choose **String**, the **Data type** field is displayed. If you're creating a parameter to hold the resource ID for an Amazon Machine Image (AMI), select `aws:ec2:image`. Otherwise, keep the default text selected.
  - If you choose **SecureString**, the **KMS Key ID** field is displayed. If you don't provide an AWS Key Management Service AWS KMS key ID, an AWS KMS key Amazon Resource Name (ARN),

an alias name, or an alias ARN, then the system uses `alias/aws/ssm`, which is the AWS managed key for Systems Manager. If you don't want to use this key, then you can use a customer managed key. For more information about AWS managed keys and customer managed keys, see [AWS Key Management Service Concepts](#) in the *AWS Key Management Service Developer Guide*. For more information about Parameter Store and AWS KMS encryption, see [How AWS Systems Manager Parameter Store Uses AWS KMS](#).

### Important

Parameter Store only supports [symmetric encryption KMS keys](#). You can't use an [asymmetric encryption KMS key](#) to encrypt your parameters. For help determining whether a KMS key is symmetric or asymmetric, see [Identifying symmetric and asymmetric KMS keys](#) in the *AWS Key Management Service Developer Guide*

- When creating a `SecureString` parameter in the console by using the `key-id` parameter with either a customer managed key alias name or an alias ARN, specify the prefix `alias/` before the alias. Following is an ARN example.

```
arn:aws:kms:us-east-2:123456789012:alias/abcd1234-ab12-cd34-ef56-abcdeEXAMPLE
```

Following is an alias name example.

```
alias/MyAliasName
```

8. In the **Value** box, type a value. For example, type **This is my first parameter** or **ami-0dbf5ea29aEXAMPLE**.

### Note

Parameters can't be referenced or nested in the values of other parameters. You can't include `{{}}` or `{{ssm:parameter-name}}` in a parameter value.

If you chose **SecureString**, the value of the parameter is masked by default ("\*\*\*\*\*") when you view it later on the parameter **Overview** tab, as shown in the following illustration. Choose **Show** to display the parameter value.

9. (Optional) In the **Tags** area, apply one or more tag key-value pairs to the parameter.

Tags are optional metadata that you assign to a resource. Tags allow you to categorize a resource in different ways, such as by purpose, owner, or environment. For example, you might want to tag a Systems Manager parameter to identify the type of resource to which it applies, the environment, or the type of configuration data referenced by the parameter. In this case, you could specify the following key-value pairs:

- Key=Resource, Value=S3bucket
- Key=OS, Value=Windows
- Key=ParameterType, Value=LicenseKey

10. Choose **Create parameter**.

11. In the parameters list, choose the name of the parameter you just created. Verify the details on the **Overview** tab. If you created a SecureString parameter, choose **Show** to view the unencrypted value.

#### **Note**

You can't change an advanced parameter to a standard parameter. If you no longer need an advanced parameter, or if you no longer want to incur charges for an advanced parameter, delete it and recreate it as a new standard parameter.

## Creating a Parameter Store parameter using the AWS CLI

You can use the AWS Command Line Interface (AWS CLI) to create String, StringList, and SecureString parameter types. After deleting a parameter, wait for at least 30 seconds to create a parameter with the same name.

Parameters can't be referenced or nested in the values of other parameters. You can't include `{{}}` or `{{ssm:parameter-name}}` in a parameter value.

### Note

Parameters are only available in the AWS Region where they were created.

## Topics

- [Creating a String parameter using the AWS CLI](#)
- [Creating a StringList parameter using the AWS CLI](#)
- [Creating a SecureString parameter using the AWS CLI](#)
- [Creating a multi-line parameter using the AWS CLI](#)

## Creating a String parameter using the AWS CLI

1. Install and configure the AWS Command Line Interface (AWS CLI), if you haven't already.

For information, see [Installing or updating the latest version of the AWS CLI](#).

2. Run the following command to create a String-type parameter. Replace each *example resource placeholder* with your own information.

### Linux & macOS

```
aws ssm put-parameter \  
  --name "parameter-name" \  
  --value "parameter-value" \  
  --type String \  
  --tags "Key=tag-key,Value=tag-value"
```

### Windows

```
aws ssm put-parameter ^  
  --name "parameter-name" ^  
  --value "parameter-value" ^  
  --type String ^  
  --tags "Key=tag-key,Value=tag-value"
```

-or-

Run the following command to create a parameter that contains an Amazon Machine Image (AMI) ID as the parameter value.

### Linux & macOS

```
aws ssm put-parameter \  
  --name "parameter-name" \  
  --value "an-AMI-id" \  
  --type String \  
  --data-type "aws:ec2:image" \  
  --tags "Key=tag-key,Value=tag-value"
```

### Windows

```
aws ssm put-parameter ^  
  --name "parameter-name" ^  
  --value "an-AMI-id" ^  
  --type String ^  
  --data-type "aws:ec2:image" ^  
  --tags "Key=tag-key,Value=tag-value"
```

The `--name` option supports hierarchies. For information about hierarchies, see [Working with parameter hierarchies in Parameter Store](#).

The `--data-type` option must be specified only if you are creating a parameter that contains an AMI ID. It validates that the parameter value you enter is a properly formatted Amazon Elastic Compute Cloud (Amazon EC2) AMI ID. For all other parameters, the default data type is text and it's optional to specify a value. For more information, see [Using native parameter support in Parameter Store for Amazon Machine Image IDs](#).

#### Important

If successful, the command returns the version number of the parameter. **Exception:** If you have specified `aws:ec2:image` as the data type, a new version number in the response doesn't mean that the parameter value has been validated yet. For more

information, see [Using native parameter support in Parameter Store for Amazon Machine Image IDs](#).

The following example adds two key-value pair tags to a parameter.

## Linux & macOS

```
aws ssm put-parameter \  
  --name parameter-name \  
  --value "parameter-value" \  
  --type "String" \  
  --tags '[{"Key":"Region","Value":"East"}, {"Key":"Environment",  
"Value":"Production"}]'
```

## Windows

```
aws ssm put-parameter ^  
  --name parameter-name ^  
  --value "parameter-value" ^  
  --type "String" ^  
  --tags [{"Key\\":\\"Region1\\",\\"Value\\":\\"East1\\"}, {"Key\\":\\"Environment1\\",  
\\"Value\\":\\"Production1\\"}]
```

The following example uses a parameter hierarchy in the name to create a plaintext String parameter. It returns the version number of the parameter. For more information about parameter hierarchies, see [Working with parameter hierarchies in Parameter Store](#).

## Linux & macOS

### Parameter not in a hierarchy

```
aws ssm put-parameter \  
  --name "golden-ami" \  
  --type "String" \  
  --value "ami-12345abcdeEXAMPLE"
```

### Parameter in a hierarchy

```
aws ssm put-parameter \  
  --name "/amis/linux/golden-ami" \  
  --type "String" \  
  --value "ami-12345abcdeEXAMPLE"
```

## Windows

### Parameter not in a hierarchy

```
aws ssm put-parameter ^  
  --name "golden-ami" ^  
  --type "String" ^  
  --value "ami-12345abcdeEXAMPLE"
```

### Parameter in a hierarchy

```
aws ssm put-parameter ^  
  --name "/amis/windows/golden-ami" ^  
  --type "String" ^  
  --value "ami-12345abcdeEXAMPLE"
```

3. Run the following command to view the latest parameter value and verify the details of your new parameter.

```
aws ssm get-parameters --names "/Test/IAD/helloWorld"
```

The system returns information like the following.

```
{  
  "InvalidParameters": [],  
  "Parameters": [  
    {  
      "Name": "/Test/IAD/helloWorld",  
      "Type": "String",  
      "Value": "My updated parameter value",  
      "Version": 2,  
      "LastModifiedDate": "2020-02-25T15:55:33.677000-08:00",  
      "ARN": "arn:aws:ssm:us-east-2:123456789012:parameter/Test/IAD/  
helloWorld"  
    }  
  ]  
}
```

```
]
}
```

Run the following command to change the parameter value. It returns the version number of the parameter.

```
aws ssm put-parameter --name "/Test/IAD/helloWorld" --value "My updated 1st parameter"
--type String --overwrite
```

Run the following command to view the parameter value history.

```
aws ssm get-parameter-history --name "/Test/IAD/helloWorld"
```

Run the following command to use this parameter in a command.

```
aws ssm send-command --document-name "AWS-RunShellScript" --parameters '{"commands":
["echo {{ssm:/Test/IAD/helloWorld}}"]}' --targets "Key=instanceids,Values=instance-ids"
```

Run the following command if you only want to retrieve the parameter Value.

```
aws ssm get-parameter --name testDataTypeParameter --query "Parameter.Value"
```

Run the following command if you only want to retrieve the parameter Value using get-parameters.

```
aws ssm get-parameters --names "testDataTypeParameter" --query "Parameters[*].Value"
```

Run the following command to view the parameter metadata.

```
aws ssm describe-parameters --filters "Key=Name,Values=/Test/IAD/helloWorld"
```

 **Note**

*Name* must be capitalized.

The system returns information like the following.

```
{
  "Parameters": [
    {
      "Name": "helloworld",
      "Type": "String",
      "LastModifiedUser": "arn:aws:iam::123456789012:user/JohnDoe",
      "LastModifiedDate": 1494529763.156,
      "Version": 1,
      "Tier": "Standard",
      "Policies": []
    }
  ]
}
```

## Creating a StringList parameter using the AWS CLI

1. Install and configure the AWS Command Line Interface (AWS CLI), if you haven't already.

For information, see [Installing or updating the latest version of the AWS CLI](#).

2. Run the following command to create a parameter. Replace each *example resource placeholder* with your own information.

### Linux & macOS

```
aws ssm put-parameter \
  --name "parameter-name" \
  --value "a-comma-separated-list-of-values" \
  --type StringList \
  --tags "Key=tag-key,Value=tag-value"
```

### Windows

```
aws ssm put-parameter ^
  --name "parameter-name" ^
  --value "a-comma-separated-list-of-values" ^
  --type StringList ^
  --tags "Key=tag-key,Value=tag-value"
```

**Note**

If successful, the command returns the version number of the parameter.

This example adds two key-value pair tags to a parameter. (Depending on the operating system type on your local machine, run one of the following commands. The version to run from a local Windows machine includes the escape characters ("\\") that you need to run the command from your command line tool.)

Here is a `StringList` example that uses a parameter hierarchy.

**Linux & macOS**

```
aws ssm put-parameter \  
  --name /IAD/ERP/Oracle/addUsers \  
  --value "Milana,Mariana,Mark,Miguel" \  
  --type StringList
```

**Windows**

```
aws ssm put-parameter ^  
  --name /IAD/ERP/Oracle/addUsers ^  
  --value "Milana,Mariana,Mark,Miguel" ^  
  --type StringList
```

**Note**

Items in a `StringList` must be separated by a comma (.). You can't use other punctuation or special characters to escape items in the list. If you have a parameter value that requires a comma, then use the `String` type.

3. Run the `get-parameters` command to verify the details of the parameter. For example:

```
aws ssm get-parameters --name "/IAD/ERP/Oracle/addUsers"
```

## Creating a SecureString parameter using the AWS CLI

Use the following procedure to create a SecureString parameter. Replace each *example resource placeholder* with your own information.

### Important

Only the *value* of a SecureString parameter is encrypted. Parameter names, descriptions, and other properties aren't encrypted.

### Important

Parameter Store only supports [symmetric encryption KMS keys](#). You can't use an [asymmetric encryption KMS key](#) to encrypt your parameters. For help determining whether a KMS key is symmetric or asymmetric, see [Identifying symmetric and asymmetric KMS keys](#) in the *AWS Key Management Service Developer Guide*

1. Install and configure the AWS Command Line Interface (AWS CLI), if you haven't already.  
For information, see [Installing or updating the latest version of the AWS CLI](#).
2. Run **one** of the following commands to create a parameter that uses the SecureString data type.

Linux & macOS

### Create a SecureString parameter using the default AWS managed key

```
aws ssm put-parameter \  
  --name "parameter-name" \  
  --value "parameter-value" \  
  --type "SecureString"
```

### Create a SecureString parameter that uses a customer managed key

```
aws ssm put-parameter \  
  --name "parameter-name" \  
  --value "a-parameter-value, for example P@ssW%rd#1" \  
  --type "SecureString"
```

```
--tags "Key=tag-key,Value=tag-value"
```

## Create a SecureString parameter that uses a custom AWS KMS key

```
aws ssm put-parameter \  
  --name "parameter-name" \  
  --value "a-parameter-value, for example P@ssW%rd#1" \  
  --type "SecureString" \  
  --key-id "your-account-ID/the-custom-AWS KMS-key" \  
  --tags "Key=tag-key,Value=tag-value"
```

## Windows

### Create a SecureString parameter using the default AWS managed key

```
aws ssm put-parameter ^  
  --name "parameter-name" ^  
  --value "parameter-value" ^  
  --type "SecureString"
```

### Create a SecureString parameter that uses a customer managed key

```
aws ssm put-parameter ^  
  --name "parameter-name" ^  
  --value "a-parameter-value, for example P@ssW%rd#1" ^  
  --type "SecureString" ^  
  --tags "Key=tag-key,Value=tag-value"
```

### Create a SecureString parameter that uses a custom AWS KMS key

```
aws ssm put-parameter ^  
  --name "parameter-name" ^  
  --value "a-parameter-value, for example P@ssW%rd#1" ^  
  --type "SecureString" ^  
  --key-id " ^  
  --tags "Key=tag-key,Value=tag-valueaccount-ID/the-custom-AWS KMS-key"
```

If you create a SecureString parameter by using the AWS managed key key in your account and Region, then you *don't* have to provide a value for the `--key-id` parameter.

**Note**

To use the AWS KMS key assigned to your AWS account and AWS Region, remove the `key-id` parameter from the command. For more information about AWS KMS keys, see [AWS Key Management Service Concepts](#) in the *AWS Key Management Service Developer Guide*.

To use a customer managed key instead of the AWS managed key assigned to your account, specify the key by using the `--key-id` parameter. The parameter supports the following KMS parameter formats.

- Key Amazon Resource Name (ARN) example:

```
arn:aws:kms:us-east-2:123456789012:key/key-id
```

- Alias ARN example:

```
arn:aws:kms:us-east-2:123456789012:alias/alias-name
```

- Key ID example:

```
12345678-1234-1234-1234-123456789012
```

- Alias Name example:

```
alias/MyAliasName
```

You can create a customer managed key by using the AWS Management Console or the AWS KMS API. The following AWS CLI commands create a customer managed key in the current AWS Region of your AWS account.

```
aws kms create-key
```

Use a command in the following format to create a `SecureString` parameter using the key you just created.

The following example uses an obfuscated name (313vat3131) for a password parameter and an AWS KMS key.

## Linux & macOS

```
aws ssm put-parameter \  
  --name /Finance/Payroll/313vat3131 \  
  --value "P@sSw)rd" \  
  --type SecureString \  
  --key-id arn:aws:kms:us-  
east-2:123456789012:key/1a2b3c4d-1a2b-1a2b-1a2b-1a2b3c4d5e
```

## Windows

```
aws ssm put-parameter ^  
  --name /Finance/Payroll/313vat3131 ^  
  --value "P@sSw)rd" ^  
  --type SecureString ^  
  --key-id arn:aws:kms:us-  
east-2:123456789012:key/1a2b3c4d-1a2b-1a2b-1a2b-1a2b3c4d5e
```

3. Run the following command to verify the details of the parameter.

If you don't specify the `with-decryption` parameter, or if you specify the `no-with-decryption` parameter, the command returns an encrypted GUID.

## Linux & macOS

```
aws ssm get-parameters \  
  --name "the-parameter-name-you-specified" \  
  --with-decryption
```

## Windows

```
aws ssm get-parameters ^  
  --name "the-parameter-name-you-specified" ^  
  --with-decryption
```

4. Run the following command to view the parameter metadata.

## Linux & macOS

```
aws ssm describe-parameters \  
  --parameter /Finance/Payroll/313vat3131
```

```
--filters "Key=Name,Values=the-name-that-you-specified"
```

## Windows

```
aws ssm describe-parameters ^  
  --filters "Key=Name,Values=the-name-that-you-specified"
```

5. Run the following command to change the parameter value if you're **not** using a customer managed AWS KMS key.

## Linux & macOS

```
aws ssm put-parameter \  
  --name "the-name-that-you-specified" \  
  --value "a-new-parameter-value" \  
  --type "SecureString" \  
  --overwrite
```

## Windows

```
aws ssm put-parameter ^  
  --name "the-name-that-you-specified" ^  
  --value "a-new-parameter-value" ^  
  --type "SecureString" ^  
  --overwrite
```

-or-

Run one of the following commands to change the parameter value if you **are** using a customer managed AWS KMS key.

## Linux & macOS

```
aws ssm put-parameter \  
  --name "the-name-that-you-specified" \  
  --value "a-new-parameter-value" \  
  --type "SecureString" \  
  --key-id "the-KMSkey-ID" \  
  --overwrite
```

```
aws ssm put-parameter \  
  --name "the-name-that-you-specified" \  
  --value "a-new-parameter-value" \  
  --type "SecureString" \  
  --key-id "account-alias/the-KMSkey-ID" \  
  --overwrite
```

## Windows

```
aws ssm put-parameter ^  
  --name "the-name-that-you-specified" ^  
  --value "a-new-parameter-value" ^  
  --type "SecureString" ^  
  --key-id "the-KMSkey-ID" ^  
  --overwrite
```

```
aws ssm put-parameter ^  
  --name "the-name-that-you-specified" ^  
  --value "a-new-parameter-value" ^  
  --type "SecureString" ^  
  --key-id "account-alias/the-KMSkey-ID" ^  
  --overwrite
```

6. Run the following command to view the latest parameter value.

## Linux & macOS

```
aws ssm get-parameters \  
  --name "the-name-that-you-specified" \  
  --with-decryption
```

## Windows

```
aws ssm get-parameters ^  
  --name "the-name-that-you-specified" ^  
  --with-decryption
```

7. Run the following command to view the parameter value history.

## Linux & macOS

```
aws ssm get-parameter-history \  
  --name "the-name-that-you-specified"
```

## Windows

```
aws ssm get-parameter-history ^  
  --name "the-name-that-you-specified"
```

### Note

You can manually create a parameter with an encrypted value. In this case, because the value is already encrypted, you don't have to choose the SecureString parameter type. If you do choose SecureString, your parameter is doubly encrypted.

By default, all SecureString values are displayed as cipher-text. To decrypt a SecureString value, a user must have permission to call the AWS KMS [Decrypt](#) API operation. For information about configuring AWS KMS access control, see [Authentication and Access Control for AWS KMS](#) in the *AWS Key Management Service Developer Guide*.

### Important

If you change the KMS key alias for the KMS key used to encrypt a parameter, then you must also update the key alias the parameter uses to reference AWS KMS. This only applies to the KMS key alias; the key ID that an alias attaches to stays the same unless you delete the whole key.

## Creating a multi-line parameter using the AWS CLI

You can use the AWS CLI to create a parameter with line breaks. Use line breaks to break up the text in longer parameter values for better legibility or, for example, update multi-paragraph parameter content for a web page. You can include the content in a JSON file and use the `--cli-input-json` option, using line break characters like `\n`, as shown in the following example.

1. Install and configure the AWS Command Line Interface (AWS CLI), if you haven't already.

For information, see [Installing or updating the latest version of the AWS CLI](#).

2. Run the following command to create a multi-line parameter.

#### Linux & macOS

```
aws ssm put-parameter \  
  --name "MultiLineParameter" \  
  --type String \  
  --cli-input-json file://MultiLineParameter.json
```

#### Windows

```
aws ssm put-parameter ^  
  --name "MultiLineParameter" ^  
  --type String ^  
  --cli-input-json file://MultiLineParameter.json
```

The following example shows the contents of the file `MultiLineParameter.json`.

```
{  
  "Value": "<para>Paragraph One</para>\n<para>Paragraph Two</para>  
\n<para>Paragraph Three</para>"  
}
```

The saved parameter value is stored as follows.

```
<para>Paragraph One</para>  
<para>Paragraph Two</para>  
<para>Paragraph Three</para>
```

### Creating a Parameter Store parameter using Tools for Windows PowerShell

You can use AWS Tools for Windows PowerShell to create `String`, `StringList`, and `SecureString` parameter types. After deleting a parameter, wait for at least 30 seconds to create a parameter with the same name.

Parameters can't be referenced or nested in the values of other parameters. You can't include `{{}}` or `{{ssm:parameter-name}}` in a parameter value.

### Note

Parameters are only available in the AWS Region where they were created.

## Topics

- [Creating a String parameter \(Tools for Windows PowerShell\)](#)
- [Creating a StringList parameter \(Tools for Windows PowerShell\)](#)
- [Creating a SecureString parameter \(Tools for Windows PowerShell\)](#)

## Creating a String parameter (Tools for Windows PowerShell)

1. Install and configure the AWS Tools for PowerShell (Tools for Windows PowerShell), if you haven't already.

For information, see [Installing the AWS Tools for PowerShell](#).

2. Run the following command to create a parameter that contains a plain text value. Replace each *example resource placeholder* with your own information.

```
Write-SSMParameter `
  -Name "parameter-name" `
  -Value "parameter-value" `
  -Type "String"
```

-or-

Run the following command to create a parameter that contains an Amazon Machine Image (AMI) ID as the parameter value.

### Note

To create a parameter with a tag, create the `service.model.tag` before hand as a variable. Here is an example.

```
$tag = New-Object Amazon.SimpleSystemsManagement.Model.Tag
```

```
$tag.Key = "tag-key"
$tag.Value = "tag-value"
```

```
Write-SSMParameter `
  -Name "parameter-name" `
  -Value "an-AMI-id" `
  -Type "String" `
  -DataType "aws:ec2:image" `
  -Tags $tag
```

The `-DataType` option must be specified only if you are creating a parameter that contains an AMI ID. For all other parameters, the default data type is text. For more information, see [Using native parameter support in Parameter Store for Amazon Machine Image IDs](#).

Here is an example that uses a parameter hierarchy.

```
Write-SSMParameter `
  -Name "/IAD/Web/SQL/IPaddress" `
  -Value "99.99.99.999" `
  -Type "String" `
  -Tags $tag
```

3. Run the following command to verify the details of the parameter.

```
(Get-SSMParameterValue -Name "the-parameter-name-you-specified").Parameters
```

## Creating a StringList parameter (Tools for Windows PowerShell)

1. Install and configure the AWS Tools for PowerShell (Tools for Windows PowerShell), if you haven't already.

For information, see [Installing the AWS Tools for PowerShell](#).

2. Run the following command to create a StringList parameter. Replace each *example resource placeholder* with your own information.

**Note**

To create a parameter with a tag, create the `service.model.tag` before hand as a variable. Here is an example.

```
$tag = New-Object Amazon.SimpleSystemsManagement.Model.Tag
$tag.Key = "tag-key"
$tag.Value = "tag-value"
```

```
Write-SSMParameter `
  -Name "parameter-name" `
  -Value "a-comma-separated-list-of-values" `
  -Type "StringList" `
  -Tags $tag
```

If successful, the command returns the version number of the parameter.

Here is an example.

```
Write-SSMParameter `
  -Name "stringlist-parameter" `
  -Value "Milana,Mariana,Mark,Miguel" `
  -Type "StringList" `
  -Tags $tag
```

**Note**

Items in a `StringList` must be separated by a comma (,). You can't use other punctuation or special characters to escape items in the list. If you have a parameter value that requires a comma, then use the `String` type.

3. Run the following command to verify the details of the parameter.

```
(Get-SSMParameterValue -Name "the-parameter-name-you-specified").Parameters
```

## Creating a SecureString parameter (Tools for Windows PowerShell)

Before you create a SecureString parameter, read about the requirements for this type of parameter. For more information, see [Creating a SecureString parameter using the AWS CLI](#).

### Important

Only the *value* of a SecureString parameter is encrypted. Parameter names, descriptions, and other properties aren't encrypted.

### Important

Parameter Store only supports [symmetric encryption KMS keys](#). You can't use an [asymmetric encryption KMS key](#) to encrypt your parameters. For help determining whether a KMS key is symmetric or asymmetric, see [Identifying symmetric and asymmetric KMS keys](#) in the *AWS Key Management Service Developer Guide*

1. Install and configure the AWS Tools for PowerShell (Tools for Windows PowerShell), if you haven't already.

For information, see [Installing the AWS Tools for PowerShell](#).

2. Run the following command to create a parameter. Replace each *example resource placeholder* with your own information.

### Note

To create a parameter with a tag, first create the `service.model.tag` as a variable. Here is an example.

```
$tag = New-Object Amazon.SimpleSystemsManagement.Model.Tag
$tag.Key = "tag-key"
$tag.Value = "tag-value"
```

```
Write-SSMParameter `
  -Name "parameter-name" `
```

```
-Value "parameter-value" `
-Type "SecureString" `
-KeyId "an AWS KMS key ID, an AWS KMS key ARN, an alias name, or an alias ARN"
`
-Tags $tag
```

If successful, the command returns the version number of the parameter.

### Note

To use the AWS managed key assigned to your account, remove the `-KeyId` parameter from the command.

Here is an example that uses an obfuscated name (3l3vat3131) for a password parameter and an AWS managed key.

```
Write-SSMParameter `
  -Name "/Finance/Payroll/3l3vat3131" `
  -Value "P@sSwW)rd" `
  -Type "SecureString" `
  -Tags $tag
```

3. Run the following command to verify the details of the parameter.

```
(Get-SSMParameterValue -Name "the-parameter-name-you-specified" -WithDecryption
$true).Parameters
```

By default, all `SecureString` values are displayed as cipher-text. To decrypt a `SecureString` value, a user must have permission to call the AWS KMS [Decrypt](#) API operation. For information about configuring AWS KMS access control, see [Authentication and Access Control for AWS KMS](#) in the *AWS Key Management Service Developer Guide*.

### Important

If you change the KMS key alias for the KMS key used to encrypt a parameter, then you must also update the key alias the parameter uses to reference AWS KMS. This only applies

to the KMS key alias; the key ID that an alias attaches to stays the same unless you delete the whole key.

## Searching for Parameter Store parameters in Systems Manager

When you have a lot of parameters in your account, it can be difficult to find information about a single or several parameters at a time. In this case, you can use filter tools to search for the ones you need information about, according to search criteria you specify. You can use the AWS Systems Manager console, the AWS Command Line Interface (AWS CLI), the AWS Tools for PowerShell, or the [DescribeParameters](#) API to search for parameters.

### Topics

- [Searching for a parameter using the console](#)
- [Searching for a parameter using the AWS CLI](#)

### Searching for a parameter using the console

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Parameter Store**.
3. Select in the search box and choose how you want to search. For example, Type or Name.
4. Provide information for the search type you selected. For example:
  - If you're searching by Type, choose from String, StringList, or SecureString.
  - If you're searching by Name, choose contains, equals, or begins-with, and then enter all or part of a parameter name.

#### Note

In the console, the default search type for Name is contains.

5. Press **Enter**.

The list of parameters is updated with the results of your search.

## Searching for a parameter using the AWS CLI

Use the `describe-parameters` command to view information about one or more parameters in the AWS CLI.

The following examples demonstrate various options you can use to view information about the parameters in your AWS account. For more information about these options, see [describe-parameters](#) in the *AWS Command Line Interface User Guide*.

1. Install and configure the AWS Command Line Interface (AWS CLI), if you haven't already.

For information, see [Installing or updating the latest version of the AWS CLI](#).

2. Replace the sample values in the following commands with values reflecting parameters that have been created in your account.

### Linux & macOS

```
aws ssm describe-parameters \  
  --parameter-filters "Key=Name,Values=MyParameterName"
```

### Windows

```
aws ssm describe-parameters ^  
  --parameter-filters "Key=Name,Values=MyParameterName"
```

#### Note

For `describe-parameters`, the default search type for Name is Equals. In your parameter filters, specifying `"Key=Name,Values=MyParameterName"` is the same as specifying `"Key=Name,Option=Equals,Values=MyParameterName"`.

```
aws ssm describe-parameters \  
  --parameter-filters "Key=Name,Option=Contains,Values=Product"
```

```
aws ssm describe-parameters \  
  --parameter-filters "Key=Type,Values=String"
```

```
aws ssm describe-parameters \  
  --parameter-filters "Key=Path,Values=/Production/West"
```

```
aws ssm describe-parameters \  
  --parameter-filters "Key=Tier,Values=Standard"
```

```
aws ssm describe-parameters \  
  --parameter-filters "Key=tag:tag-key,Values=tag-value"
```

```
aws ssm describe-parameters \  
  --parameter-filters "Key=KeyId,Values=key-id"
```

### Note

In the last example, *key-id* represents the ID of an AWS Key Management Service (AWS KMS) key used to encrypt a SecureString parameter created in your account. Alternatively, you can enter **alias/aws/ssm** to use the default AWS KMS key for your account. For more information, see [Creating a SecureString parameter using the AWS CLI](#).

If successful, the command returns output similar to the following.

```
{  
  "Parameters": [  
    {  
      "Name": "/Production/West/Manager",  
      "Type": "String",  
      "LastModifiedDate": 1573438580.703,  
      "LastModifiedUser": "arn:aws:iam::111122223333:user/Mateo.Jackson",  
      "Version": 1,  
      "Tier": "Standard",  
      "Policies": []  
    },  
    {  
      "Name": "/Production/West/TeamLead",  
      "Type": "String",  
      "LastModifiedDate": 1572363610.175,
```

```
    "LastModifiedUser": "arn:aws:iam::111122223333:user/Mateo.Jackson",
    "Version": 1,
    "Tier": "Standard",
    "Policies": []
  },
  {
    "Name": "/Production/West/HR",
    "Type": "String",
    "LastModifiedDate": 1572363680.503,
    "LastModifiedUser": "arn:aws:iam::111122223333:user/Mateo.Jackson",
    "Version": 1,
    "Tier": "Standard",
    "Policies": []
  }
]
```

## Assigning parameter policies in Parameter Store

Parameter policies help you manage a growing set of parameters by allowing you to assign specific criteria to a parameter such as an expiration date or *time to live*. Parameter policies are especially helpful in forcing you to update or delete passwords and configuration data stored in Parameter Store, a capability of AWS Systems Manager. Parameter Store offers the following types of policies: Expiration, ExpirationNotification, and NoChangeNotification.

### Note

To implement password rotation lifecycles, use AWS Secrets Manager. You can rotate, manage, and retrieve database credentials, API keys, and other secrets throughout their lifecycle using Secrets Manager. For more information, see [What is AWS Secrets Manager?](#) in the *AWS Secrets Manager User Guide*.

Parameter Store enforces parameter policies by using asynchronous, periodic scans. After you create a policy, you don't need to perform additional actions to enforce the policy. Parameter Store independently performs the action defined by the policy according to the criteria you specified.

**Note**

Parameter policies are available for parameters that use the advanced parameters tier. For more information, see [Managing parameter tiers](#).

A parameter policy is a JSON array, as shown in the following table. You can assign a policy when you create a new advanced parameter, or you can apply a policy by updating a parameter. Parameter Store supports the following types of parameter policies.

| Policy            | Details  | Examples  |
|-------------------|--|---|
| <b>Expiration</b> | <p>This policy deletes the parameter. You can specify a specific date and time by using either the <code>ISO_INSTANT</code> format or the <code>ISO_OFFSET_DATE_TIME</code> format. To change when you want the parameter to be deleted, update the policy. Updating a <i>parameter</i> doesn't affect the expiration date or time of the policy attached to it. When the expiration date and time is reached, Parameter Store deletes the parameter.</p> <div data-bbox="591 1507 1029 1879" style="border: 1px solid #add8e6; border-radius: 10px; padding: 10px; margin-top: 10px;"> <p><b>Note</b></p> <p>This example uses the <code>ISO_INSTANT</code> format. You can also specify a date and time by using the <code>ISO_OFFSE</code></p> </div> | <pre data-bbox="1068 709 1507 1150"> {   "Type": "Expiration",   "Version": "1.0",   "Attributes": {     "Timestamp":       "2018-12-02T21:34:33.000Z"   } } </pre> |

| Policy                               | Details   | Examples  |
|--------------------------------------|---|---|
|                                      | <p>T_DATE_TIME<br/>format. Here is an<br/>example: 2019-11-0<br/>1T22:13:4<br/>8.87+10:30:00 .</p>  |   |
| <p><b>ExpirationNotification</b></p> | <p>This policy initiates an event in Amazon EventBridge (EventBridge) that notifies you about the expiration. By using this policy, you can receive notifications before the expiration time is reached, in units of days or hours.</p>   | <pre>{   "Type": "ExpirationNotification",   "Version": "1.0",   "Attributes": {     "Before": "15",     "Unit": "Days"   } }</pre> |
| <p><b>NoChangeNotification</b></p>   | <p>This policy initiates an event in EventBridge if a parameter has <i>not</i> been modified for a specified period of time. This policy type is useful when, for example, a password needs to be changed within a period of time.</p> <p>This policy determines when to send a notification by reading the LastModifiedTime attribute of the parameter. If you change or edit a parameter, the system resets the notification time period based on the new value of LastModifiedTime .</p> | <pre>{   "Type": "NoChangeNotification",   "Version": "1.0",   "Attributes": {     "After": "20",     "Unit": "Days"   } }</pre>    |

You can assign multiple policies to a parameter. For example, you can assign `Expiration` and `ExpirationNotification` policies so that the system initiates an EventBridge event to notify you about the impending deletion of a parameter. You can assign a maximum of ten (10) policies to a parameter.

The following example shows the request syntax for a [PutParameter](#) API request that assigns four policies to a new `SecureString` parameter named `ProdDB3`.

```
{
  "Name": "ProdDB3",
  "Description": "Parameter with policies",
  "Value": "P@ssW*rd21",
  "Type": "SecureString",
  "Overwrite": "True",
  "Policies": [
    {
      "Type": "Expiration",
      "Version": "1.0",
      "Attributes": {
        "Timestamp": "2018-12-02T21:34:33.000Z"
      }
    },
    {
      "Type": "ExpirationNotification",
      "Version": "1.0",
      "Attributes": {
        "Before": "30",
        "Unit": "Days"
      }
    },
    {
      "Type": "ExpirationNotification",
      "Version": "1.0",
      "Attributes": {
        "Before": "15",
        "Unit": "Days"
      }
    },
    {
      "Type": "NoChangeNotification",
      "Version": "1.0",
      "Attributes": {
        "After": "20",

```

```
        "Unit": "Days"
      }
    }
  ]
}
```

## Adding policies to an existing parameter

This section includes information about how to add policies to an existing parameter by using the AWS Systems Manager console, the AWS Command Line Interface (AWS CLI), and AWS Tools for Windows PowerShell. For information about how to create a new parameter that includes policies, see [Creating Parameter Store parameters in Systems Manager](#).

### Topics

- [Adding policies to an existing parameter using the console](#)
- [Adding policies to an existing parameter using the AWS CLI](#)
- [Adding policies to an existing parameter \(Tools for Windows PowerShell\)](#)

## Adding policies to an existing parameter using the console

Use the following procedure to add policies to an existing parameter by using the Systems Manager console.

### To add policies to an existing parameter

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Parameter Store**.
3. Choose the option next to the parameter that you want to update to include policies, and then choose **Edit**.
4. Choose **Advanced**.
5. (Optional) In the **Parameter policies** section, choose **Enabled**. You can specify an expiration date and one or more notification policies for this parameter.
6. Choose **Save changes**.

### Important

- Parameter Store preserves policies on a parameter until you either overwrite the policies with new policies or remove the policies.
- To remove all policies from an existing parameter, edit the parameter and apply an empty policy by using brackets and curly braces, as follows: [{}]
- If you add a new policy to a parameter that already has policies, then Systems Manager overwrites the policies attached to the parameter. The existing policies are deleted. If you want to add a new policy to a parameter that already has one or more policies, copy and paste the original policies, type the new policy, and then save your changes.

## Adding policies to an existing parameter using the AWS CLI

Use the following procedure to add policies to an existing parameter by using the AWS CLI.

### To add policies to an existing parameter

1. Install and configure the AWS Command Line Interface (AWS CLI), if you haven't already.

For information, see [Installing or updating the latest version of the AWS CLI](#).

2. Run the following command to add policies to an existing parameter. Replace each *example resource placeholder* with your own information.

#### Linux & macOS

```
aws ssm put-parameter
  --name "parameter name" \
  --value 'parameter value' \
  --type parameter type \
  --overwrite \
  --policies "[policies-enclosed-in-brackets-and-curly-braces]"
```

#### Windows

```
aws ssm put-parameter
  --name "parameter name" ^
  --value 'parameter value' ^
  --type parameter type ^
```

```
--overwrite ^
--policies "[{policies-enclosed-in-brackets-and-curly-braces}]"
```

Here is an example that includes an expiration policy that deletes the parameter after 15 days. The example also includes a notification policy that generates an EventBridge event five (5) days before the parameter is deleted. Last, it includes a NoChangeNotification policy if no changes are made to this parameter after 60 days. The example uses an obfuscated name (313vat3131) for a password and an AWS Key Management Service AWS KMS key. For more information about AWS KMS keys, see [AWS Key Management Service Concepts](#) in the *AWS Key Management Service Developer Guide*.

## Linux & macOS

```
aws ssm put-parameter \
  --name "/Finance/Payroll/313vat3131" \
  --value "P@sSw)rd" \
  --type "SecureString" \
  --overwrite \
  --policies "[{"Type":"Expiration","Version":"1.0","Attributes":
{"Timestamp":"2020-05-13T00:00:00.000Z"}}, {"Type":"ExpirationNotification
","Version":"1.0","Attributes":{"Before":"5","Unit":"Days"}},
{"Type":"NoChangeNotification","Version":"1.0","Attributes":{"After
":"60","Unit":"Days"}}]"
```

## Windows

```
aws ssm put-parameter ^
  --name "/Finance/Payroll/313vat3131" ^
  --value "P@sSw)rd" ^
  --type "SecureString" ^
  --overwrite ^
  --policies "[{"Type":"Expiration","Version":"1.0","Attributes":
{"Timestamp":"2020-05-13T00:00:00.000Z"}}, {"Type":"ExpirationNotification
","Version":"1.0","Attributes":{"Before":"5","Unit":"Days"}},
{"Type":"NoChangeNotification","Version":"1.0","Attributes":{"After
":"60","Unit":"Days"}}]"
```

3. Run the following command to verify the details of the parameter. Replace *parameter name* with your own information.

## Linux & macOS

```
aws ssm describe-parameters \  
  --parameter-filters "Key=Name,Values=parameter name"
```

## Windows

```
aws ssm describe-parameters ^  
  --parameter-filters "Key=Name,Values=parameter name"
```

### Important

- Parameter Store retains policies for a parameter until you either overwrite the policies with new policies or remove the policies.
- To remove all policies from an existing parameter, edit the parameter and apply an empty policy of brackets and curly braces. Replace each *example resource placeholder* with your own information. For example:

## Linux & macOS

```
aws ssm put-parameter \  
  --name parameter name \  
  --type parameter type \  
  --value 'parameter value' \  
  --policies "[{}]"
```

## Windows

```
aws ssm put-parameter ^  
  --name parameter name ^  
  --type parameter type ^  
  --value 'parameter value' ^  
  --policies "[{}]"
```

- If you add a new policy to a parameter that already has policies, then Systems Manager overwrites the policies attached to the parameter. The existing policies are deleted. If you

want to add a new policy to a parameter that already has one or more policies, copy and paste the original policies, type the new policy, and then save your changes.

## Adding policies to an existing parameter (Tools for Windows PowerShell)

Use the following procedure to add policies to an existing parameter by using Tools for Windows PowerShell. Replace each *example resource placeholder* with your own information.

### To add policies to an existing parameter

1. Open Tools for Windows PowerShell and run the following command to specify your credentials. You must either have administrator permissions in Amazon Elastic Compute Cloud (Amazon EC2), or you must have been granted the appropriate permission in AWS Identity and Access Management (IAM).

```
Set-AWSCredentials `
  -AccessKey access-key-name `
  -SecretKey secret-key-name
```

2. Run the following command to set the Region for your PowerShell session. The example uses the US East (Ohio) Region (us-east-2).

```
Set-DefaultAWSRegion `
  -Region us-east-2
```

3. Run the following command to add policies to an existing parameter. Replace each *example resource placeholder* with your own information.

```
Write-SSMParameter `
  -Name "parameter name" `
  -Value "parameter value" `
  -Type "parameter type" `
  -Policies "[policies-enclosed-in-brackets-and-curly-braces]" `
  -Overwrite
```

Here is an example that includes an expiration policy that deletes the parameter at midnight (GMT) on May 13, 2020. The example also includes a notification policy that generates an EventBridge event five (5) days before the parameter is deleted. Last, it includes a

NoChangeNotification policy if no changes are made to this parameter after 60 days. The example uses an obfuscated name (313vat3131) for a password and an AWS managed key.

```
Write-SSMParameter `
  -Name "/Finance/Payroll/313vat3131" `
  -Value "P@sSwW)rd" `
  -Type "SecureString" `
  -Policies "[{"Type":"Expiration","Version":"1.0","Attributes":{"Timestamp":"2018-05-13T00:00:00.000Z"}}, {"Type":"ExpirationNotification","Version":"1.0","Attributes":{"Before":"5","Unit":"Days"}}, {"Type":"NoChangeNotification","Version":"1.0","Attributes":{"After":"60","Unit":"Days"}}]" `
  -Overwrite
```

4. Run the following command to verify the details of the parameter. Replace *parameter name* with your own information.

```
(Get-SSMParameterValue -Name "parameter name").Parameters
```

### Important

- Parameter Store preserves policies on a parameter until you either overwrite the policies with new policies or remove the policies.
- To remove all policies from an existing parameter, edit the parameter and apply an empty policy of brackets and curly braces. For example:

```
Write-SSMParameter `
  -Name "parameter name" `
  -Value "parameter value" `
  -Type "parameter type" `
  -Policies "[{}]"
```

- If you add a new policy to a parameter that already has policies, then Systems Manager overwrites the policies attached to the parameter. The existing policies are deleted. If you want to add a new policy to a parameter that already has one or more policies, copy and paste the original policies, type the new policy, and then save your changes.

## Working with parameter hierarchies in Parameter Store

Managing dozens or hundreds of parameters as a flat list is time consuming and prone to errors. It can also be difficult to identify the correct parameter for a task. This means you might accidentally use the wrong parameter, or you might create multiple parameters that use the same configuration data.

You can use parameter hierarchies to help you organize and manage parameters. A hierarchy is a parameter name that includes a path that you define by using forward slashes (/).

### Topics

- [Understanding parameter hierarchy through examples](#)
- [Querying parameters in a hierarchy](#)
- [Managing parameters using hierarchies using the AWS CLI](#)

### Understanding parameter hierarchy through examples

The following example uses three hierarchy levels in the name to identify the following:

```
/Environment/Type of computer/Application/Data
```

```
/Dev/DBServer/MySQL/db-string13
```

You can create a hierarchy with a maximum of 15 levels. We suggest that you create hierarchies that reflect an existing hierarchical structure in your environment, as shown in the following examples:

- Your [Continuous integration](#) and [Continuous delivery](#) environment (CI/CD workflows)

```
/Dev/DBServer/MySQL/db-string
```

```
/Staging/DBServer/MySQL/db-string
```

```
/Prod/DBServer/MySQL/db-string
```

- Your applications that use containers

```
/MyApp/.NET/Libraries/my-password
```

- Your business organization

```
/Finance/Accountants/UserList
```

```
/Finance/Analysts/UserList
```

```
/HR/Employees/EU/UserList
```

Parameter hierarchies standardize the way you create parameters and make it easier to manage parameters over time. A parameter hierarchy can also help you identify the correct parameter for a configuration task. This helps you to avoid creating multiple parameters with the same configuration data.

You can create a hierarchy that allows you to share parameters across different environments, as shown in the following examples that use passwords in development and staging environment.

```
/DevTest/MyApp/database/my-password
```

You could then create a unique password for your production environment, as shown in the following example:

```
/prod/MyApp/database/my-password
```

You aren't required to specify a parameter hierarchy. You can create parameters at level one. These are called *root* parameters. For backward compatibility, all parameters created in Parameter Store before hierarchies were released are root parameters. The system treats both of the following parameters as root parameters.

```
/parameter-name
```

```
parameter-name
```

## Querying parameters in a hierarchy

Another benefit of using hierarchies is the ability to query for all parameters within a hierarchy by using the [GetParametersByPath](#) API operation. For example, if you run the following command from the AWS Command Line Interface (AWS CLI), the system returns all parameters in the IIS level.

```
aws ssm get-parameters-by-path --path /Dev/Web/IIS
```

To view decrypted `SecureString` parameters in a hierarchy, you specify the path and the `--with-decryption` parameter, as shown in the following example.

```
aws ssm get-parameters-by-path --path /Prod/ERP/SAP --with-decryption
```

## Managing parameters using hierarchies using the AWS CLI

This procedure shows how to work with parameters and parameter hierarchies by using the AWS CLI.

### To manage parameters using hierarchies

1. Install and configure the AWS Command Line Interface (AWS CLI), if you haven't already.

For information, see [Installing or updating the latest version of the AWS CLI](#).

2. Run the following command to create a parameter that uses the `allowedPattern` parameter and the `String` parameter type. The allowed pattern in this example means the value for the parameter must be between 1 and 4 digits long.

#### Linux & macOS

```
aws ssm put-parameter \  
  --name "/MyService/Test/MaxConnections" \  
  --value 100 --allowed-pattern "\d{1,4}" \  
  --type String
```

#### Windows

```
aws ssm put-parameter ^  
  --name "/MyService/Test/MaxConnections" ^  
  --value 100 --allowed-pattern "\d{1,4}" ^  
  --type String
```

The command returns the version number of the parameter.

3. Run the following command to *attempt* to overwrite the parameter you just created with a new value.

#### Linux & macOS

```
aws ssm put-parameter \  
  --name "/MyService/Test/MaxConnections" \  
  --value 10,000 \  
  --type String
```

```
--type String \  
--overwrite
```

## Windows

```
aws ssm put-parameter ^  
  --name "/MyService/Test/MaxConnections" ^  
  --value 10,000 ^  
  --type String ^  
  --overwrite
```

The system returns the following error because the new value doesn't meet the requirements of the allowed pattern you specified in the previous step.

```
An error occurred (ParameterPatternMismatchException) when calling the PutParameter  
operation: Parameter value, cannot be validated against allowedPattern: \d{1,4}
```

4. Run the following command to create a SecureString parameter that uses an AWS managed key. The allowed pattern in this example means the user can specify any character, and the value must be between 8 and 20 characters.

## Linux & macOS

```
aws ssm put-parameter \  
  --name "/MyService/Test/my-password" \  
  --value "p#sW*rd33" \  
  --allowed-pattern ".{8,20}" \  
  --type SecureString
```

## Windows

```
aws ssm put-parameter ^  
  --name "/MyService/Test/my-password" ^  
  --value "p#sW*rd33" ^  
  --allowed-pattern ".{8,20}" ^  
  --type SecureString
```

5. Run the following commands to create more parameters that use the hierarchy structure from the previous step.

## Linux & macOS

```
aws ssm put-parameter \  
  --name "/MyService/Test/DBname" \  
  --value "SQLDevDb" \  
  --type String
```

```
aws ssm put-parameter \  
  --name "/MyService/Test/user" \  
  --value "SA" \  
  --type String
```

```
aws ssm put-parameter \  
  --name "/MyService/Test/userType" \  
  --value "SQLuser" \  
  --type String
```

## Windows

```
aws ssm put-parameter ^  
  --name "/MyService/Test/DBname" ^  
  --value "SQLDevDb" ^  
  --type String
```

```
aws ssm put-parameter ^  
  --name "/MyService/Test/user" ^  
  --value "SA" ^  
  --type String
```

```
aws ssm put-parameter ^  
  --name "/MyService/Test/userType" ^  
  --value "SQLuser" ^  
  --type String
```

6. Run the following command to get the value of two parameters.

## Linux & macOS

```
aws ssm get-parameters \  
  --names "/MyService/Test/DBname" "/MyService/Test/user"
```

```
--names "/MyService/Test/user" "/MyService/Test/userType"
```

## Windows

```
aws ssm get-parameters ^  
  --names "/MyService/Test/user" "/MyService/Test/userType"
```

7. Run the following command to query for all parameters within a single level.

## Linux & macOS

```
aws ssm get-parameters-by-path \  
  --path "/MyService/Test"
```

## Windows

```
aws ssm get-parameters-by-path ^  
  --path "/MyService/Test"
```

8. Run the following command to delete two parameters.

## Linux & macOS

```
aws ssm delete-parameters \  
  --names "/IADRegion/Dev/user" "/IADRegion/Dev/userType"
```

## Windows

```
aws ssm delete-parameters ^  
  --names "/IADRegion/Dev/user" "/IADRegion/Dev/userType"
```

## Preventing access to Parameter Store API operations

Using service-specific [conditions](#) supported by Systems Manager for AWS Identity and Access Management (IAM) policies, you can explicitly allow or deny access to Parameter Store API operations and content. By using these conditions, you can allow only certain IAM Entities (users and roles) in your organization to call certain API actions, or prevent certain IAM Entities from running them. This includes actions run through the Parameter Store console, the AWS Command Line Interface (AWS CLI), and SDKs.

Systems Manager currently supports three conditions that are specific to Parameter Store.

## Topics

- [Preventing changes to existing parameters using `ssm:Overwrite`](#)
- [Preventing creation or updates to parameters that use a parameter policy using `ssm:Policies`](#)
- [Preventing access to levels in a hierarchical parameter using `ssm:Recursive`](#)

## Preventing changes to existing parameters using `ssm:Overwrite`

Use the `ssm:Overwrite` condition to control whether IAM Entities can update existing parameters.

In the following sample policy, the "Allow" statement grants permission to create parameters by running the `PutParameter` API operation in the AWS account 123456789012 in the US East (Ohio) Region (`us-east-2`).

However, the "Deny" statement prevents Entities from changing values of *existing* parameters because the `Overwrite` option is explicitly denied for the `PutParameter` operation. Therefore, Entities that are assigned this policy can create parameters, but not make changes to existing parameters.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ssm:PutParameter"
      ],
      "Resource": "arn:aws:ssm:us-east-2:123456789012:parameter/*"
    },
    {
      "Effect": "Deny",
      "Action": [
        "ssm:PutParameter"
      ],
      "Condition": {
        "StringEquals": {
          "ssm:Overwrite": [
            "true"
          ]
        }
      }
    }
  ]
}
```

```

        }
      },
      "Resource": "arn:aws:ssm:us-east-2:123456789012:parameter/*"
    }
  ]
}

```

## Preventing creation or updates to parameters that use a parameter policy using `ssm:Policies`

User the `ssm:Policies` condition to control whether Entities can create parameters that include a parameter policy and update existing parameters that include a parameter policy.

In the following policy example, the "Allow" statement grants general permission to create and parameters, but the "Deny" statement prevents Entities from creating or updating parameters that include a parameter policy in the the AWS account 123456789012 in the US East (Ohio) Region (us-east-2). Entities can still create or update parameters that aren't assigned a parameter policy.

```

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ssm:PutParameter"
      ],
      "Resource": "arn:aws:ssm:us-east-2:123456789012:parameter/*"
    },
    {
      "Effect": "Deny",
      "Action": [
        "ssm:PutParameter"
      ],
      "Condition": {
        "StringEquals": {
          "ssm:Policies": [
            "true"
          ]
        }
      },
      "Resource": "arn:aws:ssm:us-east-2:123456789012:parameter/*"
    }
  ]
}

```

```
}
```

## Preventing access to levels in a hierarchical parameter using `ssm:Recursive`

Use the `ssm:Recursive` condition to control whether IAM Entities can view or reference levels in a hierarchical parameter. You can provide or restrict access to all parameters beyond a specific level of a hierarchy.

In the following example policy, the "Allow" statement provides access to Parameter Store operations on all parameters in the path `/Code/Departments/Finance/*` for the AWS account 123456789012 in the US East (Ohio) Region (`us-east-2`).

After this, the "Deny" statement prevents IAM Entities from viewing or retrieving parameter data at or below the level of `/Code/Departments/*`. Entities can still, however, still create or update parameters in that path. The example has been constructed to illustrate that recursively denying access below a certain level in a parameter hierarchy takes precedence over more permissive access in the same policy.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ssm:*"
      ],
      "Resource": "arn:aws:ssm:us-east-2:123456789012:parameter/*"
    },
    {
      "Effect": "Deny",
      "Action": [
        "ssm:GetParametersByPath"
      ],
      "Condition": {
        "StringEquals": {
          "ssm:Recursive": [
            "true"
          ]
        }
      },
      "Resource": "arn:aws:ssm:us-east-2:123456789012:parameter/Code/Departments/"
    }
  ]
}
```

```
    }  
  ]  
}
```

### Important

If a user has access to a path, then the user can access all levels of that path. For example, if a user has permission to access path `/a`, then the user can also access `/a/b`. This is true unless the user has explicitly been denied access in IAM for parameter `/b`, as illustrated above.

## Working with parameter labels in Parameter Store

A parameter label is a user-defined alias to help you manage different versions of a parameter. When you modify a parameter, AWS Systems Manager automatically saves a new version and increments the version number by one. A label can help you remember the purpose of a parameter version when there are multiple versions.

For example, let's say you have a parameter called `/MyApp/DB/ConnectionString`. The value of the parameter is a connection string to a MySQL server in a local database in a test environment. After you finish updating the application, you want the parameter to use a connection string for a production database. You change the value of `/MyApp/DB/ConnectionString`. Systems Manager automatically creates version two with the new connection string. To help you remember the purpose of each version, you attach a label to each parameter. For version one, you attach the label *Test* and for version two you attach the label *Production*.

You can move labels from one version of a parameter to another version. For example, if you create version 3 of the `/MyApp/DB/ConnectionString` parameter with a connection string for a new production database, then you can move the *Production* label from version 2 of the parameter to version 3 of the parameter.

Parameter labels are a lightweight alternative to parameter tags. Your organization might have strict guidelines for tags that must be applied to different AWS resources. In contrast, a label is simply a text association for a specific version of a parameter.

Similar to tags, you can query parameters by using labels. You can view a list of specific parameter versions that all use the same label if you query your parameter set by using the [GetParametersByPath](#) API operation, as described later in this section.

**Note**

If you run a command that specifies a version of a parameter that doesn't exist, the command fails. It doesn't fall back to the latest or default value of the parameter.

**Label requirements and restrictions**

Parameter labels have the following requirements and restrictions:

- A version of a parameter can have a maximum of 10 labels.
- You can't attach the same label to different versions of the same parameter. For example, if version 1 of the parameter has the label *Production*, then you can't attach *Production* to version 2.
- You can move a label from one version of a parameter to another.
- You can't create a label when you create a parameter. You must attach a label to a specific version of a parameter.
- If you no longer want to use a parameter label, then you can move it to a different version of a parameter or delete it.
- A label can have a maximum of 100 characters.
- Labels can contain letters (case sensitive), numbers, periods (.), hyphens (-), or underscores (\_).
- Labels can't begin with a number, "aws", or "ssm" (not case sensitive). If a label doesn't meet these requirements, then the label isn't attached to the parameter version and the system displays it in the list of `InvalidLabels`.

**Topics**

- [Working with parameter labels using the console](#)
- [Working with parameter labels using the AWS CLI](#)

**Working with parameter labels using the console**

This section describes how to perform the following tasks by using the Systems Manager console.

- [Creating a parameter label using the console](#)
- [Viewing labels attached to a parameter using the console](#)

- [Moving a parameter label using the console](#)
- [Deleting parameter labels using the console](#)

## Creating a parameter label using the console

The following procedure describes how to attach a label to a specific version of an *existing* parameter by using the Systems Manager console. You can't attach a label when you create a parameter.

### To attach a label to a parameter version

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Parameter Store**.
3. Choose the name of a parameter to open the details page for that parameter.
4. Choose the **History** tab.
5. Choose the parameter version for which you want to attach a label.
6. Choose **Manage labels**.
7. Choose **Add new label**.
8. In the text box, enter the label name. To add more labels, choose **Add new label**. You can attach a maximum of ten labels.
9. When you're finished, choose **Save changes**.

### Viewing labels attached to a parameter using the console

A parameter version can have a maximum of ten labels. The following procedure describes how to view all labels attached to a parameter version by using the Systems Manager console.

### To view labels attached to a parameter version

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Parameter Store**.
3. Choose the name of a parameter to open the details page for that parameter.
4. Choose the **History** tab.

5. Locate the parameter version for which you want to view all attached labels. The **Labels** column shows all labels attached to the parameter version.

### Moving a parameter label using the console

The following procedure describes how to move a parameter label to a different version of the same parameter by using the Systems Manager console.

#### To move a label to a different parameter version

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Parameter Store**.
3. Choose the name of a parameter to open the details page for that parameter.
4. Choose the **History** tab.
5. Choose the parameter version for which you want to move the label.
6. Choose **Manage labels**.
7. Choose **Add new label**.
8. In the text box, enter the label name.
9. When you're finished, choose **Save changes**.

### Deleting parameter labels using the console

The following procedure describes how to delete one or multiple parameter labels using the Systems Manager console.

#### To delete labels from a parameter

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Parameter Store**.
3. Choose the name of a parameter to open the details page for that parameter.
4. Choose the **History** tab.
5. Choose the parameter version for which you want to delete labels.
6. Choose **Manage labels**.

7. Choose **Remove**, next to each label you want to delete.
8. When you're finished, choose **Save changes**.
9. Confirm that your changes are correct, enter `Confirm` in the text box, and choose **Confirm**.

## Working with parameter labels using the AWS CLI

This section describes how to perform the following tasks by using the AWS Command Line Interface (AWS CLI).

- [Creating a new parameter label using the AWS CLI](#)
- [Viewing labels for a parameter using the AWS CLI](#)
- [Viewing a list of parameters that are assigned a label using the AWS CLI](#)
- [Moving a parameter label using the AWS CLI](#)
- [Deleting parameter labels using the AWS CLI](#)

## Creating a new parameter label using the AWS CLI

The following procedure describes how to attach a label to a specific version of an *existing* parameter by using the AWS CLI. You can't attach a label when you create a parameter.

### To create a parameter label

1. Install and configure the AWS Command Line Interface (AWS CLI), if you haven't already.

For information, see [Installing or updating the latest version of the AWS CLI](#).

2. Run the following command to view a list of parameters for which you have permission to attach a label.

#### Note

Parameters are only available in the AWS Region where they were created. If you don't see a parameter for which you want to attach a label, then verify your Region.

```
aws ssm describe-parameters
```

Note the name of a parameter for which you want to attach a label.

3. Run the following command to view all versions of the parameter.

```
aws ssm get-parameter-history --name "parameter-name"
```

Note the parameter version for which you want to attach a label.

4. Run the following command to retrieve information about a parameter by version number.

```
aws ssm get-parameters --names "parameter-name:version-number"
```

Here is an example.

```
aws ssm get-parameters --names "/Production/SQLConnectionString:3"
```

5. Run one of the following commands to attach a label to a version of a parameter. If you attach multiple labels, separate label names with a space.

#### Attach a label to the latest version of a parameter

```
aws ssm label-parameter-version --name parameter-name --labels label-name
```

#### Attach a label to a specific version of a parameter

```
aws ssm label-parameter-version --name parameter-name --parameter-version version-number --labels label-name
```

Here are some examples.

```
aws ssm label-parameter-version --name /config/endpoint --labels production east-region finance
```

```
aws ssm label-parameter-version --name /config/endpoint --parameter-version 3 --labels MySQL-test
```

#### Note

If the output shows the label you created in the `InvalidLabels` list, then the label doesn't meet the requirements described earlier in this topic. Review the requirements

and try again. If the `InvalidLabels` list is empty, then your label was successfully applied to the version of the parameter.

6. You can view the details of the parameter by using either a version number or a label name. Run the following command and specify the label you created in the previous step.

```
aws ssm get-parameter --name parameter-name:label-name --with-decryption
```

The command returns information like the following.

```
{
  "Parameter": {
    "Version": version-number,
    "Type": "parameter-type",
    "Name": "parameter-name",
    "Value": "parameter-value",
    "Selector": "::label-name"
  }
}
```

#### Note

*Selector* in the output is either the version number or the label that you specified in the Name input field.

## Viewing labels for a parameter using the AWS CLI

You can use the [GetParameterHistory](#) API operation to view the full history and all labels attached to a specified parameter. Or, you can use the [GetParametersByPath](#) API operation to view a list of all parameters that are assigned a specific label.

### To view labels for a parameter by using the `GetParameterHistory` API operation

1. Run the following command to view a list of parameters for which you can view labels.

**Note**

Parameters are only available in the Region where they were created. If you don't see a parameter for which you want to move a label, then verify your Region.

```
aws ssm describe-parameters
```

Note the name of the parameter you want to view the labels of.

2. Run the following command to view all versions of the parameter.

```
aws ssm get-parameter-history --name parameter-name --with-decryption
```

The system returns information like the following.

```
{
  "Parameters": [
    {
      "Name": "/Config/endpoint",
      "LastModifiedDate": 1528932105.382,
      "Labels": [
        "Deprecated"
      ],
      "Value": "MyTestService-June-Release.example.com",
      "Version": 1,
      "LastModifiedUser": "arn:aws:iam::123456789012:user/test",
      "Type": "String"
    },
    {
      "Name": "/Config/endpoint",
      "LastModifiedDate": 1528932111.222,
      "Labels": [
        "Current"
      ],
      "Value": "MyTestService-July-Release.example.com",
      "Version": 2,
      "LastModifiedUser": "arn:aws:iam::123456789012:user/test",
      "Type": "String"
    }
  ]
}
```

```
]
}
```

## Viewing a list of parameters that are assigned a label using the AWS CLI

You can use the [GetParametersByPath](#) API operation to view a list of all parameters in a path that are assigned a specific label.

Run the following command to view a list of parameters in a path that are assigned a specific label. Replace each *example resource placeholder* with your own information.

```
aws ssm get-parameters-by-path \
  --path parameter-path \
  --parameter-filters Key=Label,Values=label-name,Option=Equals \
  --max-results a-number \
  --with-decryption --recursive
```

The system returns information like the following. For this example, the user searched under the `/Config` path.

```
{
  "Parameters": [
    {
      "Version": 3,
      "Type": "SecureString",
      "Name": "/Config/DBpwd",
      "Value": "MyS@perGr&pass33"
    },
    {
      "Version": 2,
      "Type": "String",
      "Name": "/Config/DBusername",
      "Value": "TestUserDB"
    },
    {
      "Version": 2,
      "Type": "String",
      "Name": "/Config/endpoint",
      "Value": "MyTestService-July-Release.example.com"
    }
  ]
}
```

```
}
```

## Moving a parameter label using the AWS CLI

The following procedure describes how to move a parameter label to a different version of the same parameter.

### To move a parameter label

1. Run the following command to view all versions of the parameter. Replace *parameter name* with your own information.

```
aws ssm get-parameter-history \  
  --name "parameter name"
```

Note the parameter versions you want to move the label to and from.

2. Run the following command to assign an existing label to a different version of a parameter. Replace each *example resource placeholder* with your own information.

```
aws ssm label-parameter-version \  
  --name parameter name \  
  --parameter-version version number \  
  --labels name-of-existing-label
```

#### Note

If you want to move an existing label to the latest version of a parameter, then remove `--parameter-version` from the command.

## Deleting parameter labels using the AWS CLI

The following procedure describes how to delete parameter labels by using the AWS CLI.

### To delete a parameter label

1. Run the following command to view all versions of the parameter. Replace *parameter name* with your own information.

```
aws ssm get-parameter-history \  
  --name "parameter name"
```

```
--name "parameter name"
```

The system returns information like the following.

```
{
  "Parameters": [
    {
      "Name": "foo",
      "DataType": "text",
      "LastModifiedDate": 1607380761.11,
      "Labels": [
        "13",
        "12"
      ],
      "Value": "test",
      "Version": 1,
      "LastModifiedUser": "arn:aws:iam::123456789012:user/test",
      "Policies": [],
      "Tier": "Standard",
      "Type": "String"
    },
    {
      "Name": "foo",
      "DataType": "text",
      "LastModifiedDate": 1607380763.11,
      "Labels": [
        "11"
      ],
      "Value": "test",
      "Version": 2,
      "LastModifiedUser": "arn:aws:iam::123456789012:user/test",
      "Policies": [],
      "Tier": "Standard",
      "Type": "String"
    }
  ]
}
```

Note the parameter version for which you want to delete a label or labels.

2. Run the following command to delete the labels you choose from that parameter. Replace each *example resource placeholder* with your own information.

```
aws ssm unlabel-parameter-version \  
  --name parameter name \  
  --parameter-version version \  
  --labels label 1,label 2,label 3
```

The system returns information like the following.

```
{  
  "InvalidLabels": ["invalid"],  
  "DeletedLabels" : ["Prod"]  
}
```

## Working with parameter versions in Parameter Store

Each time you edit the value of a parameter, Parameter Store, a capability of AWS Systems Manager creates a new *version* of the parameter and retains the previous versions. When you initially create a parameter, Parameter Store assigns version 1 to that parameter. When you change the value of the parameter, Parameter Store automatically increments the version number by one. You can view the details, including the values, of all versions in a parameter's history.

You can also specify the version of a parameter to use in API commands and SSM documents; for example: `ssm:MyParameter:3`. You can specify a parameter name and a specific version number in API calls and SSM documents. If you don't specify a version number, the system automatically uses the latest version. If you specify the number for a version that doesn't exist, the system returns an error rather than falling back to the latest or default version of the parameter.

You can use parameter versions to see the number of times a parameter changed over a period of time. Parameter versions also provide a layer of protection if a parameter value is accidentally changed.

You can create and maintain up to 100 versions of a parameter. After you have created 100 versions of a parameter, each time you create a new version, the oldest version of the parameter is removed from history to make room for the new version.

An exception to this is when there are already 100 parameter versions in history, and a parameter label is assigned to the oldest version of a parameter. In this case, that version isn't removed from history, and the request to create a new parameter version fails. This safeguard is to prevent parameter versions with mission critical labels assigned to them from being deleted. To continue

creating new parameters, first move the label from the oldest version of the parameter to a newer one for use in your operations. For information about moving parameter labels, see [Moving a parameter label using the console](#) and [Moving a parameter label using the AWS CLI](#).

The following procedures show you how to edit a parameter and then verify that you created a new version. You can use the `get-parameter` and `get-parameters` commands to view parameter versions. For examples on using these commands, see [GetParameter](#) and [GetParameters](#) in the *AWS Systems Manager API Reference*

## Topics

- [Creating a new version of a parameter using the console](#)
- [Referencing a parameter version](#)

## Creating a new version of a parameter using the console

You can use the Systems Manager console to create a new version of a parameter and view the version history of a parameter.

### To create a new version of a parameter

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Parameter Store**.
3. Choose the name of a parameter that you created earlier. For information about creating a new parameter, see [Creating Parameter Store parameters in Systems Manager](#).
4. Choose **Edit**.
5. In the **Value** box, enter a new value, and then choose **Save changes**.
6. Choose the name of the parameter you just updated. On the **Overview** tab, verify that the version number incremented by 1, and verify the new value.
7. To view the history of all versions of a parameter, choose the **History** tab.

## Referencing a parameter version

You can reference specific parameter versions in commands, API calls, and SSM documents by using the following format: `ssm:parameter-name:version-number`.

In the following example, the Amazon Elastic Compute Cloud (Amazon EC2) `run-instances` command uses version 3 of the parameter `golden-ami`.

## Linux & macOS

```
aws ec2 run-instances \  
  --image-id resolve:ssm:/golden-ami:3 \  
  --count 1 \  
  --instance-type t2.micro \  
  --key-name my-key-pair \  
  --security-groups my-security-group
```

## Windows

```
aws ec2 run-instances ^  
  --image-id resolve:ssm:/golden-ami:3 ^  
  --count 1 ^  
  --instance-type t2.micro ^  
  --key-name my-key-pair ^  
  --security-groups my-security-group
```

### Note

Using `resolve` and a parameter value only works with the `--image-id` option and a parameter that contains an Amazon Machine Image (AMI) as its value. For more information, see [Using native parameter support in Parameter Store for Amazon Machine Image IDs](#).

Here is an example for specifying version 2 of a parameter named `MyRunCommandParameter` in an SSM document.

## YAML

```
---  
schemaVersion: '2.2'  
description: Run a shell script or specify the commands to run.  
parameters:  
  commands:
```

```

    type: String
    description: "(Required) Specify a shell script or a command to run."
    displayType: textarea
    default: "{{ssm:MyRunCommandParameter:2}}"
mainSteps:
- action: aws:runShellScript
  name: RunScript
  inputs:
    runCommand:
      - "{{commands}}"

```

## JSON

```

{
  "schemaVersion": "2.2",
  "description": "Run a shell script or specify the commands to run.",
  "parameters": {
    "commands": {
      "type": "String",
      "description": "(Required) Specify a shell script or a command to run.",
      "displayType": "textarea",
      "default": "{{ssm:MyRunCommandParameter:2}}"
    }
  },
  "mainSteps": [
    {
      "action": "aws:runShellScript",
      "name": "RunScript",
      "inputs": {
        "runCommand": [
          "{{commands}}"
        ]
      }
    }
  ]
}

```

## Working with shared parameters in Parameter Store

Sharing advanced parameters simplifies configuration data management in a multi-account environment. You can centrally store and manage your parameters and share them with other AWS accounts that need to reference them.

Parameter Store integrates with AWS Resource Access Manager (AWS RAM) to enable advanced parameter sharing. AWS RAM is a service that enables you to share resources with other AWS accounts or through AWS Organizations.

With AWS RAM, you share resources that you own by creating a resource share. A resource share specifies the resources to share, permissions to grant, and the consumers with whom to share. Consumers can include:

- Specific AWS accounts inside or outside of its organization in AWS Organizations
- An organizational unit inside its organization in AWS Organizations
- Its entire organization in AWS Organizations

For more information about AWS RAM, see the [AWS RAM User Guide](#).

This topic explains how to share parameters that you own, and how to use parameters that are shared with you.

## Contents

- [Prerequisites for sharing parameters](#)
- [Sharing a parameter](#)
- [Stop sharing a shared parameter](#)
- [Identifying shared parameters](#)
- [Accessing shared parameters](#)
- [Permissions sets for sharing parameters](#)
- [Maximum throughput for shared parameters](#)
- [Pricing for shared parameters](#)
- [Cross-account access for closed AWS accounts](#)

## Prerequisites for sharing parameters

The following prerequisites must be met before you can share parameters from your account:

- To share a parameter, you must own it in your AWS account. You can't share a parameter that has been shared with you.
- To share a parameter, it must be in the advanced parameter tier. For information about parameter tiers, see [Managing parameter tiers](#). For information about changing an existing

standard parameter to an advanced parameter, see [Changing a standard parameter to an advanced parameter](#).

- To share a SecureString parameter, it must be encrypted with a customer managed key, and you must share the key separately through AWS Key Management Service. AWS managed keys cannot be shared. Parameters encrypted with the default AWS managed key can be updated to use a customer managed key instead. For AWS KMS key definitions, see [AWS KMS concepts](#) in the *AWS Key Management Service Developer Guide*.
- To share a parameter with your organization or an organizational unit in AWS Organizations, you must enable sharing with AWS Organizations. For more information, see [Enable Sharing with AWS Organizations](#) in the *AWS RAM User Guide*.

## Sharing a parameter

To share a parameter, you must add it to a resource share. A resource share is an AWS RAM resource that lets you share your resources across AWS accounts. A resource share specifies the resources to share, and the consumers with whom they are shared.

When you share a parameter that you own with other AWS accounts, you can choose from two AWS managed permissions to grant the consumers. For more information, see [Permissions sets for sharing parameters](#).

If you are part of an organization in AWS Organizations and sharing within your organization is enabled, you can grant consumers in your organization access from the AWS RAM console to the shared parameter. Otherwise, consumers receive an invitation to join the resource share and are granted access to the shared parameter after accepting the invitation.

You can share a parameter that you own using the AWS RAM console, or the AWS CLI.

### Note

While you can share a parameter using the Systems Manager [PutResourcePolicy](#) API operation, we recommend using AWS Resource Access Manager (AWS RAM) instead. This is because using `PutResourcePolicy` requires the extra step of promoting the parameter to a standard Resource Share using the AWS RAM [PromoteResourceShareCreatedFromPolicy](#) API operation. Otherwise, the parameter won't be returned by the Systems Manager [DescribeParameters](#) API operation using the `--shared` option.

## To share a parameter that you own using the AWS RAM console

See [Creating a resource share in AWS RAM](#) in the *AWS RAM User Guide*.

Make the following selections as you complete the procedure:

- In the Step 1 page, for **Resources**, select **Parameter Store Advanced Parameter**, and then select the box of each parameter in the advanced parameter tier that you want to share.
- In the Step 2 page, for **Managed permissions**, choose the permission to grant consumers, as described in [Permissions sets for sharing parameters](#) later in this topic.

Choose other options based on your parameter sharing objectives.

## To share a parameter that you own using the AWS CLI

Use the [create-resource-share](#) command to add parameters to a new resource share.

Use the [associate-resource-share](#) command to add parameters to an existing resource share.

The following example creates a new resource share to share parameters with consumers in an organization and in an individual account.

```
aws ram create-resource-share \  
  --name "MyParameter" \  
  --resource-arns "arn:aws:ssm:us-east-2:123456789012:parameter/MyParameter" \  
  --principals "arn:aws:organizations::123456789012:ou/o-63bEXAMPLE/ou-46xi-rEXAMPLE" \  
  "987654321098"
```

## Stop sharing a shared parameter

When you stop sharing a shared parameter, the consumer account can no longer access the parameter.

To stop sharing a parameter that you own, you must remove it from the resource share. You can do this using the Systems Manager console, AWS RAM console, or the AWS CLI.

## To stop sharing a parameter that you own using the AWS RAM console

See [Update a resource share in AWS RAM](#) in the *AWS RAM User Guide*.

## To stop sharing a parameter that you own using the AWS CLI

Use the [disassociate-resource-share](#) command.

## Identifying shared parameters

Owners and consumers can identify shared parameters using the AWS CLI.

### To identify shared parameters using the AWS CLI

To identify shared parameters using the AWS CLI, you can choose from the Systems Manager [describe-parameters](#) command and the AWS RAM [list-resources](#) command.

When you use the `--shared` option with `describe-parameters`, the command returns the parameters that are shared with you.

The following is an example:

```
aws ssm describe-parameters --shared
```

## Accessing shared parameters

Consumers can access shared parameters using the AWS command line tools, and AWS SDKs. For consumer accounts, parameters shared with that account aren't included in the **My parameters** page.

### CLI Example: Accessing shared parameter details using the AWS CLI

To access shared parameter details using the AWS CLI, you can use the [get-parameter](#) or [get-parameters](#) commands. You must specify the full parameter ARN as the `--name` in order to retrieve the parameter from another account.

The following is an example.

```
aws ssm get-parameter \  
  --name arn:aws:ssm:us-east-2:123456789012:parameter/MySharedParameter
```

## Supported and unsupported integrations for shared parameters

Currently, you can use shared parameters in the following integration scenarios:

- AWS CloudFormation [template parameters](#)
- The [AWS Parameters and Secrets Lambda extension](#)
- [Amazon Elastic Compute Cloud \(EC2\) launch templates](#)
- Values for ImageID with the [EC2 RunInstances command](#) to create instances from an Amazon Machine Image (AMI)

- [Retrieving parameter values in runbooks](#) for Automation, a capability of Systems Manager

The following scenarios and integrated services do not currently support the use of shared parameters:

- [Parameters in commands](#) in Run Command, a capability of Systems Manager
- AWS CloudFormation [dynamic references](#)
- The [values of environment variables](#) in AWS CodeBuild
- The [values of environment variables](#) in AWS App Runner
- The [value of a secret](#) in Amazon Elastic Container Service

### Permissions sets for sharing parameters

Consumer accounts receive read-only access to the parameters you share with them. The consumer can't update or delete the parameter. The consumer can't share the parameter with a third account.

When you create a resource share in AWS Resource Access Manager for sharing your parameters, you can choose from two AWS managed permission sets to grant this read-only access:

#### **AWSRAMDefaultPermissionSSMParameterReadOnly**

Allowed actions: `DescribeParameters`, `GetParameter`, `GetParameters`

#### **AWSRAMPermissionSSMParameterReadOnlyWithHistory**

Allowed actions: `DescribeParameters`, `GetParameter`, `GetParameters`, `GetParameterHistory`

When you follow the steps in [Creating a resource share in AWS RAM](#) in the *AWS RAM User Guide*, choose `Parameter Store Advanced Parameters` as the resource type and either of these managed permissions, depending on whether you want users to view parameter history or not.

### Maximum throughput for shared parameters

Systems Manager limits the maximum throughput (transactions per second) for the [GetParameter](#) and [GetParameters](#) operations. Throughput is enforced at the individual account level. Therefore, each account that consumes a shared parameter can use its maximum allowed throughput without being affected by other accounts. For more information about maximum throughput for parameters, see the following topics:

- [Increasing Parameter Store throughput](#)
- [Systems Manager Service quotas](#) in the *Amazon Web Services General Reference*.

## Pricing for shared parameters

Cross-account sharing is only available in the advanced parameter tier. For advanced parameters, charges are incurred at the current price for the *storage* and *API usage* for each advanced parameter. The owning account is charged for storage of the advanced parameter. Any consuming account that makes an API call to a shared advanced parameter is charged for the parameter usage.

For example, if Account A creates an advanced parameter, `MyAdvancedParameter`, that account is charged USD 0.05 per month to store the parameter.

Account A then shares `MyAdvancedParameter` with Account B and Account C. During a month, the three accounts make calls to `MyAdvancedParameter`. The following table illustrates the charges they would incur for the number of calls each makes.

### Note

The charges in the following table are for illustration only. To verify current pricing, see [AWS Systems Manager Pricing for Parameter Store](#).

| Account                       | Number of calls | Charges   |
|-------------------------------|-----------------|---|
| Account A (owning account)    | 10,000 calls    | <ul style="list-style-type: none"> <li>• One month advanced parameter storage: USD 0.05</li> <li>• 10,000 calls to <code>MyAdvancedParameter</code> : USD 0.05</li> <li>• <b>Total: USD 0.10</b></li> </ul> |
| Account B (consuming account) | 20,000 calls    | <ul style="list-style-type: none"> <li>• 20,000 calls to <code>MyAdvancedParameter</code> : USD 0.10</li> <li>• <b>Total: USD 0.10</b></li> </ul>   |

| Account                       | Number of calls | Charges  |
|-------------------------------|-----------------|--|
| Account C (consuming account) | 30,000 calls    | <ul style="list-style-type: none"> <li>30,000 calls to MyAdvancedParameter : USD 0.15</li> <li><b>Total: USD 0.15</b></li> </ul> |

## Cross-account access for closed AWS accounts

If the AWS account that owns a shared parameter is closed, all consuming accounts lose access to the shared parameter. If the owning account is reopened within 90 days after the account is closed, consuming accounts regain access to the previously shared parameters. For more information about reopening an account during the Post-Closure Period, see [Accessing your AWS account after you close it](#) in the *AWS Account Management Reference Guide*.

## Working with parameters in Parameter Store using Run Command commands

You can work with parameters in Run Command, a capability of AWS Systems Manager. For more information, see [AWS Systems Manager Run Command](#).

## Running a String parameter using the console

The following procedure walks you through the process of running a command that uses a String parameter.

### To run a String parameter using Parameter Store

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Run Command**.
3. Choose **Run command**.
4. In the **Command document** list, choose `AWS-RunPowerShellScript (Windows)` or `AWS-RunShellScript (Linux)`.
5. For **Command parameters**, enter `echo {{ssm:parameter-name}}`. For example: `echo {{ssm:/Test/helloWorld}}`.
6. In the **Targets** section, choose the managed nodes on which you want to run this operation by specifying tags, selecting instances or edge devices manually, or specifying a resource group.

**Tip**

If a managed node you expect to see isn't listed, see [Troubleshooting managed node availability](#) for troubleshooting tips.

**7. For Other parameters:**

- For **Comment**, enter information about this command.
- For **Timeout (seconds)**, specify the number of seconds for the system to wait before failing the overall command execution.

**8. For Rate control:**

- For **Concurrency**, specify either a number or a percentage of managed nodes on which to run the command at the same time.

**Note**

If you selected targets by specifying tags applied to managed nodes or by specifying AWS resource groups, and you aren't certain how many managed nodes are targeted, then restrict the number of targets that can run the document at the same time by specifying a percentage.

- For **Error threshold**, specify when to stop running the command on other managed nodes after it fails on either a number or a percentage of nodes. For example, if you specify three errors, then Systems Manager stops sending the command when the fourth error is received. Managed nodes still processing the command might also send errors.
9. (Optional) For **Output options**, to save the command output to a file, select the **Write command output to an S3 bucket** box. Enter the bucket and prefix (folder) names in the boxes.

**Note**

The S3 permissions that grant the ability to write the data to an S3 bucket are those of the instance profile (for EC2 instances) or IAM service role (hybrid-activated machines) assigned to the instance, not those of the IAM user performing this task. For more information, see [Configure instance permissions required for Systems Manager](#) or [Create an IAM service role for a hybrid environment](#). In addition, if the specified S3

bucket is in a different AWS account, make sure that the instance profile or IAM service role associated with the managed node has the necessary permissions to write to that bucket.

10. In the **SNS notifications** section, if you want notifications sent about the status of the command execution, select the **Enable SNS notifications** check box.

For more information about configuring Amazon SNS notifications for Run Command, see [Monitoring Systems Manager status changes using Amazon SNS notifications](#).

11. Choose **Run**.
12. In the **Command ID** page, in the **Targets and outputs** area, select the button next to the ID of a node where you ran the command, and then choose **View output**. Verify that the output of the command is the value you provided for the parameter, such as **This is my first parameter**.

## Running a parameter using the AWS CLI

### Example 1: Simple command

The following example command includes a Systems Manager parameter named DNS-IP. The value of this parameter is simply the IP address of a node. This example uses an AWS Command Line Interface (AWS CLI) command to echo the parameter value.

#### Linux & macOS

```
aws ssm send-command \  
  --document-name "AWS-RunShellScript" \  
  --document-version "1" \  
  --targets "Key=instanceids,Values=i-02573cafcfEXAMPLE" \  
  --parameters "commands='echo {{ssm:DNS-IP}}'" \  
  --timeout-seconds 600 \  
  --max-concurrency "50" \  
  --max-errors "0" \  
  --region us-east-2
```

#### Windows

```
aws ssm send-command ^  
  --document-name "AWS-RunPowerShellScript" ^
```

```
--document-version "1" ^
--targets "Key=instanceids,Values=i-02573cafcfEXAMPLE" ^
--parameters "commands='echo {{ssm:DNS-IP}}'" ^
--timeout-seconds 600 ^
--max-concurrency "50" ^
--max-errors "0" ^
--region us-east-2
```

The command returns information like the following.

```
{
  "Command": {
    "CommandId": "c70a4671-8098-42da-b885-89716EXAMPLE",
    "DocumentName": "AWS-RunShellScript",
    "DocumentVersion": "1",
    "Comment": "",
    "ExpiresAfter": "2023-12-26T15:19:17.771000-05:00",
    "Parameters": {
      "commands": [
        "echo {{ssm:DNS-IP}}"
      ]
    },
    "InstanceIds": [],
    "Targets": [
      {
        "Key": "instanceids",
        "Values": [
          "i-02573cafcfEXAMPLE"
        ]
      }
    ]
  },
  "RequestedDateTime": "2023-12-26T14:09:17.771000-05:00",
  "Status": "Pending",
  "StatusDetails": "Pending",
  "OutputS3Region": "us-east-2",
  "OutputS3BucketName": "",
  "OutputS3KeyPrefix": "",
  "MaxConcurrency": "50",
  "MaxErrors": "0",
  "TargetCount": 0,
  "CompletedCount": 0,
  "ErrorCount": 0,
}
```

```

    "DeliveryTimedOutCount": 0,
    "ServiceRole": "",
    "NotificationConfig": {
      "NotificationArn": "",
      "NotificationEvents": [],
      "NotificationType": ""
    },
    "CloudWatchOutputConfig": {
      "CloudWatchLogGroupName": "",
      "CloudWatchOutputEnabled": false
    },
    "TimeoutSeconds": 600,
    "AlarmConfiguration": {
      "IgnorePollAlarmFailure": false,
      "Alarms": []
    },
    "TriggeredAlarms": []
  }
}

```

After a command execution completes, you can view more information about it using the following commands:

- [get-command-invocation](#) – View detailed information about the command execution.
- [list-command-invocations](#) – View the command execution status on a specific managed node.
- [list-commands](#) – View the command execution status across managed nodes.

## Example 2: Decrypt a SecureString parameter value

The next example command uses a SecureString parameter named **SecurePassword**. The command used in the `parameters` field retrieves and decrypts the value of the SecureString parameter, and then resets the local administrator password without having to pass the password in clear text.

### Linux

```

aws ssm send-command \
  --document-name "AWS-RunShellScript" \
  --document-version "1" \
  --targets "Key=instanceids,Values=i-02573cafcfEXAMPLE" \

```

```

--parameters '{"commands":["secure=$(aws ssm get-parameters --names
SecurePassword --with-decryption --query Parameters[0].Value --output text --region
us-east-2)","echo $secure | passwd myuser --stdin"]}' \
--timeout-seconds 600 \
--max-concurrency "50" \
--max-errors "0" \
--region us-east-2

```

## Windows

```

aws ssm send-command ^
--document-name "AWS-RunPowerShellScript" ^
--document-version "1" ^
--targets "Key=instanceids,Values=i-02573cafcfEXAMPLE" ^
--parameters "commands=['$secure = (Get-SSMParameterValue -Names
SecurePassword -WithDecryption $True).Parameters[0].Value','net user administrator
$secure']" ^
--timeout-seconds 600 ^
--max-concurrency "50" ^
--max-errors "0" ^
--region us-east-2

```

### Example 3: Reference a parameter in an SSM document

You can also reference Systems Manager parameters in the *Parameters* section of an SSM document, as shown in the following example.

```

{
  "schemaVersion":"2.0",
  "description":"Sample version 2.0 document v2",
  "parameters":{
    "commands" : {
      "type": "StringList",
      "default": ["{{ssm:parameter-name}}"]
    }
  },
  "mainSteps":[
    {
      "action":"aws:runShellScript",
      "name":"runShellScript",
      "inputs":{
        "runCommand": "{{commands}}"
      }
    }
  ]
}

```

```

    }
  }
]
}

```

Don't confuse the similar syntax for *local parameters* used in the `runtimeConfig` section of SSM documents with Parameter Store parameters. A local parameter isn't the same as a Systems Manager parameter. You can distinguish local parameters from Systems Manager parameters by the absence of the `ssm:` prefix.

```

"runtimeConfig":{
  "aws:runShellScript":{
    "properties":[
      {
        "id":"0.aws:runShellScript",
        "runCommand":"{{ commands }}",
        "workingDirectory":"{{ workingDirectory }}",
        "timeoutSeconds":"{{ executionTimeout }}"
      }
    ]
  }
}

```

### Note

SSM documents don't support references to `SecureString` parameters. This means that to use `SecureString` parameters with, for example, Run Command, you have to retrieve the parameter value before passing it to Run Command, as shown in the following examples.

#### Linux & macOS

```
value=$(aws ssm get-parameters --names parameter-name --with-decryption)
```

```
aws ssm send-command \
  --name AWS-JoinDomain \
  --parameters password=$value \
  --instance-id instance-id
```

#### Windows

```
aws ssm send-command ^
  --name AWS-JoinDomain ^
  --parameters password=$value ^
```

```
--instance-id instance-id
```

## Powershell

```
$secure = (Get-SSMParameterValue -Names parameter-name -WithDecryption  
$True).Parameters[0].Value | ConvertTo-SecureString -AsPlainText -Force
```

```
$cred = New-Object System.Management.Automation.PSCredential -  
argumentlist user-name,$secure
```

## Using native parameter support in Parameter Store for Amazon Machine Image IDs

When you create a String parameter, you can specify the *data type* as `aws:ec2:image` to ensure that the parameter value you enter is a valid Amazon Machine Image (AMI) ID format.

Support for AMI ID formats allows you to avoid updating all your scripts and templates with a new ID each time the AMI that you want to use in your processes changes. You can create a parameter with the data type `aws:ec2:image`, and for its value, enter the ID of an AMI. This is the AMI you want to create new instances from. You then reference this parameter in your templates, commands, and scripts.

For example, you can specify the parameter that contains your preferred AMI ID when you run the Amazon Elastic Compute Cloud (Amazon EC2) `run-instances` command.

### Note

The user who runs this command must have AWS Identity and Access Management (IAM) permissions that include the `ssm:GetParameters` API operation in order for the parameter value to be validated. Otherwise, the parameter creation process fails.

## Linux & macOS

```
aws ec2 run-instances \  
  --image-id resolve:ssm:/golden-ami \  
  --count 1 \  
  --instance-type t2.micro \  
  --key-name my-key-pair \  
  --
```

```
--security-groups my-security-group
```

## Windows

```
aws ec2 run-instances ^
  --image-id resolve:ssm:/golden-ami ^
  --count 1 ^
  --instance-type t2.micro ^
  --key-name my-key-pair ^
  --security-groups my-security-group
```

You can also choose your preferred AMI when you create an instance using the Amazon EC2 console. For more information, see [Using a Systems Manager parameter to find an AMI](#) in the *Amazon EC2 User Guide*.

When it's time to use a different AMI in your instance creation workflow, you need only update the parameter with the new AMI value, and Parameter Store again validates that you have entered an ID in the proper format.

### Granting permissions to create a parameter of `aws:ec2:image` data type

Using AWS Identity and Access Management (IAM) policies, you can provide or restrict user access to Parameter Store API operations and content.

To create an `aws:ec2:image` data type parameter, the user must have both `ssm:PutParameter` and `ec2:DescribeImages` permissions.

The following example policy grants users permission to call the `PutParameter` API operation for `aws:ec2:image`. This means that the user can add a parameter of data type `aws:ec2:image` to the system.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "ssm:PutParameter",
      "Resource": "*"
    },
    {
```

```
        "Effect": "Allow",
        "Action": "ec2:DescribeImages",
        "Resource": "*"
    }
]
}
```

## How AMI format validation works

When you specify `aws:ec2:image` as the data type for a parameter, Systems Manager doesn't create the parameter immediately. It instead performs an asynchronous validation operation to ensure that the parameter value meets the formatting requirements for an AMI ID, and that the specified AMI is available in your AWS account.

A parameter version number might be generated before the validation operation is complete. The operation might not be complete even if a parameter version number is generated.

To monitor whether your parameters are created successfully, we recommend using Amazon EventBridge to send you notifications about your create and update parameter operations. These notifications report whether a parameter operation was successful or not. If an operation fails, the notification includes an error message that indicates the reason for the failure.

```
{
  "version": "0",
  "id": "eed4a719-0fa4-6a49-80d8-8ac65EXAMPLE",
  "detail-type": "Parameter Store Change",
  "source": "aws.ssm",
  "account": "111122223333",
  "time": "2020-05-26T22:04:42Z",
  "region": "us-east-2",
  "resources": [
    "arn:aws:ssm:us-east-2:111122223333:parameter/golden-ami"
  ],
  "detail": {
    "exception": "Unable to Describe Resource",
    "dataType": "aws:ec2:image",
    "name": "golden-ami",
    "type": "String",
    "operation": "Create"
  }
}
```

For information about subscribing to Parameter Store events in EventBridge, see [Setting up notifications or triggering actions based on Parameter Store events](#).

## Deleting parameters from Parameter Store

This topic describes how to delete parameters that you have created in Parameter Store, a capability of AWS Systems Manager.

### Warning

Deleting a parameter removes all versions of it. Once deleted, the parameter and its versions can't be restored.

## To delete a parameter using the console

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Parameter Store**.
3. On the **My parameters** tab, select the check box next to each parameter to delete.
4. Choose **Delete**.
5. On the confirmation dialog, choose **Delete parameters**.

## To delete a parameter using the AWS CLI

- Run the following command:

```
aws ssm delete-parameter --name "my-parameter"
```

Replace *my-parameter* with the name of your parameter to be deleted.

For information about all options available for use with the `delete-parameter` command, see [delete-parameter](#) in the *AWS Systems Manager section of the AWS CLI Command Reference*.

## Working with public parameters in Parameter Store

Some AWS services publish information about common artifacts as AWS Systems Manager *public* parameters. For example, the Amazon Elastic Compute Cloud (Amazon EC2) service publishes information about Amazon Machine Images (AMIs) as public parameters.

### Topics in this guide

- [Discovering public parameters in Parameter Store](#)
- [Calling AMI public parameters in Parameter Store](#)
- [Calling the ECS optimized AMI public parameter in Parameter Store](#)
- [Calling the EKS optimized AMI public parameter in Parameter Store](#)
- [Calling public parameters for AWS services, Regions, endpoints, Availability Zones, local zones, and Wavelength Zones in Parameter Store](#)

### Related AWS blog posts

- [Query for the latest Amazon Linux AMI IDs using AWS Systems Manager Parameter Store](#)
- [Query for the Latest Windows AMI Using AWS Systems Manager Parameter Store](#)

### Discovering public parameters in Parameter Store

You can search for public parameters using the Parameter Store console or the AWS Command Line Interface.

A public parameter name begins with `aws/service/list`. The next part of the name corresponds to the service that owns that parameter.

The following is a list of some services which provide public parameters:

- `ami-amazon-linux-latest`
- `ami-windows-latest`
- `ec2-macos`
- `appmesh`
- `aws-for-fluent-bit`

- `bottlerocket`
- `canonical`
- `cloud9`
- `datasync`
- `debian`
- `ecs`
- `eks`
- `freebsd`
- `global-infrastructure`
- `marketplace`
- `storagegateway`

Not all public parameters are published to every AWS Region.

### Finding public parameters using the Parameter Store console

You must have at least one parameter in your AWS account and AWS Region before you can search for public parameters using the console.

#### To find public parameters using the console

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Parameter Store**.
3. Choose the **Public parameters** tab.
4. Choose the **Select a service** dropdown. Choose the service whose parameters you want to use.
5. (Optional) Filter the parameters owned by the service you selected by entering more information into the search bar.
6. Choose the public parameter you want to use.

### Finding public parameters using the AWS CLI

Use `describe-parameters` for discovery of public parameters.

Use `get-parameters-by-path` to get the actual path for a service listed under `/aws/service/list`. To get the service's path, remove `/list` from the path. For example, `/aws/service/list/ecs` becomes `/aws/service/ecs`.

To retrieve a list of public parameters owned by different services in Parameter Store, run the following command.

```
aws ssm get-parameters-by-path --path /aws/service/list
```

The command returns information like the following. This example has been truncated for space.

```
{
  "Parameters": [
    {
      "Name": "/aws/service/list/ami-al-latest",
      "Type": "String",
      "Value": "/aws/service/ami-al-latest/",
      "Version": 1,
      "LastModifiedDate": "2021-01-29T10:25:10.902000-08:00",
      "ARN": "arn:aws:ssm:us-east-2::parameter/aws/service/list/ami-al-latest",
      "DataType": "text"
    },
    {
      "Name": "/aws/service/list/ami-windows-latest",
      "Type": "String",
      "Value": "/aws/service/ami-windows-latest/",
      "Version": 1,
      "LastModifiedDate": "2021-01-29T10:25:12.567000-08:00",
      "ARN": "arn:aws:ssm:us-east-2::parameter/aws/service/list/ami-windows-
latest",
      "DataType": "text"
    },
    {
      "Name": "/aws/service/list/aws-storage-gateway-latest",
      "Type": "String",
      "Value": "/aws/service/aws-storage-gateway-latest/",
      "Version": 1,
      "LastModifiedDate": "2021-01-29T10:25:09.903000-08:00",
      "ARN": "arn:aws:ssm:us-east-2::parameter/aws/service/list/aws-storage-
gateway-latest",
      "DataType": "text"
    },
    {
```

```

        "Name": "/aws/service/list/global-infrastructure",
        "Type": "String",
        "Value": "/aws/service/global-infrastructure/",
        "Version": 1,
        "LastModifiedDate": "2021-01-29T10:25:11.901000-08:00",
        "ARN": "arn:aws:ssm:us-east-2::parameter/aws/service/list/global-
infrastructure",
        "DataType": "text"
    }
]
}

```

If you want to view parameters owned by a specific service, choose the service from the list that was produced after running the earlier command. Then, make a `get-parameters-by-path` call using the name of your desired service.

For example, `/aws/service/global-infrastructure`. The path might be one-level (only calls parameters that match the exact values given) or recursive (contains elements in the path beyond what you have given).

### Note

The `/aws/service/global-infrastructure` path is not supported for queries in all Regions. For information, see [Calling public parameters for AWS services, Regions, endpoints, Availability Zones, local zones, and Wavelength Zones in Parameter Store](#).

If no results are returned for the service you specify, add the `--recursive` flag and run the command again.

```
aws ssm get-parameters-by-path --path /aws/service/global-infrastructure
```

This returns all parameters owned by `global-infrastructure`. The following is an example.

```

{
  "Parameters": [
    {
      "Name": "/aws/service/global-infrastructure/current-region",
      "Type": "String",
      "LastModifiedDate": "2019-06-21T05:15:34.252000-07:00",
      "Version": 1,

```

```

    "Tier": "Standard",
    "Policies": [],
    "DataType": "text"
  },
  {
    "Name": "/aws/service/global-infrastructure/version",
    "Type": "String",
    "LastModifiedDate": "2019-02-04T06:59:32.875000-08:00",
    "Version": 1,
    "Tier": "Standard",
    "Policies": [],
    "DataType": "text"
  }
]
}

```

You can also view parameters owned by a specific service by using the `Option:BeginsWith` filter.

```
aws ssm describe-parameters --parameter-filters "Key=Name, Option=BeginsWith, Values=/aws/service/ami-amazon-linux-latest"
```

The command returns information like the following. This example output has been truncated for space.

```

{
  "Parameters": [
    {
      "Name": "/aws/service/ami-amazon-linux-latest/amzn-ami-hvm-x86_64-eb",
      "Type": "String",
      "LastModifiedDate": "2021-01-26T13:39:40.686000-08:00",
      "Version": 25,
      "Tier": "Standard",
      "Policies": [],
      "DataType": "text"
    },
    {
      "Name": "/aws/service/ami-amazon-linux-latest/amzn-ami-hvm-x86_64-gp2",
      "Type": "String",
      "LastModifiedDate": "2021-01-26T13:39:40.807000-08:00",
      "Version": 25,
      "Tier": "Standard",
      "Policies": [],
      "DataType": "text"
    }
  ]
}

```

```
    },  
    {  
      "Name": "/aws/service/ami-amazon-linux-latest/amzn-ami-hvm-x86_64-s3",  
      "Type": "String",  
      "LastModifiedDate": "2021-01-26T13:39:40.920000-08:00",  
      "Version": 25,  
      "Tier": "Standard",  
      "Policies": [],  
      "DataType": "text"  
    }  
  ]  
}
```

### Note

The returned parameters might be different when you use `Option=BeginsWith` because it uses a different search pattern.

## Calling AMI public parameters in Parameter Store

Amazon Elastic Compute Cloud (Amazon EC2) Amazon Machine Image (AMI) public parameters are available for Amazon Linux 1, Amazon Linux 2, Amazon Linux 2023 (AL2023), macOS, and Windows Server from the following paths:

- Amazon Linux 1, Amazon Linux 2, and Amazon Linux 2023: `/aws/service/ami-amazon-linux-latest`
- macOS: `/aws/service/ec2-macos`
- Windows Server: `/aws/service/ami-windows-latest`

## Calling AMI public parameters for Amazon Linux 1, Amazon Linux 2, and Amazon Linux 2023

You can view a list of all Amazon Linux 1, Amazon Linux 2, and Amazon Linux 2023 (AL2023) AMIs in the current AWS Region by using the following command in the AWS Command Line Interface (AWS CLI).

### Linux & macOS

```
aws ssm get-parameters-by-path \
```

```
--path /aws/service/ami-amazon-linux-latest \  
--query 'Parameters[].Name'
```

## Windows

```
aws ssm get-parameters-by-path ^  
--path /aws/service/ami-amazon-linux-latest ^  
--query Parameters[].Name
```

The command returns information like the following.

```
[  
  "/aws/service/ami-amazon-linux-latest/al2023-ami-kernel-6.1-arm64",  
  "/aws/service/ami-amazon-linux-latest/al2023-ami-kernel-6.1-x86_64",  
  "/aws/service/ami-amazon-linux-latest/al2023-ami-minimal-kernel-6.1-arm64",  
  "/aws/service/ami-amazon-linux-latest/al2023-ami-minimal-kernel-6.1-x86_64",  
  "/aws/service/ami-amazon-linux-latest/al2023-ami-minimal-kernel-default-arm64",  
  "/aws/service/ami-amazon-linux-latest/amzn-ami-hvm-x86_64-gp2",  
  "/aws/service/ami-amazon-linux-latest/amzn-ami-hvm-x86_64-s3",  
  "/aws/service/ami-amazon-linux-latest/amzn2-ami-hvm-x86_64-efs",  
  "/aws/service/ami-amazon-linux-latest/amzn2-ami-hvm-x86_64-gp2",  
  "/aws/service/ami-amazon-linux-latest/amzn2-ami-kernel-5.10-hvm-x86_64-efs",  
  "/aws/service/ami-amazon-linux-latest/al2023-ami-kernel-default-arm64",  
  "/aws/service/ami-amazon-linux-latest/al2023-ami-kernel-default-x86_64",  
  "/aws/service/ami-amazon-linux-latest/al2023-ami-minimal-kernel-default-x86_64",  
  "/aws/service/ami-amazon-linux-latest/amzn-ami-hvm-x86_64-efs",  
  "/aws/service/ami-amazon-linux-latest/amzn-ami-minimal-hvm-x86_64-efs",  
  "/aws/service/ami-amazon-linux-latest/amzn-ami-minimal-hvm-x86_64-s3",  
  "/aws/service/ami-amazon-linux-latest/amzn2-ami-hvm-arm64-gp2",  
  "/aws/service/ami-amazon-linux-latest/amzn2-ami-kernel-5.10-hvm-arm64-gp2",  
  "/aws/service/ami-amazon-linux-latest/amzn2-ami-kernel-5.10-hvm-x86_64-gp2",  
  "/aws/service/ami-amazon-linux-latest/amzn2-ami-minimal-hvm-arm64-efs",  
  "/aws/service/ami-amazon-linux-latest/amzn2-ami-minimal-hvm-x86_64-efs"  
]
```

You can view details about these AMIs, including the AMI IDs and Amazon Resource Names (ARNs), by using the following command.

## Linux & macOS

```
aws ssm get-parameters-by-path \  

```

```
--path "/aws/service/ami-amazon-linux-latest" \  
--region region
```

## Windows

```
aws ssm get-parameters-by-path ^  
--path "/aws/service/ami-amazon-linux-latest" ^  
--region region
```

*region* represents the identifier for an AWS Region supported by AWS Systems Manager, such as `us-east-2` for the US East (Ohio) Region. For a list of supported *region* values, see the **Region** column in [Systems Manager service endpoints](#) in the *Amazon Web Services General Reference*.

The command returns information like the following. This example output has been truncated for space.

```
{  
  "Parameters": [  
    {  
      "Name": "/aws/service/ami-amazon-linux-latest/al2023-ami-kernel-6.1-arm64",  
      "Type": "String",  
      "Value": "ami-0b1b8b24a6c8e5d8b",  
      "Version": 69,  
      "LastModifiedDate": "2024-03-13T14:05:09.583000-04:00",  
      "ARN": "arn:aws:ssm:us-east-2::parameter/aws/service/ami-amazon-linux-latest/al2023-ami-kernel-6.1-arm64",  
      "DataType": "text"  
    },  
    {  
      "Name": "/aws/service/ami-amazon-linux-latest/al2023-ami-kernel-6.1-x86_64",  
      "Type": "String",  
      "Value": "ami-0e0bf53f6def86294",  
      "Version": 69,  
      "LastModifiedDate": "2024-03-13T14:05:09.890000-04:00",  
      "ARN": "arn:aws:ssm:us-east-2::parameter/aws/service/ami-amazon-linux-latest/al2023-ami-kernel-6.1-x86_64",  
      "DataType": "text"  
    },  
    {  
      "Name": "/aws/service/ami-amazon-linux-latest/al2023-ami-minimal-kernel-6.1-arm64",  
      "Type": "String",  
      "Value": "ami-0c0b0b0b0b0b0b0b",  
      "Version": 69,  
      "LastModifiedDate": "2024-03-13T14:05:09.890000-04:00",  
      "ARN": "arn:aws:ssm:us-east-2::parameter/aws/service/ami-amazon-linux-latest/al2023-ami-minimal-kernel-6.1-arm64",  
      "DataType": "text"  
    }  
  ]  
}
```

```

        "Type": "String",
        "Value": "ami-09951bb66f9e5b5a5",
        "Version": 69,
        "LastModifiedDate": "2024-03-13T14:05:10.197000-04:00",
        "ARN": "arn:aws:ssm:us-east-2::parameter/aws/service/ami-amazon-linux-
latest/al2023-ami-minimal-kernel-6.1-arm64",
        "DataType": "text"
    }
]
}

```

You can view details of a specific AMI by using the [GetParameters](#) API operation with the full AMI name, including the path. Here is an example command.

### Linux & macOS

```

aws ssm get-parameters \
  --names /aws/service/ami-amazon-linux-latest/al2023-ami-kernel-6.1-arm64 \
  --region us-east-2

```

### Windows

```

aws ssm get-parameters ^
  --names /aws/service/ami-amazon-linux-latest/al2023-ami-kernel-6.1-arm64 ^
  --region us-east-2

```

The command returns the following information.

```

{
  "Parameters": [
    {
      "Name": "/aws/service/ami-amazon-linux-latest/al2023-ami-kernel-6.1-arm64",
      "Type": "String",
      "Value": "ami-0b1b8b24a6c8e5d8b",
      "Version": 69,
      "LastModifiedDate": "2024-03-13T14:05:09.583000-04:00",
      "ARN": "arn:aws:ssm:us-east-2::parameter/aws/service/ami-amazon-linux-
latest/al2023-ami-kernel-6.1-arm64",
      "DataType": "text"
    }
  ],
}

```

```
"InvalidParameters": []
}
```

## Calling AMI public parameters for macOS

You can view a list of all macOS AMIs in the current AWS Region by using the following command in the AWS CLI.

### Linux & macOS

```
aws ssm get-parameters-by-path \
  --path /aws/service/ec2-macos\
  --query 'Parameters[].Name'
```

### Windows

```
aws ssm get-parameters-by-path ^
  --path /aws/service/ec2-macos ^
  --query Parameters[].Name
```

The command returns information like the following.

```
[
  "/aws/service/ec2-macos/sonoma/x86_64_mac/latest/image_id",
  "/aws/service/ec2-macos/ventura/x86_64_mac/latest/image_id",
  "/aws/service/ec2-macos/monterey/x86_64_mac/latest/image_id",
  "/aws/service/ec2-macos/sonoma/arm64_mac/latest/image_id",
  "/aws/service/ec2-macos/ventura/arm64_mac/latest/image_id",
  "/aws/service/ec2-macos/monterey/arm64_mac/latest/image_id"
]
```

You can view details about these AMIs, including the AMI IDs and Amazon Resource Names (ARNs), by using the following command.

### Linux & macOS

```
aws ssm get-parameters-by-path \
  --path "/aws/service/ec2-macos" \
  --region region
```

## Windows

```
aws ssm get-parameters-by-path ^
  --path "/aws/service/ec2-macos" ^
  --region region
```

*region* represents the identifier for an AWS Region supported by AWS Systems Manager, such as `us-east-2` for the US East (Ohio) Region. For a list of supported *region* values, see the **Region** column in [Systems Manager service endpoints](#) in the *Amazon Web Services General Reference*.

The command returns information like the following. This example output has been truncated for space.

```
{
  "Parameters": [
    ...sample results pending...
  ]
}
```

You can view details of a specific AMI by using the [GetParameters](#) API operation with the full AMI name, including the path. Here is an example command.

## Linux & macOS

```
aws ssm get-parameters \
  --names /aws/service/ec2-macos/...pending... \
  --region us-east-2
```

## Windows

```
aws ssm get-parameters ^
  --names /aws/service/ec2-macos/...pending... ^
  --region us-east-2
```

The command returns the following information.

```
{
  "Parameters": [
```

```

    ...sample results pending...
  ],
  "InvalidParameters": []
}

```

## Calling AMI public parameters for Windows Server

You can view a list of all Windows Server AMIs in the current AWS Region by using the following command in the AWS CLI.

### Linux & macOS

```

aws ssm get-parameters-by-path \
  --path /aws/service/ami-windows-latest \
  --query 'Parameters[].Name'

```

### Windows

```

aws ssm get-parameters-by-path ^
  --path /aws/service/ami-windows-latest ^
  --query Parameters[].Name

```

The command returns information like the following. This example output has been truncated for space.

```

[
  "/aws/service/ami-windows-latest/EC2LaunchV2-Windows_Server-2016-English-Full-Base",
  "/aws/service/ami-windows-latest/Windows_Server-2016-English-Full-SQL_2014_SP3_Enterprise",
  "/aws/service/ami-windows-latest/Windows_Server-2016-German-Full-Base",
  "/aws/service/ami-windows-latest/Windows_Server-2016-Japanese-Full-SQL_2016_SP3_Standard",
  "/aws/service/ami-windows-latest/Windows_Server-2016-Japanese-Full-SQL_2017_Web",
  "/aws/service/ami-windows-latest/Windows_Server-2019-English-Core-EKS_Optimized-1.25",
  "/aws/service/ami-windows-latest/Windows_Server-2019-Italian-Full-Base",
  "/aws/service/ami-windows-latest/Windows_Server-2022-Japanese-Full-SQL_2019_Enterprise",
  "/aws/service/ami-windows-latest/Windows_Server-2022-Portuguese_Brazil-Full-Base",
  "/aws/service/ami-windows-latest/amzn2-ami-hvm-2.0.20191217.0-x86_64-gp2-mono",

```

```

"/aws/service/ami-windows-latest/amzn2-x86_64-SQL_2019_Express",
"/aws/service/ami-windows-latest/EC2LaunchV2-Windows_Server-2016-English-Core-
Base",
"/aws/service/ami-windows-latest/Windows_Server-2016-English-Full-
SQL_2019_Enterprise",
"/aws/service/ami-windows-latest/Windows_Server-2016-English-Full-
SQL_2019_Standard",
"/aws/service/ami-windows-latest/Windows_Server-2016-Portuguese_Portugal-Full-
Base",
"/aws/service/ami-windows-latest/Windows_Server-2019-English-Core-
EKS_Optimized-1.24",
"/aws/service/ami-windows-latest/Windows_Server-2019-English-Deep-Learning",
"/aws/service/ami-windows-latest/Windows_Server-2019-English-Full-SQL_2017_Web",
"/aws/service/ami-windows-latest/Windows_Server-2019-Hungarian-Full-Base
]

```

You can view details about these AMIs, including the AMI IDs and Amazon Resource Names (ARNs), by using the following command.

## Linux & macOS

```

aws ssm get-parameters-by-path \
  --path "/aws/service/ami-windows-latest" \
  --region region

```

## Windows

```

aws ssm get-parameters-by-path ^
  --path "/aws/service/ami-windows-latest" ^
  --region region

```

*region* represents the identifier for an AWS Region supported by AWS Systems Manager, such as `us-east-2` for the US East (Ohio) Region. For a list of supported *region* values, see the **Region** column in [Systems Manager service endpoints](#) in the *Amazon Web Services General Reference*.

The command returns information like the following. This example output has been truncated for space.

```
{
  "Parameters": [
    {
      "Name": "/aws/service/ami-windows-latest/EC2LaunchV2-Windows_Server-2016-English-Full-Base",
      "Type": "String",
      "Value": "ami-0a30b2e65863e2d16",
      "Version": 36,
      "LastModifiedDate": "2024-03-15T15:58:37.976000-04:00",
      "ARN": "arn:aws:ssm:us-east-2::parameter/aws/service/ami-windows-latest/EC2LaunchV2-Windows_Server-2016-English-Full-Base",
      "DataType": "text"
    },
    {
      "Name": "/aws/service/ami-windows-latest/Windows_Server-2016-English-Full-SQL_2014_SP3_Enterprise",
      "Type": "String",
      "Value": "ami-001f20c053dd120ce",
      "Version": 69,
      "LastModifiedDate": "2024-03-15T15:53:58.905000-04:00",
      "ARN": "arn:aws:ssm:us-east-2::parameter/aws/service/ami-windows-latest/Windows_Server-2016-English-Full-SQL_2014_SP3_Enterprise",
      "DataType": "text"
    },
    {
      "Name": "/aws/service/ami-windows-latest/Windows_Server-2016-German-Full-Base",
      "Type": "String",
      "Value": "ami-063be4935453e94e9",
      "Version": 102,
      "LastModifiedDate": "2024-03-15T15:51:12.003000-04:00",
      "ARN": "arn:aws:ssm:us-east-2::parameter/aws/service/ami-windows-latest/Windows_Server-2016-German-Full-Base",
      "DataType": "text"
    }
  ]
}
```

```
}
```

You can view details of a specific AMI by using the [GetParameters](#) API operation with the full AMI name, including the path. Here is an example command.

## Linux & macOS

```
aws ssm get-parameters \  
  --names /aws/service/ami-windows-latest/EC2LaunchV2-Windows_Server-2016-English-  
Full-Base \  
  --region us-east-2
```

## Windows

```
aws ssm get-parameters ^  
  --names /aws/service/ami-windows-latest/EC2LaunchV2-Windows_Server-2016-English-  
Full-Base ^  
  --region us-east-2
```

The command returns the following information.

```
{  
  "Parameters": [  
    {  
      "Name": "/aws/service/ami-windows-latest/EC2LaunchV2-Windows_Server-2016-  
English-Full-Base",  
      "Type": "String",  
      "Value": "ami-0a30b2e65863e2d16",  
      "Version": 36,  
      "LastModifiedDate": "2024-03-15T15:58:37.976000-04:00",  
      "ARN": "arn:aws:ssm:us-east-2::parameter/aws/service/ami-windows-latest/  
EC2LaunchV2-Windows_Server-2016-English-Full-Base",  
      "DataType": "text"  
    }  
  ],  
  "InvalidParameters": []  
}
```

## Calling the ECS optimized AMI public parameter in Parameter Store

The Amazon Elastic Container Service (Amazon ECS) service publishes the name of the latest Amazon ECS optimized Amazon Machine Images (AMIs) as public parameters. Users are encouraged to use this AMI when creating a new Amazon Elastic Compute Cloud (Amazon EC2) cluster for Amazon ECS because the optimized AMIs include bug fixes and feature updates.

Use the following command to view the name of the latest Amazon ECS optimized AMI for Amazon Linux 2. To see commands for other operating systems, see [Retrieving Amazon ECS-Optimized AMI metadata](#) in the *Amazon Elastic Container Service Developer Guide*.

### Linux & macOS

```
aws ssm get-parameters \  
  --names /aws/service/ecs/optimized-ami/amazon-linux-2/recommended
```

### Windows

```
aws ssm get-parameters ^  
  --names /aws/service/ecs/optimized-ami/amazon-linux-2/recommended
```

The command returns information like the following.

```
{  
  "Parameters": [  
    {  
      "Name": "/aws/service/ecs/optimized-ami/amazon-linux-2/recommended",  
      "Type": "String",  
      "Value": "{\"schema_version\":1,\"image_name\":\"amzn2-ami-ecs-hvm-2.0.20210929-x86_64-ebs\",\"image_id\":\"ami-0c38a2329ed4dae9a\",\"os\":\"Amazon Linux 2\",\"ecs_runtime_version\":\"Docker version 20.10.7\",\"ecs_agent_version\":\"1.55.4\"}",  
      "Version": 73,  
      "LastModifiedDate": "2021-10-06T16:35:10.004000-07:00",  
      "ARN": "arn:aws:ssm:us-east-2::parameter/aws/service/ecs/optimized-ami/amazon-linux-2/recommended",  
      "DataType": "text"  
    }  
  ],  
  "InvalidParameters": []  
}
```

## Calling the EKS optimized AMI public parameter in Parameter Store

The Amazon Elastic Kubernetes Service (Amazon EKS) service publishes the name of the latest Amazon EKS optimized Amazon Machine Image (AMI) as a public parameter. We encourage you to use this AMI when adding nodes to an Amazon EKS cluster, as new releases include Kubernetes patches and security updates. Previously, to guarantee you were using the latest AMI meant checking the Amazon EKS documentation and manually updating any deployment templates or resources with the new AMI ID.

Use the following command to view the name of the latest Amazon EKS optimized AMI for Amazon Linux 2.

### Linux & macOS

```
aws ssm get-parameters \  
  --names /aws/service/eks/optimized-ami/1.14/amazon-linux-2/recommended
```

### Windows

```
aws ssm get-parameters ^  
  --names /aws/service/eks/optimized-ami/1.14/amazon-linux-2/recommended
```

The command returns information like the following.

```
{  
  "Parameters": [  
    {  
      "Name": "/aws/service/eks/optimized-ami/1.14/amazon-linux-2/recommended",  
      "Type": "String",  
      "Value": "{\"schema_version\": \"2\", \"image_id\": \"ami-08984d8491de17ca0\",  
\"image_name\": \"amazon-eks-node-1.14-v20201007\", \"release_version\":  
\"1.14.9-20201007\"}",  
      "Version": 24,  
      "LastModifiedDate": "2020-11-17T10:16:09.971000-08:00",  
      "ARN": "arn:aws:ssm:us-east-2::parameter/aws/service/eks/optimized-  
ami/1.14/amazon-linux-2/recommended",  
      "DataType": "text"  
    }  
  ],  
  "InvalidParameters": []  
}
```

```
}
```

## Calling public parameters for AWS services, Regions, endpoints, Availability Zones, local zones, and Wavelength Zones in Parameter Store

You can call the AWS Region, service, endpoint, Availability, and Wavelength Zones of public parameters by using the following path.

```
/aws/service/global-infrastructure
```

### Note

Currently, the path `/aws/service/global-infrastructure` is supported for queries in the following AWS Regions only:

- US East (N. Virginia) (us-east-1)
- US East (Ohio) (us-east-2)
- US West (N. California) (us-west-1)
- US West (Oregon) (us-west-2)
- Asia Pacific (Hong Kong) (ap-east-1)
- Asia Pacific (Mumbai) (ap-south-1)
- Asia Pacific (Seoul) (ap-northeast-2)
- Asia Pacific (Singapore) (ap-southeast-1)
- Asia Pacific (Sydney) (ap-southeast-2)
- Asia Pacific (Tokyo) (ap-northeast-1)
- Canada (Central) (ca-central-1)
- Europe (Frankfurt) (eu-central-1)
- Europe (Ireland) (eu-west-1)
- Europe (London) (eu-west-2)
- Europe (Paris) (eu-west-3)
- Europe (Stockholm) (eu-north-1)
- South America (São Paulo) (sa-east-1)

If you are working in a different [commercial Region](#), you can specify a supported Region in your query to view results. For example, if you are working in the Canada West (Calgary) (ca-west-1) Region, you could specify Canada (Central) (ca-central-1) in your query:

```
aws ssm get-parameters-by-path \  
  --path /aws/service/global-infrastructure/regions \  
  --region ca-central-1
```

## View active AWS Regions

You can view a list of all active AWS Regions by using the following command in the AWS Command Line Interface (AWS CLI).

### Linux & macOS

```
aws ssm get-parameters-by-path \  
  --path /aws/service/global-infrastructure/regions \  
  --query 'Parameters[].Name'
```

### Windows

```
aws ssm get-parameters-by-path ^  
  --path /aws/service/global-infrastructure/regions ^  
  --query Parameters[].Name
```

The command returns information like the following.

```
[  
  "/aws/service/global-infrastructure/regions/af-south-1",  
  "/aws/service/global-infrastructure/regions/ap-east-1",  
  "/aws/service/global-infrastructure/regions/ap-northeast-3",  
  "/aws/service/global-infrastructure/regions/ap-south-2",  
  "/aws/service/global-infrastructure/regions/ca-central-1",  
  "/aws/service/global-infrastructure/regions/eu-central-2",  
  "/aws/service/global-infrastructure/regions/eu-west-2",  
  "/aws/service/global-infrastructure/regions/eu-west-3",  
  "/aws/service/global-infrastructure/regions/us-east-1",
```

```
"/aws/service/global-infrastructure/regions/us-gov-west-1",
"/aws/service/global-infrastructure/regions/ap-northeast-2",
"/aws/service/global-infrastructure/regions/ap-southeast-1",
"/aws/service/global-infrastructure/regions/ap-southeast-2",
"/aws/service/global-infrastructure/regions/ap-southeast-3",
"/aws/service/global-infrastructure/regions/cn-north-1",
"/aws/service/global-infrastructure/regions/cn-northwest-1",
"/aws/service/global-infrastructure/regions/eu-south-1",
"/aws/service/global-infrastructure/regions/eu-south-2",
"/aws/service/global-infrastructure/regions/us-east-2",
"/aws/service/global-infrastructure/regions/us-west-1",
"/aws/service/global-infrastructure/regions/ap-northeast-1",
"/aws/service/global-infrastructure/regions/ap-south-1",
"/aws/service/global-infrastructure/regions/ap-southeast-4",
"/aws/service/global-infrastructure/regions/ca-west-1",
"/aws/service/global-infrastructure/regions/eu-central-1",
"/aws/service/global-infrastructure/regions/il-central-1",
"/aws/service/global-infrastructure/regions/me-central-1",
"/aws/service/global-infrastructure/regions/me-south-1",
"/aws/service/global-infrastructure/regions/sa-east-1",
"/aws/service/global-infrastructure/regions/us-gov-east-1",
"/aws/service/global-infrastructure/regions/eu-north-1",
"/aws/service/global-infrastructure/regions/eu-west-1",
"/aws/service/global-infrastructure/regions/us-west-2"
]
```

## View available AWS services

You can view a complete list of all available AWS services and sort them into alphabetical order by using the following command. This example output has been truncated for space.

### Linux & macOS

```
aws ssm get-parameters-by-path \
  --path /aws/service/global-infrastructure/services \
  --query 'Parameters[].Name | sort(@)'
```

### Windows

```
aws ssm get-parameters-by-path ^
  --path /aws/service/global-infrastructure/services ^
  --query "Parameters[].Name | sort(@)"
```

The command returns information like the following. This example has been truncated for space.

```
[
  "/aws/service/global-infrastructure/services/accessanalyzer",
  "/aws/service/global-infrastructure/services/account",
  "/aws/service/global-infrastructure/services/acm",
  "/aws/service/global-infrastructure/services/acm-pca",
  "/aws/service/global-infrastructure/services/ahl",
  "/aws/service/global-infrastructure/services/aiq",
  "/aws/service/global-infrastructure/services/amazonlocationsservice",
  "/aws/service/global-infrastructure/services/amplify",
  "/aws/service/global-infrastructure/services/amplifybackend",
  "/aws/service/global-infrastructure/services/apigateway",
  "/aws/service/global-infrastructure/services/apigatewaymanagementapi",
  "/aws/service/global-infrastructure/services/apigatewayv2",
  "/aws/service/global-infrastructure/services/appconfig",
  "/aws/service/global-infrastructure/services/appconfigdata",
  "/aws/service/global-infrastructure/services/appflow",
  "/aws/service/global-infrastructure/services/appintegrations",
  "/aws/service/global-infrastructure/services/application-autoscaling",
  "/aws/service/global-infrastructure/services/application-insights",
  "/aws/service/global-infrastructure/services/applicationcostprofiler",
  "/aws/service/global-infrastructure/services/appmesh",
  "/aws/service/global-infrastructure/services/apprunner",
  "/aws/service/global-infrastructure/services/appstream",
  "/aws/service/global-infrastructure/services/appsync",
  "/aws/service/global-infrastructure/services/aps",
  "/aws/service/global-infrastructure/services/arc-zonal-shift",
  "/aws/service/global-infrastructure/services/artifact",
  "/aws/service/global-infrastructure/services/athena",
  "/aws/service/global-infrastructure/services/auditmanager",
  "/aws/service/global-infrastructure/services/augmentedairuntime",
  "/aws/service/global-infrastructure/services/aurora",
  "/aws/service/global-infrastructure/services/autoscaling",
  "/aws/service/global-infrastructure/services/aws-appfabric",
  "/aws/service/global-infrastructure/services/awshealthdashboard",
```

## View supported Regions for an AWS service

You can view a list of AWS Regions where a service is available. This example uses AWS Systems Manager (ssm).

## Linux & macOS

```
aws ssm get-parameters-by-path \  
  --path /aws/service/global-infrastructure/services/ssm/regions \  
  --query 'Parameters[].Value'
```

## Windows

```
aws ssm get-parameters-by-path ^  
  --path /aws/service/global-infrastructure/services/ssm/regions ^  
  --query Parameters[].Value
```

The command returns information like the following.

```
[  
  "ap-south-1",  
  "eu-central-1",  
  "eu-central-2",  
  "eu-west-1",  
  "eu-west-2",  
  "eu-west-3",  
  "il-central-1",  
  "me-south-1",  
  "us-east-2",  
  "us-gov-west-1",  
  "af-south-1",  
  "ap-northeast-3",  
  "ap-southeast-1",  
  "ap-southeast-4",  
  "ca-central-1",  
  "ca-west-1",  
  "cn-north-1",  
  "eu-north-1",  
  "eu-south-2",  
  "us-west-1",  
  "ap-east-1",  
  "ap-northeast-1",  
  "ap-northeast-2",  
  "ap-southeast-2",  
  "ap-southeast-3",  
  "cn-northwest-1",  
  "eu-south-1",
```

```
"me-central-1",  
"us-gov-east-1",  
"us-west-2",  
"ap-south-2",  
"sa-east-1",  
"us-east-1"  
]
```

## View the Regional endpoint for a service

You can view a Regional endpoint for a service by using the following command. This command queries the US East (Ohio) (us-east-2) Region.

### Linux & macOS

```
aws ssm get-parameter \  
  --name /aws/service/global-infrastructure/regions/us-east-2/services/ssm/  
endpoint \  
  --query 'Parameter.Value'
```

### Windows

```
aws ssm get-parameter ^  
  --name /aws/service/global-infrastructure/regions/us-east-2/services/ssm/  
endpoint ^  
  --query Parameter.Value
```

The command returns information like the following.

```
"ssm.us-east-2.amazonaws.com"
```

## View complete Availability Zone details

You can view Availability Zones by using the following command.

### Linux & macOS

```
aws ssm get-parameters-by-path \  
  --path /aws/service/global-infrastructure/availability-zones/
```

## Windows

```
aws ssm get-parameters-by-path ^  
  --path /aws/service/global-infrastructure/availability-zones/
```

The command returns information like the following. This example has been truncated for space.

```
{  
  "Parameters": [  
    {  
      "Name": "/aws/service/global-infrastructure/availability-zones/afs1-az3",  
      "Type": "String",  
      "Value": "afs1-az3",  
      "Version": 1,  
      "LastModifiedDate": "2020-04-21T12:05:35.375000-04:00",  
      "ARN": "arn:aws:ssm:us-east-2::parameter/aws/service/global-infrastructure/  
availability-zones/afs1-az3",  
      "DataType": "text"  
    },  
    {  
      "Name": "/aws/service/global-infrastructure/availability-zones/aps1-az2",  
      "Type": "String",  
      "Value": "aps1-az2",  
      "Version": 1,  
      "LastModifiedDate": "2020-04-03T16:13:57.351000-04:00",  
      "ARN": "arn:aws:ssm:us-east-2::parameter/aws/service/global-infrastructure/  
availability-zones/aps1-az2",  
      "DataType": "text"  
    },  
    {  
      "Name": "/aws/service/global-infrastructure/availability-zones/apse3-az1",  
      "Type": "String",  
      "Value": "apse3-az1",  
      "Version": 1,  
      "LastModifiedDate": "2021-12-13T08:51:38.983000-05:00",  
      "ARN": "arn:aws:ssm:us-east-2::parameter/aws/service/global-infrastructure/  
availability-zones/apse3-az1",  
      "DataType": "text"  
    }  
  ]  
}
```

## View Availability Zone names only

You can view the names of Availability Zones only by using the following command.

### Linux & macOS

```
aws ssm get-parameters-by-path \  
  --path /aws/service/global-infrastructure/availability-zones \  
  --query 'Parameters[].Name | sort(@)'
```

### Windows

```
aws ssm get-parameters-by-path ^  
  --path /aws/service/global-infrastructure/availability-zones ^  
  --query "Parameters[].Name | sort(@)"
```

The command returns information like the following. This example has been truncated for space.

```
[  
  "/aws/service/global-infrastructure/availability-zones/afs1-az1",  
  "/aws/service/global-infrastructure/availability-zones/afs1-az2",  
  "/aws/service/global-infrastructure/availability-zones/afs1-az3",  
  "/aws/service/global-infrastructure/availability-zones/ape1-az1",  
  "/aws/service/global-infrastructure/availability-zones/ape1-az2",  
  "/aws/service/global-infrastructure/availability-zones/ape1-az3",  
  "/aws/service/global-infrastructure/availability-zones/apne1-az1",  
  "/aws/service/global-infrastructure/availability-zones/apne1-az2",  
  "/aws/service/global-infrastructure/availability-zones/apne1-az3",  
  "/aws/service/global-infrastructure/availability-zones/apne1-az4"
```

## View names of Availability Zones in a single Region

You can view the names of the Availability Zones in one Region (us-east-2, in this example) using the following command.

### Linux & macOS

```
aws ssm get-parameters-by-path \  
  --path /aws/service/global-infrastructure/regions/us-east-2/availability-zones \  
  --query 'Parameters[].Name | sort(@)'
```

## Windows

```
aws ssm get-parameters-by-path ^
  --path /aws/service/global-infrastructure/regions/us-east-2/availability-zones ^
  --query "Parameters[].Name | sort(@)"
```

The command returns information like the following.

```
[
  "/aws/service/global-infrastructure/regions/us-east-2/availability-zones/use2-az1",
  "/aws/service/global-infrastructure/regions/us-east-2/availability-zones/use2-az2",
  "/aws/service/global-infrastructure/regions/us-east-2/availability-zones/use2-az3"
```

## View Availability Zone ARNs only

You can view the Amazon Resource Names (ARNs) of Availability Zones only by using the following command.

### Linux & macOS

```
aws ssm get-parameters-by-path \
  --path /aws/service/global-infrastructure/availability-zones \
  --query 'Parameters[].ARN | sort(@)'
```

## Windows

```
aws ssm get-parameters-by-path ^
  --path /aws/service/global-infrastructure/availability-zones ^
  --query "Parameters[].ARN | sort(@)"
```

The command returns information like the following. This example has been truncated for space.

```
[
  "arn:aws:ssm:us-east-2::parameter/aws/service/global-infrastructure/availability-
  zones/afs1-az1",
  "arn:aws:ssm:us-east-2::parameter/aws/service/global-infrastructure/availability-
  zones/afs1-az2",
  "arn:aws:ssm:us-east-2::parameter/aws/service/global-infrastructure/availability-
  zones/afs1-az3",
```

```
"arn:aws:ssm:us-east-2::parameter/aws/service/global-infrastructure/availability-zones/ape1-az1",
"arn:aws:ssm:us-east-2::parameter/aws/service/global-infrastructure/availability-zones/ape1-az2",
"arn:aws:ssm:us-east-2::parameter/aws/service/global-infrastructure/availability-zones/ape1-az3",
"arn:aws:ssm:us-east-2::parameter/aws/service/global-infrastructure/availability-zones/apne1-az1",
```

## View local zone details

You can view local zones by using the following command.

### Linux & macOS

```
aws ssm get-parameters-by-path \
  --path /aws/service/global-infrastructure/local-zones
```

### Windows

```
aws ssm get-parameters-by-path ^
  --path /aws/service/global-infrastructure/local-zones
```

The command returns information like the following. This example has been truncated for space.

```
{
  "Parameters": [
    {
      "Name": "/aws/service/global-infrastructure/local-zones/afs1-los1-az1",
      "Type": "String",
      "Value": "afs1-los1-az1",
      "Version": 1,
      "LastModifiedDate": "2023-01-25T11:53:11.690000-05:00",
      "ARN": "arn:aws:ssm:us-east-2::parameter/aws/service/global-infrastructure/
local-zones/afs1-los1-az1",
      "DataType": "text"
    },
    {
      "Name": "/aws/service/global-infrastructure/local-zones/apne1-tpe1-az1",
      "Type": "String",
      "Value": "apne1-tpe1-az1",
      "Version": 1,
```

```

        "LastModifiedDate": "2024-03-15T12:35:41.076000-04:00",
        "ARN": "arn:aws:ssm:us-east-2::parameter/aws/service/global-infrastructure/
local-zones/apne1-tpe1-az1",
        "DataType": "text"
    },
    {
        "Name": "/aws/service/global-infrastructure/local-zones/aps1-ccu1-az1",
        "Type": "String",
        "Value": "aps1-ccu1-az1",
        "Version": 1,
        "LastModifiedDate": "2022-12-19T11:34:43.351000-05:00",
        "ARN": "arn:aws:ssm:us-east-2::parameter/aws/service/global-infrastructure/
local-zones/aps1-ccu1-az1",
        "DataType": "text"
    }
]
}

```

## View Wavelength Zone details

You can view Wavelength Zones by using the following command.

### Linux & macOS

```
aws ssm get-parameters-by-path \
  --path /aws/service/global-infrastructure/wavelength-zones
```

### Windows

```
aws ssm get-parameters-by-path ^
  --path /aws/service/global-infrastructure/wavelength-zones
```

The command returns information like the following. This example has been truncated for space.

```

{
  "Parameters": [
    {
      "Name": "/aws/service/global-infrastructure/wavelength-zones/apne1-wl1-nrt-
wlz1",
      "Type": "String",
      "Value": "apne1-wl1-nrt-wlz1",
      "Version": 3,

```

```

        "LastModifiedDate": "2020-12-15T17:16:04.715000-05:00",
        "ARN": "arn:aws:ssm:us-east-2::parameter/aws/service/global-infrastructure/
wavelength-zones/apne1-wl1-nrt-wlz1",
        "DataType": "text"
    },
    {
        "Name": "/aws/service/global-infrastructure/wavelength-zones/apne2-wl1-sel-
wlz1",
        "Type": "String",
        "Value": "apne2-wl1-sel-wlz1",
        "Version": 1,
        "LastModifiedDate": "2022-05-25T12:29:13.862000-04:00",
        "ARN": "arn:aws:ssm:us-east-2::parameter/aws/service/global-infrastructure/
wavelength-zones/apne2-wl1-sel-wlz1",
        "DataType": "text"
    },
    {
        "Name": "/aws/service/global-infrastructure/wavelength-zones/cac1-wl1-yto-
wlz1",
        "Type": "String",
        "Value": "cac1-wl1-yto-wlz1",
        "Version": 1,
        "LastModifiedDate": "2022-04-26T09:57:44.495000-04:00",
        "ARN": "arn:aws:ssm:us-east-2::parameter/aws/service/global-infrastructure/
wavelength-zones/cac1-wl1-yto-wlz1",
        "DataType": "text"
    }
]
}

```

## View all parameters and values under a local zone

You can view all parameter data for a local zone by using the following command.

### Linux & macOS

```
aws ssm get-parameters-by-path \
  --path "/aws/service/global-infrastructure/local-zones/usw2-lax1-az1/"
```

### Windows

```
aws ssm get-parameters-by-path ^
  --path "/aws/service/global-infrastructure/local-zones/use1-bos1-az1"
```

The command returns information like the following. This example has been truncated for space.

```
{
  "Parameters": [
    {
      "Name": "/aws/service/global-infrastructure/local-zones/use1-bos1-az1/
geolocationCountry",
      "Type": "String",
      "Value": "US",
      "Version": 3,
      "LastModifiedDate": "2020-12-15T14:16:17.641000-08:00",
      "ARN": "arn:aws:ssm:us-east-2::parameter/aws/service/global-infrastructure/
local-zones/use1-bos1-az1/geolocationCountry",
      "DataType": "text"
    },
    {
      "Name": "/aws/service/global-infrastructure/local-zones/use1-bos1-az1/
geolocationRegion",
      "Type": "String",
      "Value": "US-MA",
      "Version": 3,
      "LastModifiedDate": "2020-12-15T14:16:17.794000-08:00",
      "ARN": "arn:aws:ssm:us-east-2::parameter/aws/service/global-infrastructure/
local-zones/use1-bos1-az1/geolocationRegion",
      "DataType": "text"
    },
    {
      "Name": "/aws/service/global-infrastructure/local-zones/use1-bos1-az1/
location",
      "Type": "String",
      "Value": "US East (Boston)",
      "Version": 1,
      "LastModifiedDate": "2021-01-11T10:53:24.634000-08:00",
      "ARN": "arn:aws:ssm:us-east-2::parameter/aws/service/global-infrastructure/
local-zones/use1-bos1-az1/location",
      "DataType": "text"
    },
    {
      "Name": "/aws/service/global-infrastructure/local-zones/use1-bos1-az1/
network-border-group",
      "Type": "String",
      "Value": "us-east-1-bos-1",
      "Version": 3,
      "LastModifiedDate": "2020-12-15T14:16:20.641000-08:00",
```

```

        "ARN": "arn:aws:ssm:us-east-2::parameter/aws/service/global-infrastructure/
local-zones/use1-bos1-az1/network-border-group",
        "DataType": "text"
    },
    {
        "Name": "/aws/service/global-infrastructure/local-zones/use1-bos1-az1/
parent-availability-zone",
        "Type": "String",
        "Value": "use1-az4",
        "Version": 3,
        "LastModifiedDate": "2020-12-15T14:16:20.834000-08:00",
        "ARN": "arn:aws:ssm:us-east-2::parameter/aws/service/global-infrastructure/
local-zones/use1-bos1-az1/parent-availability-zone",
        "DataType": "text"
    },
    {
        "Name": "/aws/service/global-infrastructure/local-zones/use1-bos1-az1/
parent-region",
        "Type": "String",
        "Value": "us-east-1",
        "Version": 3,
        "LastModifiedDate": "2020-12-15T14:16:20.721000-08:00",
        "ARN": "arn:aws:ssm:us-east-2::parameter/aws/service/global-infrastructure/
local-zones/use1-bos1-az1/parent-region",
        "DataType": "text"
    },
    {
        "Name": "/aws/service/global-infrastructure/local-zones/use1-bos1-az1/zone-
group",
        "Type": "String",
        "Value": "us-east-1-bos-1",
        "Version": 3,
        "LastModifiedDate": "2020-12-15T14:16:17.983000-08:00",
        "ARN": "arn:aws:ssm:us-east-2::parameter/aws/service/global-infrastructure/
local-zones/use1-bos1-az1/zone-group",
        "DataType": "text"
    }
]
}

```

## View local zone parameter names only

You can view just the names of local zone parameters by using the following command.

## Linux & macOS

```
aws ssm get-parameters-by-path \  
  --path /aws/service/global-infrastructure/local-zones/usw2-lax1-az1 \  
  --query 'Parameters[].Name | sort(@)'
```

## Windows

```
aws ssm get-parameters-by-path ^  
  --path /aws/service/global-infrastructure/local-zones/use1-bos1-az1 ^  
  --query "Parameters[].Name | sort(@)"
```

The command returns information like the following.

```
[  
  "/aws/service/global-infrastructure/local-zones/use1-bos1-az1/geolocationCountry",  
  "/aws/service/global-infrastructure/local-zones/use1-bos1-az1/geolocationRegion",  
  "/aws/service/global-infrastructure/local-zones/use1-bos1-az1/location",  
  "/aws/service/global-infrastructure/local-zones/use1-bos1-az1/network-border-  
group",  
  "/aws/service/global-infrastructure/local-zones/use1-bos1-az1/parent-availability-  
zone",  
  "/aws/service/global-infrastructure/local-zones/use1-bos1-az1/parent-region",  
  "/aws/service/global-infrastructure/local-zones/use1-bos1-az1/zone-group"  
]
```

## Parameter Store walkthroughs

The walkthrough in this section shows you how to create, store, and run parameters with Parameter Store, a capability of AWS Systems Manager, in a test environment. This walkthrough shows you how to use Parameter Store with other Systems Manager capabilities. You can also use Parameter Store with other AWS services. For more information, see [What is a parameter?](#).

### Contents

- [Creating a SecureString parameter in Parameter Store and joining a node to a Domain \(PowerShell\)](#)
- [Using Parameter Store parameters in Amazon Elastic Kubernetes Service](#)

## Creating a SecureString parameter in Parameter Store and joining a node to a Domain (PowerShell)

This walkthrough shows how to join a Windows Server node to a domain using AWS Systems Manager SecureString parameters and Run Command. The walkthrough uses typical domain parameters, such as the domain name and a domain user name. These values are passed as unencrypted string values. The domain password is encrypted using an AWS managed key and passed as an encrypted string.

### Prerequisites

This walkthrough assumes that you already specified your domain name and DNS server IP address in the DHCP option set that is associated with your Amazon VPC. For information, see [Working with DHCP Options Sets](#) in the *Amazon VPC User Guide*.

### To create a SecureString parameter and join a node to a domain

1. Enter parameters into the system using AWS Tools for Windows PowerShell.

In the following commands, replace each *user input placeholder* with your own information.

```
Write-SSMParameter -Name "domainName" -Value "DOMAIN-NAME" -Type String
Write-SSMParameter -Name "domainJoinUserName" -Value "DOMAIN\USERNAME" -Type String
Write-SSMParameter -Name "domainJoinPassword" -Value "PASSWORD" -Type SecureString
```

#### Important

Only the *value* of a SecureString parameter is encrypted. Parameter names, descriptions, and other properties aren't encrypted.

2. Attach the following AWS Identity and Access Management (IAM) policies to the IAM role permissions for your node:
  - **AmazonSSMManagedInstanceCore** – Required. This AWS managed policy allows a managed node to use Systems Manager service core functionality.
  - **AmazonSSMDirectoryServiceAccess** – Required. This AWS managed policy allows SSM Agent to access AWS Directory Service on your behalf for requests to join the domain by the managed node.

- **A custom policy for S3 bucket access** – Required. SSM Agent, which is on your node and performs Systems Manager tasks, requires access to specific Amazon-owned Amazon Simple Storage Service (Amazon S3) buckets. In the custom S3 bucket policy that you create, you also provide access to S3 buckets of your own that are necessary for Systems Manager operations.

Examples: You can write output for Run Command commands or Session Manager sessions to an S3 bucket, and then use this output later for auditing or troubleshooting. You store access scripts or custom patch baseline lists in an S3 bucket, and then reference the script or list when you run a command, or when a patch baseline is applied.

For information about creating a custom policy for Amazon S3 bucket access, see [Create a custom S3 bucket policy for an instance profile](#)

**Note**

Saving output log data in an S3 bucket is optional, but we recommend setting it up at the beginning of your Systems Manager configuration process if you have decided to use it. For more information, see [Create a Bucket](#) in the *Amazon Simple Storage Service User Guide*.

- **CloudWatchAgentServerPolicy** – Optional. This AWS managed policy allows you to run the CloudWatch agent on managed nodes. This policy makes it possible to read information on a node and write it to Amazon CloudWatch. Your instance profile needs this policy only if you use services such as Amazon EventBridge or CloudWatch Logs.

**Note**

Using CloudWatch and EventBridge features is optional, but we recommend setting them up at the beginning of your Systems Manager configuration process if you have decided to use them. For more information, see the [Amazon EventBridge User Guide](#) and the [Amazon CloudWatch Logs User Guide](#).

3. Edit the IAM role attached to the node and add the following policy. This policy gives the node permissions to call the `kms:Decrypt` and the `ssm:CreateDocument` API.

```
{  
  "Version": "2012-10-17",
```

```

    "Statement": [
      {
        "Effect": "Allow",
        "Action": [
          "kms:Decrypt",
          "ssm:CreateDocument"
        ],
        "Resource": [
          "arn:aws:kms:region:account-id:key/kms-key-id"
        ]
      }
    ]
  }
}

```

4. Copy and paste the following json text into a text editor and save the file as `JoinInstanceToDomain.json` in the following location: `c:\temp\JoinInstanceToDomain.json`.

```

{
  "schemaVersion": "2.2",
  "description": "Run a PowerShell script to securely join a Windows Server instance to a domain",
  "mainSteps": [
    {
      "action": "aws:runPowerShellScript",
      "name": "runPowerShellWithSecureString",
      "precondition": {
        "StringEquals": [
          "platformType",
          "Windows"
        ]
      },
      "inputs": {
        "runCommand": [
          "$domain = (Get-SSMParameterValue -Name domainName).Parameters[0].Value",
          "if ((gwmi Win32_ComputerSystem).domain -eq $domain){write-host \"Computer is part of $domain, exiting\"; exit 0}",
          "$username = (Get-SSMParameterValue -Name domainJoinUserName).Parameters[0].Value",
          "$password = (Get-SSMParameterValue -Name domainJoinPassword -WithDecryption $True).Parameters[0].Value | ConvertTo-SecureString -asPlainText -Force",

```

```

        "$credential = New-Object
        System.Management.Automation.PSCredential($username,$password)",
        "Add-Computer -DomainName $domain -Credential $credential -
ErrorAction SilentlyContinue -ErrorVariable domainjoinerror",
        "if($?) {Write-Host \"Instance joined to domain successfully.
Restarting\"; exit 3010} else {Write-Host \"Instance failed to join domain with
error:\" $domainjoinerror; exit 1 }"
    ]
}
]
}
}

```

5. Run the following command in Tools for Windows PowerShell to create a new SSM document.

```

$json = Get-Content C:\temp\JoinInstanceToDomain | Out-String
New-SSMDocument -Name JoinInstanceToDomain -Content $json -DocumentType Command

```

6. Run the following command in Tools for Windows PowerShell to join the node to the domain.

```

Send-SSMCommand -InstanceId instance-id -DocumentName JoinInstanceToDomain

```

If the command succeeds, the system returns information similar to the following.

```

WARNING: The changes will take effect after you restart the computer EC2ABCD-
EXAMPLE.
Domain join succeeded, restarting
Computer is part of example.local, exiting

```

If the command fails, the system returns information similar to the following.

```

Failed to join domain with error:
Computer 'EC2ABCD-EXAMPLE' failed to join domain 'example.local'
from its current workgroup 'WORKGROUP' with following error message:
The specified domain either does not exist or could not be contacted.

```

## Using Parameter Store parameters in Amazon Elastic Kubernetes Service

To show secrets from Secrets Manager and parameters from Parameter Store as files mounted in [Amazon EKS](#) pods, you can use the AWS Secrets and Configuration Provider (ASCP) for the

[Kubernetes Secrets Store CSI Driver](#). (Parameter Store is a capability of AWS Systems Manager.)

The ASCP works with Amazon Elastic Kubernetes Service (Amazon EKS) 1.17+. AWS Fargate node groups are not supported.

With the ASCP, you can retrieve parameters that are stored and managed in Parameter Store. Then you can use the parameters in your workloads running on Amazon EKS. If your parameter contains multiple key value pairs in JSON format, you can optionally choose to mount them in Amazon EKS. The ASCP can use JMESPath syntax to query the key value pairs in your parameter.

You can use AWS Identity and Access Management (IAM) roles and policies to limit access to your parameters to specific Amazon EKS pods in a cluster. The ASCP retrieves the pod identity and exchanges the identity for an IAM role. ASCP assumes the IAM role of the pod. Then it can retrieve parameters from Parameter Store that are authorized for that role.

To learn how to integrate Secrets Manager with Amazon EKS, see [Using Secrets Manager secrets in Amazon Elastic Kubernetes Service](#).

## Installing the ASCP

The ASCP is available on GitHub in the [secrets-store-csi-driver-provider-aws](#) repository. The repository also contains example YAML files for creating and mounting a secret. You first install the Kubernetes Secrets Store CSI Driver, and then you install the ASCP.

### To install the Kubernetes Secrets Store CSI Driver and the ASCP

1. To install the Kubernetes Secrets Store CSI Driver, run the following commands. For full installation instructions, see [Installation](#) in the Kubernetes Secrets Store CSI Driver Book. For information about installing Helm, see [Using Helm with Amazon EKS](#).

```
helm repo add secrets-store-csi-driver https://kubernetes-sigs.github.io/secrets-store-csi-driver/charts
helm install -n kube-system csi-secrets-store secrets-store-csi-driver/secrets-store-csi-driver
```

2. To install the ASCP, use the YAML file in the GitHub repository deployment directory. For information about installing `kubectl`, see [Installing kubectl](#).

```
kubectl apply -f https://raw.githubusercontent.com/aws/secrets-store-csi-driver-provider-aws/main/deployment/aws-provider-installer.yaml
```

## Step 1: Set up access control

To grant your Amazon EKS pod access to parameters in Parameter Store, you first create a policy that limits access to the parameters that the pod needs to access. Then you create an [IAM role for service account](#) and attach the policy to it. For more information about restricting access to Systems Manager parameters using IAM policies, see [Restricting access to Parameter Store parameters using IAM policies](#).

### Note

When using Parameter Store parameters, the permission `ssm:GetParameters` is needed in the policy.

The ASCP retrieves the pod identity and exchanges it for the IAM role. ASCP assumes the IAM role of the pod, which gives it access to the parameters you authorized. Other containers can't access the parameters unless you also associate them with the IAM role.

## Step 2: Mount parameters in Amazon EKS

To show parameters in Amazon EKS as though they are files on the filesystem, you create a `SecretProviderClass` YAML file that contains information about your parameters and how to mount them in the Amazon EKS pod.

The `SecretProviderClass` must be in the same namespace as the Amazon EKS pod it references.

### **SecretProviderClass**

The `SecretProviderClass` YAML has the following format.

```
apiVersion: secrets-store.csi.x-k8s.io/v1alpha1
kind: SecretProviderClass
metadata:
  name: <NAME>
spec:
  provider: aws
  parameters:
```

## parameters

Contains the details of the mount request.

### objects

A string containing a YAML declaration of the parameters to be mounted. We recommend using a YAML multi-line string or pipe (|) character.

### objectName

The friendly name of the parameter. This becomes the file name of the parameter in the Amazon EKS pod unless you specify `objectAlias`. For Parameter Store this must be the Name of the parameter, and cannot be a full Amazon Resource Name (ARN).

### jmesPath

(Optional) A map of the keys in the JSON encoded parameter to the files to be mounted in Amazon EKS. The following example shows what a JSON encoded parameter looks like.

```
{
  "username" : "myusername",
  "password" : "mypassword"
}
```

The keys are `username` and `password`. The value associated with `username` is `myusername`, and the value associated with `password` is `mypassword`.

### path

The key in the parameter.

### objectAlias

The file name to be mounted in the Amazon EKS pod.

### objectType

For Parameter Store, this field is required. Use `ssmparameter`.

### objectAlias

(Optional) The file name of the parameter in the Amazon EKS pod. If you don't specify this field, the `objectName` appears as the file name.

## **objectVersion**

(Optional) The version number of the parameter. We recommend that you don't use this field because you must update it every time you update the parameter. By default, the most recent version is used. For Parameter Store parameters, you can use `objectVersion` or `objectVersionLabel` but not both.

## **objectVersionLabel**

(Optional) The parameter label for the version. The default is the most recent version. For Parameter Store parameters, you can use `objectVersion` or `objectVersionLabel` but not both.

## **region**

(Optional) The AWS Region of the parameter. If you don't use this field, the ASCP looks up the Region from the annotation on the node. This lookup adds overhead to mount requests, so we recommend that you provide the Region for clusters that use large numbers of pods.

## **pathTranslation**

(Optional) A single substitution character to use if the file name (either `objectName` or `objectAlias`) contains the path separator character, such as slash (/) on Linux. If a parameter name contains the path separator, the ASCP can't create a mounted file with that name. Instead, you can replace the path separator character with a different character by entering it in this field. If you don't use this field, the default is underscore (\_), so for example, `My/Path/Parameter` mounts as `My_Path_Parameter`.

To prevent character substitution, enter the string `False`.

## **Example**

The following example configuration shows a `SecretProviderClass` with a Parameter Store parameter resource.

```
apiVersion: secrets-store.csi.x-k8s.io/v1alpha1
kind: SecretProviderClass
metadata:
  name: aws-secrets
spec:
  provider: aws
  parameters:
```

```
objects: |
  - objectName: "MyParameter"
    objectType: "ssmparameter"
```

### Step 3: Update the deployment YAML

Update your deployment YAML to use the `secrets-store.csi.k8s.io` driver and reference the `SecretProviderClass` resource created in the previous step. This ensures your cluster is using the Secrets Store CSI driver.

Below is a sample deployment YAML using a `SecretProviderClass` named `aws-secrets`.

```
volumes:
  - name: secrets-store-inline
    csi:
      driver: secrets-store.csi.k8s.io
      readOnly: true
      volumeAttributes:
        secretProviderClass: "aws-secrets"
```

### Tutorial: Creating and mounting a parameter in an Amazon EKS pod

In this tutorial, you create an example parameter in Parameter Store, and then you mount the parameter in an Amazon EKS pod and deploy it.

Before you begin, install the ASCP. For more information, see [the section called “Installing the ASCP”](#).

#### To create and mount a secret

1. Set the AWS Region and the name of your cluster as shell variables so you can use them in bash commands. For *region*, enter the AWS Region where your Amazon EKS cluster runs. For *clustername*, enter the name of your cluster.

```
REGION=region
CLUSTERNAME=clustername
```

2. Create a test parameter.

```
aws ssm put-parameter --name "MyParameter" --value "EKS parameter" --type String --
region "$REGION"
```

3. Create a resource policy for the pod that limits its access to the parameter you created in the previous step. For *parameter-arn*, use the ARN of the parameter. Save the policy ARN in a shell variable. To retrieve the parameter ARN, use `get-parameter`.

```
POLICY_ARN=$(aws --region "$REGION" --query Policy.Arn --output text iam create-policy --policy-name nginx-parameter-deployment-policy --policy-document '{
  "Version": "2012-10-17",
  "Statement": [ {
    "Effect": "Allow",
    "Action": ["ssm:GetParameter", "ssm:GetParameters"],
    "Resource": ["parameter-arn"]
  } ]
}')

```

4. Create an IAM OpenID Connect (OIDC) provider for the cluster if you don't already have one. For more information, see [Create an IAM OIDC provider for your cluster](#).

```
eksctl utils associate-iam-oidc-provider --region="$REGION" --
cluster="$CLUSTERNAME" --approve # Only run this once

```

5. Create the service account the pod uses, and associate the resource policy you created in step 3 with that service account. For this tutorial, for the service account name, you use *nginx-deployment-sa*. For more information, see [Create an IAM role for a service account](#).

```
eksctl create iamserviceaccount --name nginx-deployment-sa --region="$REGION" --
cluster "$CLUSTERNAME" --attach-policy-arn "$POLICY_ARN" --approve --override-
existing-serviceaccounts

```

6. Create the `SecretProviderClass` to specify which parameter to mount in the pod. The following command uses the file location of a `SecretProviderClass` file named `ExampleSecretProviderClass.yaml`. For information about creating your own `SecretProviderClass`, see [the section called "SecretProviderClass"](#).

```
kubectl apply -f ./ExampleSecretProviderClass.yaml

```

7. Deploy your pod. The following command uses a deployment file named `ExampleDeployment.yaml`. For information about creating your own `SecretProviderClass`, see [the section called "Step 3: Update the deployment YAML"](#).

```
kubectl apply -f ./ExampleDeployment.yaml

```

8. To verify the parameter has been mounted properly, use the following command and confirm that your parameter value appears.

```
kubectl exec -it $(kubectl get pods | awk '/nginx-deployment/{print $1}' | head -1)
cat /mnt/secrets-store/MyParameter; echo
```

The parameter value appears.

```
"EKS parameter"
```

## Troubleshooting

You can view most errors by describing the pod deployment.

### To see error messages for your container

1. Get a list of pod names with the following command. If you aren't using the default namespace, use `-n <NAMESPACE>`.

```
kubectl get pods
```

2. To describe the pod, in the following command, for *pod-id* use the pod ID from the pods you found in the previous step. If you aren't using the default namespace, use `-n <NAMESPACE>`.

```
kubectl describe pod/pod-id
```

### To see errors for the ASCP

- To find more information in the provider logs, in the following command, for *pod-id* use the ID of the `csi-secrets-store-provider-aws` pod.

```
kubectl -n kube-system get pods
kubectl -n kube-system logs pod/pod-id
```

## Auditing and logging Parameter Store activity

AWS CloudTrail captures API calls made in the AWS Systems Manager console, the AWS Command Line Interface (AWS CLI), and the Systems Manager SDK. You can view the information in the CloudTrail console or in an Amazon Simple Storage Service (Amazon S3) bucket. All CloudTrail logs for your account use one bucket. For more information about viewing and using CloudTrail logs of Systems Manager activity, see [Logging AWS Systems Manager API calls with AWS CloudTrail](#). For more information about auditing and logging options for Systems Manager, see [Monitoring AWS Systems Manager](#).

## Troubleshooting Parameter Store

Use the following information to help you troubleshoot problems with Parameter Store, a capability of AWS Systems Manager.

### Troubleshooting `aws:ec2:image` parameter creation

Use the following information to help troubleshoot problems with creating `aws:ec2:image` data type parameters.

#### No permission to create an instance

**Problem:** You try to create an instance using an `aws:ec2:image` parameter but receive an error message such as "You are not authorized to perform this operation."

- **Solution:** You do not have all the permissions needed to create an EC2 instance using a parameter value, such as permissions for `ec2:RunInstances`, `ec2:DescribeImages`, and `ssm:GetParameter`, among others. Contact a user with administrator permissions in your organization to request the necessary permissions.

#### EventBridge reports the failure message "Unable to Describe Resource"

**Problem:** You ran a command to create an `aws:ec2:image` parameter, but parameter creation failed. You receive a notification from Amazon EventBridge that reports the exception "Unable to Describe Resource".

**Solution:** This message can indicate the following:

- You do not have all the permissions needed for the `ec2:DescribeImages` API operation, or you lack permission to access the specific image referenced in the parameter. Contact a user with administrator permissions in your organization to request the necessary permissions.

- The Amazon Machine Image (AMI) ID you entered as a parameter value isn't valid. Make sure you're entering the ID of an AMI that is available in the current AWS Region and account you're working in.

### New `aws:ec2:image` parameter isn't available

**Problem:** You just ran a command to create an `aws:ec2:image` parameter and a version number was reported, but the parameter isn't available.

- **Solution:** When you run the command to create a parameter that uses the `aws:ec2:image` data type, a version number is generated for the parameter right away, but the parameter format must be validated before the parameter is available. This process can take up to a few minutes. To monitor the parameter creation and validation process, you can do the following:
  - Use EventBridge to send you notifications about your create and update parameter operations. These notifications report whether a parameter operation was successful or not. For information about subscribing to Parameter Store events in EventBridge, see [Setting up notifications or triggering actions based on Parameter Store events](#).
  - In the Parameter Store section of the Systems Manager console, refresh the list of parameters periodically to search for the new or updated parameter details.
  - Use the **GetParameter** command to check for the new or updated parameter. For example, using the AWS Command Line Interface (AWS CLI):

```
aws ssm get-parameter name MyParameter
```

For a new parameter, a `ParameterNotFound` message is returned until the parameter is validated. For an existing parameter that you're updating, information about the new version isn't included until the parameter is validated.

If you attempt to create or update the parameter again before the validation process is complete, the system reports that validation is still in process. If the parameter isn't created or updated, you can try again after 5 minutes have passed from the original attempt.

## AWS Systems Manager change management tools

AWS Systems Manager provides the following capabilities for making changes to your AWS resources.

## Topics

- [AWS Systems Manager Change Manager](#)
- [AWS Systems Manager Automation](#)
- [AWS Systems Manager Change Calendar](#)
- [AWS Systems Manager Maintenance Windows](#)

## AWS Systems Manager Change Manager

Change Manager, a capability of AWS Systems Manager, is an enterprise change management framework for requesting, approving, implementing, and reporting on operational changes to your application configuration and infrastructure. From a single *delegated administrator account*, if you use AWS Organizations, you can manage changes across multiple AWS accounts and across AWS Regions. Alternatively, using a *local account*, you can manage changes for a single AWS account. Use Change Manager for managing changes to both AWS resources and on-premises resources. To get started with Change Manager, open the [Systems Manager console](#). In the navigation pane, choose **Change Manager**.

With Change Manager, you can use pre-approved *change templates* to help automate change processes for your resources and help avoid unintentional results when making operational changes. Each change template specifies the following:

- One or more Automation runbooks for a user to choose from when creating a change request. The changes that are made to your resources are defined in Automation runbooks. You can include custom runbooks or [AWS managed runbooks](#) in the change templates you create. When a user creates a change request, they can choose which one of the available runbooks to include in the request. Additionally, you can create change templates that let the user making the request specify any runbook in the change request.
- The users in the account who must review change requests that were made using that change template.
- The Amazon Simple Notification Service (Amazon SNS) topic that is used to notify assigned approvers that a change request is ready for review.
- The Amazon CloudWatch alarm that is used to monitor the runbook workflow.
- The Amazon SNS topic that is used to send notifications about status changes for change requests that are created using the change template.

- The tags to apply to the change template for use in categorizing and filtering your change templates.
- Whether change requests created from the change template can be run without an approval step (auto-approved requests).

Through its integration with Change Calendar, which is another capability of Systems Manager, Change Manager also helps you safely implement changes while avoiding schedule conflicts with important business events. Change Manager integration with AWS Organizations and AWS IAM Identity Center helps you manage changes across your organization from a single account using your existing identity management system. You can monitor change progress from Change Manager and audit operational changes across your organization, providing improved visibility and accountability.

Change Manager complements the safety controls of your [continuous integration](#) (CI) practices and [continuous delivery](#) (CD) methodology. Change Manager isn't intended for changes made as part of an automated release process, such as a CI/CD pipeline, unless there is an exception or approval required.

## How Change Manager works

When the need for a standard or emergency operational change is identified, someone in the organization creates a change request that is based on one of the change templates created for use in your organization or account.

If the requested change requires manual approvals, Change Manager notifies the designated approvers through an Amazon SNS notification that a change request is ready for their review. You can designate approvers for change requests in the change template, or let users designate approvers in the change request itself. You can assign different reviewers to different templates. For example, assign one user, user group, or AWS Identity and Access Management (IAM) role who must approve requests for changes to managed nodes, and another user, group, or IAM role for database changes. If the change template allows auto-approvals, and a requester's user policy doesn't prohibit it, the user can also choose to run the Automation runbook for their request without a review step (with the exception of change freeze events).

For each change template, you can add up to five levels of approvers. For example, you might require technical reviewers to approve a change request created from a change template first, and then require a second level of approvals from one or more managers.

Change Manager is integrated with [AWS Systems Manager Change Calendar](#). When a requested change is approved, the system first determines whether the request conflicts with other scheduled business activities. If a conflict is detected, Change Manager can block the change or require additional approvals before starting the runbook workflow. For example, you might allow changes only during business hours to ensure that teams are available to manage any unexpected problems. For any changes requested to run outside those hours, you can require higher-level management approval in the form of *change freeze approvers*. For emergency changes, Change Manager can skip the step of checking Change Calendar for conflicts or blocking events after a change request is approved.

When it's time to implement an approved change, Change Manager runs the Automation runbook that is specified in the associated change request. Only the operations defined in approved change requests are permitted when runbook workflows run. This approach helps you avoid unintentional results while changes are being implemented.

In addition to restricting the changes that can be made when a runbook workflow runs, Change Manager also helps you control concurrency and error thresholds. You choose how many resources a runbook workflow can run on at once, how many accounts the change can run in at once, and how many failures to allow before the process is stopped and (if the runbook includes a rollback script) rolled back. You can also monitor the progress of changes being made by using CloudWatch alarms.

After a runbook workflow has completed, you can review details about the changes made. These details include the reason for a change request, which change template was used, who requested and approved the changes, and how the changes were implemented.

## More info

[Introducing AWS Systems Manager Change Manager](#) on the *AWS News Blog*

## How can Change Manager benefit my operations?

Benefits of Change Manager include the following:

- **Reduce risk of service disruption and downtime**

Change Manager can make operational changes safer by ensuring that only approved changes are implemented when a runbook workflow runs. You can block unplanned and unreviewed

changes. Change Manager helps you avoid the types of unintentional results caused by human error that require costly hours of research and backtracking.

- **Get detailed auditing and reporting on change histories**

Change Manager provides accountability with a consistent way to report and audit changes made across your organization, the intent of the changes, and details about who approved and implemented them.

- **Avoid schedule conflicts or violations**

Change Manager can detect schedule conflicts such as holiday events or new product launches, based on the active change calendar for your organization. You can allow runbook workflows to run only during business hours, or allow them only with additional approvals.

- **Adapt change requirements to your changing business**

During different business periods, you can implement different change management requirements. For example, during end-of-month reporting, tax season, or other critical business periods, you can block changes or require director-level approval for changes that could introduce unnecessary operational risks.

- **Centrally manage changes across accounts**

Through its integration with Organizations, Change Manager makes it possible for you to manage changes throughout all of your organizational units (OUs) from a single delegated administrator account. You can turn on Change Manager for use with your entire organization or with only some of your OUs.

## Who should use Change Manager?

Change Manager is appropriate for the following AWS customers and organizations:

- Any AWS customer who wants to improve the safety and governance of operational changes made to their cloud or on-premises environments.
- Organizations that want to increase collaboration and visibility across teams, improve application availability by avoiding downtime, and reduce the risk associated with manual and repetitive tasks.
- Organizations that must comply with best practices for change management.
- Customers who need a fully auditable history of changes made to their application configuration and infrastructure.

## What are the main features of Change Manager?

Primary features of Change Manager include the following:

- **Integrated support for change management best practices**

With Change Manager, you can apply select change management best practices to your operations. You can choose to turn on the following options:

- Check Change Calendar to see if events are currently restricted so changes are made only during open calendar periods.
- Allow changes during restricted events with extra approvals from change freeze approvers.
- Require CloudWatch alarms to be specified for all change templates.
- Require all change templates created in your account to be reviewed and approved before they can be used to create change requests.

- **Different approval paths for closed calendar periods and emergency change requests**

You can allow an option to check Change Calendar for restricted events and block approved change requests until the event is complete. However, you can also designate a second group of approvers, change freeze approvers, who can permit the change to be made even if the calendar is closed. You can also create emergency change templates. Change requests created from an emergency change template still require regular approvals but aren't subject to calendar restrictions and don't require change freeze approvals.

- **Control how and when runbook workflows are started**

Runbook workflows can be started according to a schedule, or as soon as approvals are complete (subject to calendar restriction rules).

- **Built-in notification support**

Specify who in your organization should review and approve change templates and change requests. Assign an Amazon SNS topic to a change template to send notifications to the topic's subscribers about status changes for change requests created with that change template.

- **Integration with AWS Systems Manager Change Calendar**

Change Manager allows administrators to restrict scheduling changes during specified time periods. For instance, you can create a policy that allows changes only during business hours to ensure that the team is available to handle any issues. You can also restrict changes during

important business events. For example, retail businesses might restrict changes during large sales events. You can also require additional approvals during restricted periods.

- **Integration with AWS IAM Identity Center and Active Directory support**

With IAM Identity Center integration, members of your organization can access AWS accounts and manage their resources using Systems Manager based on a common user identity. Using IAM Identity Center, you can assign your users access to accounts across AWS.

Integration with Active Directory makes it possible to assign users in your Active Directory account as approvers for change templates created for your Change Manager operations.

- **Integration with Amazon CloudWatch alarms**

Change Manager is integrated with CloudWatch alarms. Change Manager listens for CloudWatch alarms during the runbook workflow and takes any actions, including sending notifications, that are defined for the alarm.

- **Integration with AWS CloudTrail Lake**

By creating an event data store in AWS CloudTrail Lake, you can view auditable information about the changes made by change requests that run in your account or organization. The event information stored includes such details as the following:

- The API actions that were run
- The request parameters included for those actions
- The user that ran the action
- The resources that were updated during the process

- **Integration with AWS Organizations**

Using the cross-account capabilities provided by Organizations, you can use a delegated administrator account for managing Change Manager operations in OUs in your organization. In your Organizations management account, you can specify which account is to be the delegated administrator account. You can also control which of your OUs Change Manager can be used in.

## **Is there a charge to use Change Manager?**

Yes. Change Manager is priced on a pay-per-use basis. You pay only for what you use. For more information, see [AWS Systems Manager Pricing](#).

## What are the primary components of Change Manager?

Change Manager components that you use to manage the change process in your organization or account include the following:

### Delegated administrator account

If you use Change Manager across an organization, you use a delegated administrator account. This is the AWS account designated as the account for managing operations activities across Systems Manager, including Change Manager. The delegated administrator account manages change activities across your organization. When you set up your organization for use with Change Manager, you specify which of your accounts serves in this role. The delegated administrator account must be the only member of the organizational unit (OU) to which it's assigned. The delegated administrator account isn't required if you use Change Manager with a single AWS account only.

#### Important

If you use Change Manager across an organization, we recommend always making changes from the delegated administrator account. Although you can make changes from other accounts in the organization, those changes won't be reported in or viewable from the delegated administrator account.

### Change template

A change template is a collection of configuration settings in Change Manager that define such things as required approvals, available runbooks, and notification options for change requests.

You can require that the change templates created by users in your organization or account go through an approval process before they can be used.

Change Manager supports two types of change templates. For an approved change request that is based on an *emergency change template*, the requested change can be made even if there are blocking events in Change Calendar. For an approved change request that is based on a *standard change template*, the requested change can't be made if there are blocking events in Change Calendar unless additional approvals are received from designated *change freeze event* approvers.

## Change request

A change request is a request in Change Manager to run an Automation runbook that updates one or more resources in your AWS or on-premises environments. A change request is created using a change template.

When you create a change request, one or more approvers in your organization or account must review and approve the request. Without the required approvals, the runbook workflow, which applies the changes you request, isn't permitted to run.

In the system, change requests are a type of OpsItem in AWS Systems Manager OpsCenter. However, OpsItems of the type `/aws/changerequest` aren't displayed in OpsCenter. As OpsItems, change requests are subject to the same enforced quotas as other types of OpsItems.

Additionally, to create a change request programmatically, you don't call the `CreateOpsItem` API operation. Instead, you use the [StartChangeRequestExecution](#) API operation. But rather than running immediately, the change request must be approved, and there must not any blocking events in Change Calendar to prevent the workflow from running. When approvals have been received and the calendar isn't blocked (or permission has been given to bypass blocking calendar events), the `StartChangeRequestExecution` action is able to complete.

## Runbook workflow

A runbook workflow is the process of requested changes being made to the targeted resources in your cloud or on-premises environment. Each change request designates a single Automation runbook to use to make the requested change. The runbook workflow occurs after all required approvals have been granted and there are no blocking events in Change Calendar. If the change has been scheduled for a specific date and time, the runbook workflow doesn't begin until scheduled, even if all approvals have been received and the calendar isn't blocked.

## Topics

- [Setting up Change Manager](#)
- [Working with Change Manager](#)
- [Auditing and logging Change Manager activity](#)
- [Troubleshooting Change Manager](#)

## Setting up Change Manager

You can use Change Manager, a capability of AWS Systems Manager, to manage changes for an entire organization, as configured in AWS Organizations, or for a single AWS account.

If you're using Change Manager with an organization, begin with the topic [Setting up Change Manager for an organization \(management account\)](#), and then proceed to [Configuring Change Manager options and best practices](#).

If you're using Change Manager with a single account, proceed directly to [Configuring Change Manager options and best practices](#).

### Note

If you begin using Change Manager with a single account, but that account is later added to an organizational unit for which Change Manager is allowed, your single account settings are disregarded.

### Topics

- [Setting up Change Manager for an organization \(management account\)](#)
- [Configuring Change Manager options and best practices](#)
- [Configuring roles and permissions for Change Manager](#)
- [Controlling access to auto-approval runbook workflows](#)

### Setting up Change Manager for an organization (management account)

The tasks in this topic apply if you're using Change Manager, a capability of AWS Systems Manager, with an organization that is set up in AWS Organizations. If you want to use Change Manager only with a single AWS account, skip to the topic [Configuring Change Manager options and best practices](#).

Perform the tasks in this section in an AWS account that is serving as the *management account* in Organizations. For information about the management account and other Organizations concepts, see [AWS Organizations terminology and concepts](#).

If you need to turn on Organizations and specify your account as the management account before proceeding, see [Creating and managing an organization](#) in the *AWS Organizations User Guide*.

**Note**

This setup process can't be performed in the following AWS Regions:

- Europe (Milan) (eu-south-1)
- Middle East (Bahrain) (me-south-1)
- Africa (Cape Town) (af-south-1)
- Asia Pacific (Hong Kong) (ap-east-1)

Ensure that you're working in a different Region in your management account for this procedure.

During the setup procedure, you perform the following major tasks in Quick Setup, a capability of AWS Systems Manager.

**• Task 1: Register the delegated administrator account for your organization**

The change-related tasks that are performed using Change Manager are managed in one of your member accounts, which you specify to be the *delegated administrator account*. The delegated administrator account you register for Change Manager becomes the delegated administrator account for all your Systems Manager operations. (You might have delegated administrator accounts for other AWS services). Your delegated administrator account for Change Manager, which isn't the same as your management account, manages change activities across your organization, including change templates, change requests, and approvals for each. In the delegated administrator account, you also specify other configuration options for your Change Manager operations.

**⚠ Important**

The delegated administrator account must be the only member of the organizational unit (OU) to which it's assigned in Organizations.

**• Task 2: Define and specify runbook access policies for change requester roles, or custom job functions, that you want to use for your Change Manager operations**

In order to create change requests in Change Manager, users in your member accounts must be granted AWS Identity and Access Management (IAM) permissions that allow them to access only the Automation runbooks and change templates you choose to make available to them.

 **Note**

When a user creates a change request, they first select a change template. This change template might make multiple runbooks available, but the user can select only one runbook for each change request. Change templates can also be configured to allow users to include any available runbook in their requests.

To grant the needed permissions, Change Manager uses the concept of *job functions*, which is also used by IAM. However, unlike the [AWS managed policies for job functions](#) in IAM, you specify both the names of your Change Manager job functions and the IAM permissions for those job functions.

When you configure a job function, we recommend creating a custom policy and providing only the permissions needed to perform change management tasks. For instance, you might specify permissions that limit users to that specific set of runbooks based on *job functions* that you define.

For example, you might create a job function with the name DBAdmin. For this job function, you might grant only permissions needed for runbooks related to Amazon DynamoDB databases, such as `AWS-CreateDynamoDbBackup` and `AWSConfigRemediation-DeleteDynamoDbTable`.

As another example, you might want to grant some users only the permissions needed to work with runbooks related to Amazon Simple Storage Service (Amazon S3) buckets, such as `AWS-ConfigureS3BucketLogging` and `AWSConfigRemediation-ConfigureS3BucketPublicAccessBlock`.

The configuration process in Quick Setup for Change Manager also makes a set of full Systems Manager administrative permissions available for you to apply to an administrative role you create.

Each Change Manager Quick Setup configuration you deploy creates a job function in your delegated administrator account with permissions to run Change Manager templates and

Automation runbooks in the organizational units you have selected. You can create up to 15 Quick Setup configurations for Change Manager.

- **Task 3: Choose which member accounts in your organization to use with Change Manager**

You can use Change Manager with all the member accounts in all your organizational units that are set up in Organizations, and in all the AWS Regions they operate in. If you prefer, you can instead use Change Manager with only some of your organizational units.

### **Important**

We strongly recommend, before you begin this procedure, that you read through its steps to understand the configuration choices you're making and the permissions you're granting. In particular, plan the custom job functions you will create and the permissions you assign to each job function. This ensures that when later you attach the job function policies you create to individual users, user groups, or IAM roles, they're being granted only the permissions you intend for them to have.

As a best practice, begin by setting up the delegated administrator account using the login for an AWS account administrator. Then configure job functions and their permissions after you have created change templates and identified the runbooks that each one uses.

To set up Change Manager for use with an organization, perform the following task in the Quick Setup area of the Systems Manager console.

You repeat this task for each job function you want to create for your organization. Each job function you create can have permissions for a different set of organizational units.

### **To set up an organization for Change Manager in the Organizations management account**

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Quick Setup**.
3. On the **Change Manager** card, choose **Create**.
4. For **Delegated administrator account**, enter the ID of the AWS account you want to use for managing change templates, change requests, and runbook workflows in Change Manager.

If you have previously specified a delegated administrator account for Systems Manager, its ID is already reported in this field.

**⚠ Important**

The delegated administrator account must be the only member of the organizational unit (OU) to which it's assigned in Organizations.

If the delegated administrator account you register is later deregistered from that role, the system removes its permissions for managing Systems Manager operations at the same time. Keep in mind that it will be necessary for you return to Quick Setup, designate a different delegated administrator account, and specify all job functions and permissions again.

If you use Change Manager across an organization, we recommend always making changes from the delegated administrator account. Although you can make changes from other accounts in the organization, those changes won't be reported in or viewable from the delegated administrator account.

5. In the **Permissions to request and make changes** section, do the following.

**ℹ Note**

Each deployment configuration you create provides the permissions policy for just one job function. You can return to Quick Setup later to create more job functions when you have created change templates to use in your operations.

**To create an administrative role** – For an administrator job function that has IAM permissions for all AWS actions, do the following.

**⚠ Important**

Granting users full administrative permissions should be done sparingly, and only if their roles require full Systems Manager access. For important information about security considerations for Systems Manager access, see [Identity and access management for AWS Systems Manager](#) and [Security best practices for Systems Manager](#).

1. For **Job function**, enter a name to identify this role and its permissions, such as **MyAWSAdmin**.
2. For **Role and permissions option**, choose **Administrator permissions**.

**To create other job functions** – To create a non-administrative role, do the following:

1. For **Job function**, enter a name to identify this role and suggest its permissions. The name you choose should represent scope of the runbooks for which you will provide permissions, such as DBAdmin or S3Admin.
2. For **Role and permissions option**, choose **Custom permissions**.
3. In the **Permissions policy editor**, enter the IAM permissions, in JSON format, to grant to this job function.

 **Tip**

We recommend that you use the IAM policy editor to construct your policy and then paste the policy JSON into the **Permissions policy** field.

### **Sample policy: DynamoDB database management**

For example, you might begin with policy content that provides permissions for working with the Systems Manager documents (SSM documents) the job function needs access to. Here is a sample policy content that grants access to all the AWS managed Automation runbooks related to DynamoDB databases and two change templates that have been created in the sample AWS account 123456789012, in the US East (Ohio) Region (us-east-2).

The policy also includes permission for the [StartChangeRequestExecution](#) operation, which is required for creating a change request in Change Calendar.

 **Note**

This example isn't comprehensive. Additional permissions might be needed for working with other AWS resources, such as databases and nodes.

        "arn:aws:ssm:region:*:document/AWSConfigRemediation-DeleteDynamoDbTable",
        "arn:aws:ssm:region:*:document/AWSConfigRemediation-EnableEncryptionOnDynamoDbTable",
        "arn:aws:ssm:region:*:document/AWSConfigRemediation-EnablePITRForDynamoDbTable",
        "arn:aws:ssm:region:123456789012:document/MyFirstDBChangeTemplate",
        "arn:aws:ssm:region:123456789012:document/MySecondDBChangeTemplate"
      ]
    },
    {
      "Effect": "Allow",
      "Action": "ssm:ListDocuments",
      "Resource": "*"
    },
    {
      "Effect": "Allow",
      "Action": "ssm:StartChangeRequestExecution",
      "Resource": "arn:aws:ssm:region:123456789012:automation-definition/*:*"
    }
  ]
}

```

```
}
```

For more information about IAM policies, see [Access management for AWS resources](#) and [Creating IAM policies](#) in the *IAM User Guide*.

6. In the **Targets** section, choose whether to grant permissions for the job function you're creating to your entire organization or only some of your organizational units.

If you choose **Entire organization**, continue to step 9.

If you choose **Custom**, continue to step 8.

7. In the **Target OUs** section, select the check boxes of the organizational units to use with Change Manager.
8. Choose **Create**.

After the system finishes setting up Change Manager for your organization, it displays a summary of your deployments. This summary information includes the name of the role that was created for the job function you configured. For example, `AWS-QuickSetup-SSMChangeMgr-DBAdminInvocationRole`.

#### Note

Quick Setup uses AWS CloudFormation StackSets to deploy your configurations. You can also view information about a completed deployment configuration in the AWS CloudFormation console. For information about StackSets, see [Working with AWS CloudFormation StackSets](#) in the *AWS CloudFormation User Guide*.

Your next step is to configure additional Change Manager options. You can complete this task in either your delegated administrator account or any account in an organization unit that you have allowed for use with Change Manager. You configure options such as choosing a user identity management option, specifying which users can review and approve or reject change templates and change requests, and choosing which best practice options to allow for your organization. For information, see [Configuring Change Manager options and best practices](#).

## Configuring Change Manager options and best practices

The tasks in this section must be performed whether you're using Change Manager, a capability of AWS Systems Manager, across an organization or in a single AWS account.

If you're using Change Manager for an organization, you can perform the following tasks in either your delegated administrator account or any account in an organization unit that you have allowed for use with Change Manager.

## Topics

- [Task 1: Configuring Change Manager user identity management and template reviewers](#)
- [Task 2: Configuring Change Manager change freeze event approvers and best practices](#)
- [Configuring Amazon SNS topics for Change Manager notifications](#)

### Task 1: Configuring Change Manager user identity management and template reviewers

Perform the task in this procedure the first time you access Change Manager. You can update these configuration settings later by returning to Change Manager and choosing **Edit** on the **Settings** tab.

#### To configure Change Manager user identity management and template reviewers

1. Sign in to the AWS Management Console.

If you're using Change Manager for an organization, sign in using your credentials for your delegated administrator account. The user must have the necessary AWS Identity and Access Management (IAM) permissions for making updates to your Change Manager settings.

2. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
3. In the navigation pane, choose **Change Manager**.
4. On the service home page, depending on the available options, do one of the following:
  - If you're using Change Manager with AWS Organizations, choose **Set up delegated account**.
  - If you're using Change Manager with a single AWS account, choose **Set up Change Manager**.

-or-

Choose **Create sample change request**, **Skip**, and then choose the **Settings** tab.

5. For **User identity management**, choose one of the following.
  - **AWS Identity and Access Management (IAM)** – Identify the users who make and approve requests and perform other actions in Change Manager by using your existing user, groups, and roles.

- **AWS IAM Identity Center (IAM Identity Center)** – Allow [IAM Identity Center](#) to create and manage identities, or connect to your existing identity source to identify the users who perform actions in Change Manager.
6. In the **Template reviewer notification** section, specify the Amazon Simple Notification Service (Amazon SNS) topics to use to notify template reviewers that a new change template or change template version is ready for review. Ensure that the Amazon SNS topic you choose is configured to send notifications to your template reviewers.

For information about creating and configuring Amazon SNS topics for change template reviewer notifications, see [Configuring Amazon SNS topics for Change Manager notifications](#).

1. To specify the Amazon SNS topic for template reviewer notification, choose one of the following:
  - **Enter an SNS Amazon Resource Name (ARN)** – For **Topic ARN**, enter the ARN of an existing Amazon SNS topic. This topic can be in any of your organization's accounts.
  - **Select an existing SNS topic** – For **Target notification topic**, select the ARN of an existing Amazon SNS topic in your current AWS account. (This option isn't available if you haven't yet created any Amazon SNS topics in your current AWS account and AWS Region.)

 **Note**

The Amazon SNS topic you select must be configured to specify the notifications it sends and the subscribers they're sent to. Its access policy must also grant permissions to Systems Manager so Change Manager can send notifications. For information, see [Configuring Amazon SNS topics for Change Manager notifications](#).

2. Choose **Add notification**.
7. In the **Change template reviewers** section, select the users in your organization or account to review new change templates or change template versions before they can be used in your operations.

Change template reviewers are responsible for verifying the suitability and security of templates other users have submitted for use in Change Manager runbook workflows.

Select change template reviewers by doing the following:

1. Choose **Add**.

2. Select the check box next to the name of each user, group, or IAM role you want to assign as a change template reviewer.
  3. Choose **Add approvers**.
8. Choose **Submit**.

After you complete this initial setup process, configure additional Change Manager settings and best practices by following the steps in [Task 2: Configuring Change Manager change freeze event approvers and best practices](#).

## Task 2: Configuring Change Manager change freeze event approvers and best practices

After you complete the steps in [Task 1: Configuring Change Manager user identity management and template reviewers](#), you can designate extra reviewers for change requests during *change freeze events* and specify which available best practices you want to allow for your Change Manager operations.

A change freeze event means that restrictions are in place in the current change calendar (the calendar state in AWS Systems Manager Change Calendar is CLOSED). In these cases, in addition to regular approvers for change requests, or if the change request is created using a template that allow auto-approvals, change freeze approvers must grant permission for this change request to run. If they don't, the change won't be processed until the calendar state is again OPEN.

### To configure Change Manager change freeze event approvers and best practices

1. In the navigation pane, choose **Change Manager**.
2. Choose the **Settings** tab, and then choose **Edit**.
3. In the **Approvers for change freeze events** section, select the users in your organization or account who can approve changes to run even when the calendar in use in Change Calendar is currently CLOSED.

#### Note

To allow change freeze reviews, you must turn on the **Check Change Calendar for restricted change events** option in **Best practices**.

Select approvers for change freeze events by doing the following:

1. Choose **Add**.
2. Select the check box next to the name of each user, group, or IAM role you want to assign as an approver for change freeze events.
3. Choose **Add approvers**.
4. In the **Best practices** section near the bottom of the page, turn on the best practices you want to enforce for each of the following options.

- Option: **Check Change Calendar for restricted change events**

To specify that Change Manager checks a calendar in Change Calendar to make sure changes aren't blocked by scheduled events, first select the **Enabled** check box, and then select the calendar to check for restricted events from the **Change Calendar** list.

For more information about Change Calendar, see [AWS Systems Manager Change Calendar](#).

- Option: **SNS topic for approvers for closed events**

1. Choose one of the following to specify the Amazon Simple Notification Service (Amazon SNS) topic in your account to use for sending notifications to approvers during change freeze events. (Note that you must also specify approvers in the **Approvers for change freeze events** section above **Best practices**.)

- **Enter an SNS Amazon Resource Name (ARN)** – For **Topic ARN**, enter the ARN of an existing Amazon SNS topic. This topic can be in any of your organization's accounts.
- **Select an existing SNS topic** – For **Target notification topic**, select the ARN of an existing Amazon SNS topic in your current AWS account. (This option isn't available if you haven't yet created any Amazon SNS topics in your current AWS account and AWS Region.)

 **Note**

The Amazon SNS topic you select must be configured to specify the notifications it sends and the subscribers they're sent to. Its access policy must also grant permissions to Systems Manager so Change Manager can send notifications. For information, see [Configuring Amazon SNS topics for Change Manager notifications](#).

2. Choose **Add notification**.

- Option: **Require monitors for all templates**

If you want to ensure that all templates for your organization or account specify an Amazon CloudWatch alarm to monitor your change operation, select the **Enabled** check box.

- Option: **Require template review and approval before use**

To ensure that no change requests are created, and no runbook workflows run, without being based on a template that has been reviewed and approved, select the **Enabled** check box.

5. Choose **Save**.

## Configuring Amazon SNS topics for Change Manager notifications

You can configure Change Manager, a capability of AWS Systems Manager, to send notifications to an Amazon Simple Notification Service (Amazon SNS) topic for events related to change requests and change templates. Complete the following tasks to receive notifications for the Change Manager events you add a topic to.

### Topics

- [Task 1: Create and subscribe to an Amazon SNS topic](#)
- [Task 2: Update the Amazon SNS access policy](#)
- [Task 3: \(Optional\) Update the AWS Key Management Service access policy](#)

### Task 1: Create and subscribe to an Amazon SNS topic

First, you must create and subscribe to an Amazon SNS topic. For more information, see [Creating a Amazon SNS topic](#) and [Subscribing to an Amazon SNS topic](#) in the *Amazon Simple Notification Service Developer Guide*.

#### Note

To receive notifications, you must specify the Amazon Resource Name (ARN) of an Amazon SNS topic that is in the same AWS Region and AWS account as the delegated administrator account.

## Task 2: Update the Amazon SNS access policy

Use the following procedure to update the Amazon SNS access policy so that Systems Manager can publish Change Manager notifications to the Amazon SNS topic you created in Task 1. Without completing this task, Change Manager doesn't have permission to send notifications for the events you add the topic for.

1. Sign in to the AWS Management Console and open the Amazon SNS console at <https://console.aws.amazon.com/sns/v3/home>.
2. In the navigation pane, choose **Topics**.
3. Choose the topic you created in Task 1, and then choose **Edit**.
4. Expand **Access policy**.
5. Add and update the following Sid block to the existing policy and replace each *user input placeholder* with your own information .

```
{
  "Sid": "Allow Change Manager to publish to this topic",
  "Effect": "Allow",
  "Principal": {
    "Service": "ssm.amazonaws.com"
  },
  "Action": "sns:Publish",
  "Resource": "arn:aws:sns:region:account-id:topic-name",
  "Condition": {
    "StringEquals": {
      "aws:SourceAccount": [
        "account-id"
      ]
    }
  }
}
```

Enter this block after the existing Sid block, and replace *region*, *account-id*, and *topic-name* with the appropriate values for the topic you created.

6. Choose **Save changes**.

The system now sends notifications to the Amazon SNS topic when the event type you add to topic for occurs.

**⚠ Important**

If you configured the Amazon SNS topic with an AWS Key Management Service (AWS KMS) server-side encryption key, then you must complete Task 3.

**Task 3: (Optional) Update the AWS Key Management Service access policy**

If you turned on AWS Key Management Service (AWS KMS) server-side encryption for your Amazon SNS topic, then you must also update the access policy of the AWS KMS key you chose when you configured the topic. Use the following procedure to update the access policy so that Systems Manager can publish Change Manager approval notifications to the Amazon SNS topic you created in Task 1.

1. Open the AWS KMS console at <https://console.aws.amazon.com/kms>.
2. In the navigation pane, choose **Customer managed keys**.
3. Choose the ID of the customer managed key you chose when you created the topic.
4. In the **Key policy** section, choose **Switch to policy view**.
5. Choose **Edit**.
6. Enter the following Sid block after one of the existing Sid blocks in the existing policy. Replace each *user input placeholder* with your own information.

```
{
  "Sid": "Allow Change Manager to decrypt the key",
  "Effect": "Allow",
  "Principal": {
    "Service": "ssm.amazonaws.com"
  },
  "Action": [
    "kms:Decrypt",
    "kms:GenerateDataKey*"
  ],
  "Resource": "arn:aws:kms:region:account-id:key/key-id",
  "Condition": {
    "StringEquals": {
      "aws:SourceAccount": [
        "account-id"
      ]
    }
  }
}
```

```

    }
  }
}

```

- Now enter the following Sid block after one of the existing Sid blocks in the resource policy to help prevent the [cross-service confused deputy problem](#).

This block uses the [aws:SourceArn](#) and [aws:SourceAccount](#) global condition context keys to limit the permissions that Systems Manager gives another service to the resource.

Replace each *user input placeholder* with your own information.

```

{
  "Version": "2008-10-17",
  "Statement": [
    {
      "Sid": "Configure confused deputy protection for AWS KMS keys used in Amazon
      SNS topic when called from Systems Manager",
      "Effect": "Allow",
      "Principal": {
        "Service": "ssm.amazonaws.com"
      },
      "Action": [
        "sns:Publish"
      ],
      "Resource": "arn:aws:sns:region:account-id:topic-name",
      "Condition": {
        "ArnLike": {
          "aws:SourceArn": "arn:aws:ssm:region:account-id:*"
        },
        "StringEquals": {
          "aws:SourceAccount": "account-id"
        }
      }
    }
  ]
}

```

- Choose **Save changes**.

## Configuring roles and permissions for Change Manager

By default, Change Manager doesn't have permission to perform actions on your resources. You must grant access by using an AWS Identity and Access Management (IAM) service role, or *assume role*. This role enables Change Manager to securely run the runbook workflows specified in an approved change request on your behalf. The role grants AWS Security Token Service (AWS STS) [AssumeRole](#) trust to Change Manager.

By providing these permissions to a role to act on behalf of users in an organization, users don't need to be granted that array of permissions themselves. The actions allowed by the permissions are limited to approved operations only.

When users in your account or organization create a change request, they can select this assume role to perform the change operations.

You can create a new assume role for Change Manager or update an existing role with the needed permissions.

If you need to create a service role for Change Manager, complete the following tasks.

### Tasks

- [Task 1: Creating an assume role policy for Change Manager](#)
- [Task 2: Creating an assume role for Change Manager](#)
- [Task 3: Attaching the iam:PassRole policy to other roles](#)
- [Task 4: Adding inline policies to an assume role to invoke other AWS services](#)
- [Task 5: Configuring user access to Change Manager](#)

### Task 1: Creating an assume role policy for Change Manager

Use the following procedure to create the policy that you will attach to your Change Manager assume role.

#### To create an assume role policy for Change Manager

1. Open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **Policies**, and then choose **Create Policy**.
3. On the **Create policy** page, choose the **JSON** tab and replace the default content with the following, which you will modify for your own Change Manager operations in following steps.

**Note**

If you're creating a policy to use with a single AWS account, and not an organization with multiple accounts and AWS Regions, you can omit the first statement block. The `iam:PassRole` permission isn't required in the case of a single account using Change Manager.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "iam:PassRole",
      "Resource": "arn:aws:iam::delegated-admin-account-id:role/AWS-SystemsManager-job-functionAdministrationRole",
      "Condition": {
        "StringEquals": {
          "iam:PassedToService": "ssm.amazonaws.com"
        }
      }
    },
    {
      "Effect": "Allow",
      "Action": [
        "ssm:DescribeDocument",
        "ssm:GetDocument",
        "ssm:StartChangeRequestExecution"
      ],
      "Resource": [
        "arn:aws:ssm:region:account-id:automation-definition/template-name:  
$DEFAULT",
        "arn:aws:ssm:region::document/template-name"
      ]
    },
    {
      "Effect": "Allow",
      "Action": [
        "ssm:ListOpsItemEvents",
        "ssm:GetOpsItem",
        "ssm:ListDocuments",

```

```

        "ssm:DescribeOpsItems"
      ],
      "Resource": "*"
    }
  ]
}

```

4. For the `iam:PassRole` action, update the `Resource` value to include the ARNs of all job functions defined for your organization that you want to grant permissions to initiate runbook workflows.
5. Replace the *region*, *account-id*, *template-name*, *delegated-admin-account-id*, and *job-function* placeholders with values for your Change Manager operations.
6. For the second `Resource` statement, modify the list to include all change templates that you want to grant permissions for. Alternatively, specify `"Resource": "*"` to grant permissions for all change templates in your organization.
7. Choose **Next: Tags**.
8. (Optional) Add one or more tag-key value pairs to organize, track, or control access for this policy.
9. Choose **Next: Review**.
10. On the **Review policy** page, enter a name in the **Name** box, such as **MyChangeManagerAssumeRole**, and then enter an optional description.
11. Choose **Create policy**, and continue to [Task 2: Creating an assume role for Change Manager](#).

## Task 2: Creating an assume role for Change Manager

Use the following procedure to create a Change Manager assume role, a type of service role, for Change Manager.

### To create an assume role for Change Manager

1. Open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **Roles**, and then choose **Create role**.
3. For **Select trusted entity**, make the following choices:
  1. For **Trusted entity type**, choose **AWS service**
  2. For **Use cases for other AWS services**, choose **Systems Manager**
  3. Choose **Systems Manager**, as shown in the following image.

## Service or use case

Systems Manager

Choose a use case for the specified service.

## Use case

 Systems Manager

Allows SSM to call AWS services on your behalf

 Systems Manager - Inventory and Maintenance Windows

Allow AWS Systems Manager to call AWS resources on your behalf.

4. Choose **Next**.
5. On the **Attached permissions policy** page, search for the assume role policy you created in [Task 1: Creating an assume role policy for Change Manager](#), such as **MyChangeManagerAssumeRole**.
6. Select the check box next to the assume role policy name, and then choose **Next: Tags**.
7. For **Role name**, enter a name for your new instance profile, such as **MyChangeManagerAssumeRole**.
8. (Optional) For **Description**, update the description for this instance role.
9. (Optional) Add one or more tag-key value pairs to organize, track, or control access for this role.
10. Choose **Next: Review**.
11. (Optional) For **Tags**, add one or more tag-key value pairs to organize, track, or control access for this role, and then choose **Create role**. The system returns you to the **Roles** page.
12. Choose **Create role**. The system returns you to the **Roles** page.
13. On the **Roles** page, choose the role you just created to open the **Summary** page.

### Task 3: Attaching the `iam:PassRole` policy to other roles

Use the following procedure to attach the `iam:PassRole` policy to an IAM instance profile or IAM service role. (The Systems Manager service uses IAM instance profiles to communicate with EC2 instances. For non-EC2 managed nodes in a [hybrid and multicloud](#) environment, an IAM service role is used instead.)

By attaching the `iam:PassRole` policy, the Change Manager service can pass assume role permissions to other services or Systems Manager capabilities when running runbook workflows.

## To attach the `iam:PassRole` policy to an IAM instance profile or service role

1. Open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **Roles**.
3. Search for the Change Manager assume role you created, such as **MyChangeManagerAssumeRole**, and choose its name.
4. In the **Summary** page for the assume role, choose the **Permissions** tab.
5. Choose **Add permissions, Create inline policy**.
6. On the **Create policy** page, choose the **Visual editor** tab.
7. Choose **Service**, and then choose **IAM**.
8. In the **Filter actions** text box, enter **PassRole**, and then choose the **PassRole** option.
9. Expand **Resources**. Verify that **Specific** is selected, and then choose **Add ARN**.
10. In the **Specify ARN for role** field, enter the ARN of the IAM instance profile role or IAM service role to which you want to pass assume role permissions. The system populates the **Account** and **Role name with path** fields.
11. Choose **Add**.
12. Choose **Review policy**.
13. For **Name**, enter a name to identify this policy, and then choose **Create policy**.

### More info

- [Configure instance permissions required for Systems Manager](#)
- [Create the IAM service role required for Systems Manager in hybrid and multicloud environments](#)

## Task 4: Adding inline policies to an assume role to invoke other AWS services

When a change request invokes other AWS services by using the Change Manager assume role, the assume role must be configured with permission to invoke those services. This requirement applies to all AWS Automation runbooks (AWS-\* runbooks) that might be used in a change request, such as the `AWS-ConfigureS3BucketLogging`, `AWS-CreateDynamoDBBackup`, and `AWS-RestartEC2Instance` runbooks. This requirement also applies to any custom runbooks you create that invoke other AWS services by using actions that call other services. For example, if you use the `aws:executeAwsApi`, `aws:CreateStack`, or `aws:copyImage` actions, then you must

configure the service role with permission to invoke those services. You can enable permissions to other AWS services by adding an IAM inline policy to the role.

### To add an inline policy to an assume role to invoke other AWS services (IAM console)

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **Roles**.
3. In the list, choose the name of the assume role that you want to update, such as `MyChangeManagerAssumeRole`.
4. Choose the **Permissions** tab.
5. Choose **Add permissions, Create inline policy**.
6. Choose the **JSON** tab.
7. Enter a JSON policy document for the AWS services you want to invoke. Here are two example JSON policy documents.

#### Amazon S3 PutObject and GetObject example

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "s3:PutObject",
        "s3:GetObject"
      ],
      "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/*"
    }
  ]
}
```

#### Amazon EC2 CreateSnapshot and DescribeSnapshots example

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
```

```
    "Effect": "Allow",
    "Action": "ec2:CreateSnapshot",
    "Resource": "*"
  },
  {
    "Effect": "Allow",
    "Action": "ec2:DescribeSnapshots",
    "Resource": "*"
  }
]
```

For details about the IAM policy language, see [IAM JSON policy reference](#) in the *IAM User Guide*.

8. When you're finished, choose **Review policy**. The [Policy Validator](#) reports any syntax errors.
9. For **Name**, enter a name to identify the policy that you're creating. Review the policy **Summary** to see the permissions that are granted by your policy. Then choose **Create policy** to save your work.
10. After you create an inline policy, it's automatically embedded in your role.

## Task 5: Configuring user access to Change Manager

If your user, group, or role is assigned administrator permissions, then you have access to Change Manager. If you don't have administrator permissions, then an administrator must assign the AmazonSSMFullAccess managed policy, or a policy that provides comparable permissions, to your user, group, or role.

Use the following procedure to configure a user to use Change Manager. The user you choose will have permission to configure and run Change Manager.

Depending on the identity application that you are using in your organization, you can select any of the three options available to configure user access. While configuring the user access, assign or add the following:

1. Assign the AmazonSSMFullAccess policy or a comparable policy that gives permission to access Systems Manager.
2. Assign the `iam:PassRole` policy.
3. Add the ARN for the Change Manager assume role you copied at the end of [Task 2: Creating an assume role for Change Manager](#).

To provide access, add permissions to your users, groups, or roles:

- Users and groups in AWS IAM Identity Center:

Create a permission set. Follow the instructions in [Create a permission set](#) in the *AWS IAM Identity Center User Guide*.

- Users managed in IAM through an identity provider:

Create a role for identity federation. Follow the instructions in [Create a role for a third-party identity provider \(federation\)](#) in the *IAM User Guide*.

- IAM users:

- Create a role that your user can assume. Follow the instructions in [Create a role for an IAM user](#) in the *IAM User Guide*.
- (Not recommended) Attach a policy directly to a user or add a user to a user group. Follow the instructions in [Adding permissions to a user \(console\)](#) in the *IAM User Guide*.

You have finished configuring the required roles for Change Manager. You can now use the Change Manager assume role ARN in your Change Manager operations.

### Controlling access to auto-approval runbook workflows

In each change template created for your organization or account, you can specify whether change requests created from that template can run as auto-approved change requests, meaning that they run automatically without a review step (with the exception of change freeze events).

However, you might want to prevent certain users, groups, or AWS Identity and Access Management (IAM) roles from running auto-approved change requests even if a change template allows it. You can do this through the use of the `ssm:AutoApprove` condition key for the `StartChangeRequestExecution` operation in an IAM policy assigned to the user, group, or IAM role.

You can add the following policy as an inline policy, where the condition is specified as `false`, to prevent users from running auto-approvable change requests.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
```

```
    "Effect": "Allow",
    "Action": "ssm:StartChangeRequestExecution",
    "Resource": "*",
    "Condition": {
      "BoolIfExists": {
        "ssm:AutoApprove": "false"
      }
    }
  ]
}
```

For information about specifying inline policies, see [Inline policies](#) and [Adding and removing IAM identity permissions](#) in the *IAM User Guide*.

For more information about condition keys for Systems Manager policies, see [Condition keys for Systems Manager](#).

## Working with Change Manager

With Change Manager, a capability of AWS Systems Manager, users across your organization or in a single AWS account can perform change-related tasks for which they have been granted the necessary permissions. Change Manager tasks include the following:

- Create, review, and approve or reject change templates.

A change template is a collection of configuration settings in Change Manager that define such things as required approvals, available runbooks, and notification options for change requests.

- Create, review, and approve or reject change requests.

A change request is a request in Change Manager to run an Automation runbook that updates one or more resources in your AWS or on-premises environments. A change request is created using a change template.

- Specify which users in your organization or account can be made reviewers for change templates and change requests.
- Edit configuration settings, such as how user identities are managed in Change Manager and which of the available *best practice* options are enforced in your Change Manager operations. For information about configuring these settings, see [Configuring Change Manager options and best practices](#).

## Topics

- [Working with change requests](#)
- [Reviewing change request details, tasks, and timelines \(console\)](#)
- [Viewing aggregated counts of change requests \(command line\)](#)

## Working with change templates

A change template is a collection of configuration settings in Change Manager that define such things as required approvals, available runbooks, and notification options for change requests.

### Note

AWS provides a sample [Hello World](#) change template you can use to try out Change Manager, a capability of AWS Systems Manager. However, you create your own change templates to define the changes you want to allow to the resources in your organization or account.

The changes that are made when a runbook workflow runs are based on the contents an Automation runbook. In each change template you create, you can include one or more Automation runbooks that the user making a change request can choose from to run during the update. You can also create change templates that allow requesters to choose any available Automation runbook for the change request.

To create a change template, you can use the **Builder** option in the **Create template** console page to build a change template. Alternatively, using the **Editor** option, you can manually author JSON or YAML content with the configuration you want for your runbook workflow. You can also use a command line tool to create a change template, with JSON content for the change template stored in an external file.

## Topics

## Try out the AWS managed Hello World change template

You can use the sample change template `AWS-HelloWorldChangeTemplate`, which uses the sample Automation runbook `AWS-HelloWorld`, to test the review and approval process after you have finished setting up Change Manager, a capability of AWS Systems Manager. This template is designed for testing or verifying your configured permissions, approver assignments, and approval process. Approval to use this change template in your organization or account has already been provided by AWS. Any change request based on this change template, however, must still be approved by reviewers in your organization or account.

Rather than make changes to a resource, the result of the runbook workflow associated with this template is to print a message in the output of an Automation step.

### Before you begin

Before you begin, ensure you have completed the following tasks:

- If you're using AWS Organizations to manage change across an organization, complete the organization setup tasks described in [Setting up Change Manager for an organization \(management account\)](#).
- Configure Change Manager for your delegated administrator account or single account, as described in [Configuring Change Manager options and best practices](#).

#### Note

If you turned on the best practice option **Require monitors for all templates** in your Change Manager settings, turn it off temporarily while you test the Hello World change template.

## To try out the AWS managed Hello World change template

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Change Manager**.
3. Choose **Create request**.
4. Choose the change template named `AWS-HelloWorldChangeTemplate`, and then choose **Next**.

5. For **Name**, enter a name for the change request that makes its purpose easy to identify, such as **MyChangeRequestTest**.
6. For the remainder of the steps to create your change request, see [Creating change requests](#).

## Next steps

For information about approving change requests, see [Reviewing and approving or rejecting change requests](#).

To view the status and results of your change request, choose the name of your change request on the **Requests** tab in Change Manager.

## Creating change templates

A change template is a collection of configuration settings in Change Manager that define such things as required approvals, available runbooks, and notification options for change requests.

You can create change templates for your operations in Change Manager, a capability of AWS Systems Manager, using the console, which includes Builder and Editor options, or command line tools.

## Topics

- [About approvals in your change templates](#)
- [Creating change templates using Builder](#)
- [Creating change templates using Editor](#)
- [Creating change templates using command line tools](#)

## About approvals in your change templates

For each change template that you create, you can specify up to five approval *levels* for change requests created from it. For each of those levels, you can designate up to five potential *approvers*. An approver isn't limited to a single user. You can also specify an IAM group or IAM role as an individual approver. For IAM groups and IAM roles, one or more users belonging to the group or role can provide approvals toward receiving the total number of approvals required for a change request. You can also specify more approvers than your change template requires.

Change Manager supports two main approaches to approvals: *per-level approvals* and *per-line approvals*. A combination of the two types is also possible in some situations. We recommend using only per-level approvals in your Change Manager operations.

### Per-level approvals

*Recommended.* As of January 23, 2023, Change Manager supports per-level approvals. In this model, for each approval level in your change template, you first specify how many approvals are required for that level. Then you specify at least that many approvers for the level and can specify more approvers. However, only the number of per-level approvers that you specify need to approve the change request. For example, you could specify five approvers but require three approvals.

For console-view and JSON samples of this approval type, see [the section called “Sample per-level approval configuration”](#).

### Per-line approvals

*Supported for backward compatibility.* The original release of Change Manager supported only per-line approvals. In this model, every approver specified for an approval level is represented as an approval line. Each approver had to approve a change request for it to be approved at that level. Prior to January 23, 2023, this was the only supported model for approvals. Change templates created before this date continue to support per-line approvals, but we recommend using per-level approvals instead.

For console-view and JSON samples of this approval type, see [the section called “Sample per-line approval configuration”](#).

### Combined per-line and per-level approvals

*Not recommended.* In the console, the **Builder** tab no longer supports adding per-line approvals. However, in some cases you might end up with both per-line and per-level approvals in a change template. This can occur if you update a change template that was created before January 23, 2023, or if you create or update a change template by editing its YAML content manually,

For console-view and JSON samples of this approval type, see [the section called “Sample combined per-level and per-line approval configuration”](#).

**⚠ Important**

Although it's possible to create a change template that combines per-line and per-level approvals, this configuration isn't recommended or necessary. Whichever approval type requires more approvals (per-line or per-level approvals) takes precedence. For example:

- If a change template specifies three per-level approvals but five per-line approvals, then five approvals are required.
- If a change template specifies four per-level approvals but two per-line approvals, then four approvals are required.

You can create a level that includes both per-line and per-level approvals by editing the YAML or JSON content manually. Then, the **Builder** tab displays controls for specifying the required number of approvals for both the level and for individual lines. However, new levels that you add using the console still support only per-level approval configurations.

## Change request notifications and rejections

### Amazon SNS notifications

When a change request is created using your change template, notifications are sent to subscribers of the Amazon Simple Notification Service (Amazon SNS) topic that has been designated for approval notifications at that level. You can specify the notification topic in the change template or allow the user creating the change request to specify one.

After the minimum number of required approvals is received at one level, notifications are sent to approvers subscribed to the Amazon SNS topic for the next level, and so on.

**⚠ Important**

Ensure that the IAM roles, groups, and users you designate together provide enough approvers to meet the required number of approvals you specify. For example, if you designate only a single IAM group as an approver that contains three users, you can't specify that five approvals are mandatory at that level, only three or less.

## Change request rejections

No matter how many approval levels and approvers you specify, only one rejection to a change request is required to prevent the runbook workflow for that request from occurring.

## Change Manager approval type examples

The following samples demonstrate the console view and JSON content for the three types of approval types in Change Manager.

### Topics

- [Sample per-level approval configuration](#)
- [Sample per-line approval configuration](#)
- [Sample combined per-level and per-line approval configuration](#)

## Sample per-level approval configuration

In the per-level approval level setup shown in the following image, three approvals are required. Those approvals can come from any combination of IAM users, groups, and roles that are specified as approvers. Specified approvers include two IAM users (John Stiles and Ana Carolina Silva), a user group that contains three members (GroupOfThree), and a user role that represents ten users (RoleOfTen).

If all three users in the GroupOfThree group approve the change request, it is approved for that level. It's not necessary to receive an approval from each user, group, or role. The minimum number of approvals can come from any combination of specified approvers. We recommend per-level approvals for your Change Manager operations.

### First-level approvals Remove level

Number of approvals required at this level

3 ▼

| Approver           | Type      |        |
|--------------------|-----------|--------|
| John Stiles        | IAM User  | Remove |
| Ana Carolina Silva | IAM User  | Remove |
| GroupOfThree       | IAM Group | Remove |
| RoleOfTen          | IAM Role  | Remove |

Add approver ▼

The following sample illustrates part of the YAML code for this configuration.

#### Note

This version of the YAML code include an additional input, `MinRequiredApprovals` (with an initial capital M). The value for this input indicates how many approvals are required from among all available reviewers. Note also that the `minRequiredApprovals` (lowercase initial m) value for each approver in the `Approvers` list is 0 (zero). This indicates that the approver can contribute to the overall approvals but is not required to do so.

```

schemaVersion: "0.3"
emergencyChange: false
autoApprovable: false
mainSteps:
  - name: ApproveAction1
    action: aws:approve
    timeoutSeconds: 604800
    inputs:
      Message: Please approve this change request
      MinRequiredApprovals: 3

```

```

EnhancedApprovals:
  Approvers:
    - approver: John Stiles
      type: IamUser
      minRequiredApprovals: 0
    - approver: Ana Carolina Silva
      type: IamUser
      minRequiredApprovals: 0
    - approver: GroupOfThree
      type: IamGroup
      minRequiredApprovals: 0
    - approver: RoleOfTen
      type: IamRole
      minRequiredApprovals: 0
templateInformation: >
  ##### What is the purpose of this change?
  //truncated

```

## Sample per-line approval configuration

In the approval level setup shown in the following image, four approvers are specified. These include two IAM users (John Stiles and Ana Carolina Silva), a user group that contains three members (GroupOfThree), and a user role that represents ten users (RoleOfTen). Per-line approvals are supported for backwards compatibility but not recommended.

First-level approvals
Remove level

| Approver  | Type                                   | Required                         |                                       |
|---|--|----------------------------------|---------------------------------------|
| <input type="text" value="John Stiles"/>        | <input type="text" value="IAM User"/>  | <input type="text" value="1"/> ▼ | <input type="button" value="Remove"/> |
| <input type="text" value="Ana Carolina Silva"/> | <input type="text" value="IAM User"/>  | <input type="text" value="1"/> ▼ | <input type="button" value="Remove"/> |
| <input type="text" value="GroupOfThree"/>       | <input type="text" value="IAM Group"/> | <input type="text" value="1"/> ▼ | <input type="button" value="Remove"/> |
| <input type="text" value="RoleOfTen"/>          | <input type="text" value="IAM Role"/>  | <input type="text" value="1"/> ▼ | <input type="button" value="Remove"/> |

For the change request to be approved in this per-line approval configuration, it must be approved by all approver lines: John Stiles, Ana Carolina Silva, one member of the GroupOfThree group, and one member of the RoleOfTen role.

The following sample illustrates part of the YAML code for this configuration.

**Note**

Observe that the value for each `minRequiredApprovals` approver is 1. This indicates that one approval is required from each approver.

```

schemaVersion: "0.3"
emergencyChange: false
autoApprovable: false
mainSteps:
  - name: ApproveAction1
    action: aws:approve
    timeoutSeconds: 10000
    inputs:
      Message: Please approve this change request
      EnhancedApprovals:
        Approvers:
          - approver: John Stiles
            type: IamUser
            minRequiredApprovals: 1
          - approver: Ana Carolina Silva
            type: IamUser
            minRequiredApprovals: 1
          - approver: GroupOfThree
            type: IamGroup
            minRequiredApprovals: 1
          - approver: RoleOfTen
            type: IamRole
            minRequiredApprovals: 1
executableRunBooks:
  - name: AWS-HelloWorld
    version: $DEFAULT
templateInformation: >
  #### What is the purpose of this change?
  //truncated

```

### Sample combined per-level and per-line approval configuration

In the combined per-level and per-line approval setup shown in the following image, three approvals are specified for the level, but four approvals are specified for the line-item approvals. Whichever approval type requires more approvals takes precedence over the other, so four

approvals are required by this configuration. Combined per-level and per-line approval are not recommended.

**First-level approvals** Remove level

Number of approvals required at this level

| Approver  | Type   | Required   |   |
|---|--|--|---|
| <input style="width: 150px;" type="text" value="John Stiles"/>        | <input style="width: 150px;" type="text" value="IAM User"/>  | <input style="width: 100px;" type="text" value="1"/> | <input style="border: 1px solid #ccc; padding: 2px 5px;" type="button" value="Remove"/> |
| <input style="width: 150px;" type="text" value="Ana Carolina Silva"/> | <input style="width: 150px;" type="text" value="IAM User"/>  | <input style="width: 100px;" type="text" value="1"/> | <input style="border: 1px solid #ccc; padding: 2px 5px;" type="button" value="Remove"/> |
| <input style="width: 150px;" type="text" value="GroupOfThree"/>       | <input style="width: 150px;" type="text" value="IAM Group"/> | <input style="width: 100px;" type="text" value="1"/> | <input style="border: 1px solid #ccc; padding: 2px 5px;" type="button" value="Remove"/> |
| <input style="width: 150px;" type="text" value="RoleOfTen"/>          | <input style="width: 150px;" type="text" value="IAM Role"/>  | <input style="width: 100px;" type="text" value="1"/> | <input style="border: 1px solid #ccc; padding: 2px 5px;" type="button" value="Remove"/> |

## Topics

- [Creating change templates using Builder](#)
- [Creating change templates using Editor](#)
- [Creating change templates using command line tools](#)

## Creating change templates using Builder

Using the Builder for change templates in Change Manager, a capability of AWS Systems Manager, you can configure the runbook workflow defined in your change template without having to use JSON or YAML syntax. After you specify your options, the system converts your input into the YAML format that Systems Manager can use to run runbook workflows.

### To create a change template using Builder

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Change Manager**.
3. Choose **Create template**.
4. For **Name**, enter a name for the template that makes its purpose easy to identify, such as **UpdateEC2LinuxAMI**.
5. In the **Change template details** section, do the following:
  - For **Description**, provide a brief explanation of how and when the change template you're creating is to be used.

This description helps users who create change requests determine whether they're using the correct change template. It helps those who review change requests understand whether the request should be approved.

- For **Change template type**, specify whether you're creating a standard change template or an emergency change template.

An emergency change template is used for situations when a change must be made even if changes are otherwise blocked by an event in the calendar in use by AWS Systems Manager Change Calendar. Change requests created from an emergency change template must still

be approved by its designated approvers, but the requested changes can still run even when the calendar is blocked.

- For **Runbook options**, specify the runbooks that users can choose from when creating a change request. You can add a single runbook or multiple runbooks. Alternatively, you can allow requesters to specify which runbook to use. In any of these cases, only one runbook can be included in the change request.
- For **Runbook**, select the names of the runbooks and the versions of those runbooks that users can choose from for their change requests. No matter how many runbooks you add to the change template, only one can be selected per change request.

You don't specify a runbook if you chose **Any runbook can be used** earlier.

**Tip**

Select a runbook and runbook version, and then choose **View** to examine the contents of the runbook in the Systems Manager Documents interface.

6. In the **Template information** section, use Markdown to enter information for users who create change requests from this change template. We have provided a set of questions that you can include for users who create change requests, or you can add other information and questions instead.

**Note**

Markdown is a markup language that allows you to add wiki-style descriptions to documents and individual steps within the document. For more information about using Markdown, see [Using Markdown in AWS](#).

We recommend providing questions for users to answer about their change requests to help approvers decide whether or not to grant each change request, such as listing any manual steps required to run as part of the change and a rollback plan.

**Tip**

Toggle between **Hide preview** and **Show preview** to see what your content looks like as you compose.

## 7. In the **Change request approvals** section, do the following:

- (Optional) If you want to allow change requests that are created from this change template to run automatically, without review by any approvers (with the exception of change freeze events), select **Enable auto-approval**.

### **Note**

Enabling auto-approvals in a change template provides users with the *option* of bypassing reviewers. They can still choose to specify reviewers when creating a change request. Therefore, you must still specify reviewer options in the change template.

### **Important**

If you enable auto-approval for a change template, users can submit change requests using that template that do not require review by reviewers before they run (with the exception of change freeze event approvers). If you want to restrict a particular user, group, or IAM role from submitting auto-approval requests, you can use a condition in an IAM policy for this purpose. For more information, see [Controlling access to auto-approval runbook workflows](#).

- For **Number of approvals required at this level**, choose the number of approvals that change requests created from this change template must receive for this level.
- To add mandatory first-level approvers, choose **Add approver**, and then choose from the following:
  - **Template specified approvers** – Choose one or more users, groups, or AWS Identity and Access Management (IAM) roles from your account to approve change requests created from this change template. Any change requests that are created using this template must be reviewed and approved by each approver you specify.
  - **Request specified approvers** – The user who makes the change request specifies reviewers at the time they make the request and can choose from a list of users in your account.

The number you enter in the **Required** column determines how many reviewers must be specified by a change request that uses this change template.

**⚠ Important**

Prior to January 23, 2023, the **Builder** tab supported specifying per-line approvals only. New change templates and new levels you add to existing change templates using the **Builder** tab support per-level approvals only. We recommend using only per-level approvals in your Change Manager operations.

For more information, see [About approvals in your change templates](#).

- For **SNS topic to notify approvers**, do the following:
  1. Choose one of the following to specify the Amazon Simple Notification Service (Amazon SNS) topic in your account to use for sending notifications to approvers that a change request is ready for their review:
    - **Enter an SNS Amazon Resource Name (ARN)** – For **Topic ARN**, enter the ARN of an existing Amazon SNS topic. This topic can be in any of your organization's accounts.
    - **Select an existing SNS topic** – For **Target notification topic**, select the ARN of an existing Amazon SNS topic in your current AWS account. (This option isn't available if you haven't yet created any Amazon SNS topics in your current AWS account and AWS Region.)
    - **Specify SNS topic when the change request is created** – The user who creates a change request can specify the Amazon SNS topic to use for notifications.

**ℹ Note**

The Amazon SNS topic you select must be configured to specify the notifications it sends and the subscribers they're sent to. Its access policy must also grant permissions to Systems Manager so Change Manager can send notifications. For information, see [Configuring Amazon SNS topics for Change Manager notifications](#).

2. Choose **Add notification**.
8. (Optional) To add an additional level of approvers, choose **Add approval level** and choose between template-specified approvers and request-specified approvers for this level. Then choose an SNS topic to notify this level of approvers.

After all approvals have been received by first-level approvers, second-level approvers are notified, and so on.

You can add a maximum of five levels of approvers in each template. You might, for example, require approvals from users in technical roles for the first level, then managerial approval for the second level.

9. In the **Monitoring** section, for **CloudWatch alarm to monitor**, enter the name of an Amazon CloudWatch alarm in the current account to monitor the progress of runbook workflows that are based on this template.

**Tip**

To create a new alarm, or to review the settings of an alarm you want to specify, choose **Open the Amazon CloudWatch console**. For information about working with CloudWatch alarms, see [Using CloudWatch Alarms](#) in the *Amazon CloudWatch User Guide*.

10. In the **Notifications** section, do the following:
  1. Choose one of the following to specify the Amazon SNS topic in your account to use for sending notifications about change requests that are created using this change template:
    - **Enter an SNS Amazon Resource Name (ARN)** – For **Topic ARN**, enter the ARN of an existing Amazon SNS topic. This topic can be in any of your organization's accounts.
    - **Select an existing SNS topic** – For **Target notification topic**, select the ARN of an existing Amazon SNS topic in your current AWS account. (This option isn't available if you haven't yet created any Amazon SNS topics in your current AWS account and AWS Region.)

**Note**

The Amazon SNS topic you select must be configured to specify the notifications it sends and the subscribers they're sent to. Its access policy must also grant permissions to Systems Manager so Change Manager can send notifications. For information, see [Configuring Amazon SNS topics for Change Manager notifications](#).

2. Choose **Add notification**.
11. (Optional) In the **Tags** section, apply one or more tag key name/value pairs to the change template.

Tags are optional metadata that you assign to a resource. By using tags, you can categorize a resource in different ways, such as by purpose, owner, or environment. For example, you might

want to tag a change template to identify the type of change it makes and the environment it runs in. In this case, you could specify the following key name/value pairs:

- Key=TaskType, Value=InstanceRepair
- Key=Environment, Value=Production

12. Choose **Save and preview**.

13. Review the details of the change template you're creating.

If you want to make change to the change template before submitting it for review, choose **Actions, Edit**.

If you're satisfied with the contents of the change template, choose **Submit for review**. The users in your organization or account who have been specified as template reviewers on the **Settings** tab in Change Manager are notified that a new change template is pending their review.

If an Amazon SNS topic has been specified for change templates, notifications are sent when the change template is rejected or approved. If you don't receive notifications related to this change template, you can return to Change Manager later to check on its status.

## Creating change templates using Editor

Use the steps in this topic to configure a change template in Change Manager, a capability of AWS Systems Manager, by entering JSON or YAML instead of using the console controls.

### To create a change template using Editor

1. In the navigation pane, choose **Change Manager**.
2. Choose **Create template**.
3. For **Name**, enter a name for the template that makes its purpose easy to identify, such as **RestartEC2LinuxInstance**.
4. Above **Change template details**, choose **Editor**.
5. In the **Document editor** section, choose **Edit**, and then enter the JSON or YAML content for your change template.

The following is an example.

**Note**

The parameter `minRequiredApprovals` is used to specify how many reviewers at a specified level must approve a change request that is created using this template. This example demonstrates two levels of approvals. You can specify up to five levels of approvals, but only one level is required.

In the first level, the specific user "John-Doe" must approve each change request. After that, any three members of the IAM role `Admin` must approve the change request.

For more information about approvals for change templates, see [About approvals in your change templates](#).

**YAML**

## What does this document do?\n
This change template demonstrates the feature set available for creating
change templates for Change Manager.
This template starts a Runbook workflow for the Automation runbook called
AWS-HelloWorld.\n\n
## Input Parameters\n* ApproverSnsTopicArn: (Required) Amazon Simple
Notification Service ARN for approvers.\n
* Approver: (Required) The name of the approver to send this request to.\n
* ApproverType: (Required) The type of reviewer. * Allowed Values: IamUser,
IamGroup, IamRole, SSOGroup, SSOUser\n\n
## Output Parameters\nThis document has no outputs\n",
  "schemaVersion": "0.3",
  "parameters": {
    "ApproverSnsTopicArn": {
      "type": "String",
      "description": "Amazon Simple Notification Service ARN for approvers."
    },
    "Approver": {
      "type": "String",
      "description": "IAM approver"
    },
    "ApproverType": {
      "type": "String",
      "description": "Approver types for the request. Allowed values include
IamUser, IamGroup, IamRole, SSOGroup, and SSOUser."
    }
  },
  "executableRunBooks": [
    {
      "name": "AWS-HelloWorld",
      "version": "1"
    }
  ],
}
```

```
"emergencyChange": false,

    "inputs": {
      "Message": "A sample change request has been submitted for your
review in Change Manager. You can approve or reject this request.",
      "EnhancedApprovals": {
        "NotificationArn": "{{ ApproverSnsTopicArn }}",
        "Approvers": [
          {
            "approver": "Admin",
            "type": "IamRole",
            "minRequiredApprovals": 3
          }
        ]
      }
    }
  }
]
}
```

6. Choose **Save and preview**.
7. Review the details of the change template you're creating.

If you want to make change to the change template before submitting it for review, choose **Actions, Edit**.

If you're satisfied with the contents of the change template, choose **Submit for review**. The users in your organization or account who have been specified as template reviewers on the **Settings** tab in Change Manager are notified that a new change template is pending their review.

If an Amazon Simple Notification Service (Amazon SNS) topic has been specified for change templates, notifications are sent when the change template is rejected or approved. If you don't receive notifications related to this change template, you can return to Change Manager later to check on its status.

## Creating change templates using command line tools

The following procedures describe how to use the AWS Command Line Interface (AWS CLI) (on Linux, macOS, or Windows) or AWS Tools for Windows PowerShell to create a change request in Change Manager, a capability of AWS Systems Manager.

### To create a change template

1. Install and configure the AWS CLI or the AWS Tools for PowerShell, if you haven't already.

For information, see [Installing or updating the latest version of the AWS CLI](#) and [Installing the AWS Tools for PowerShell](#).

2. Create a JSON file on your local machine with a name such as `MyChangeTemplate.json`, and then paste the content for your change template into it.

#### **Note**

Change templates use a version of schema 0.3 that doesn't include all the same support as for Automation runbooks.

The following is an example.

**Note**

The parameter `minRequiredApprovals` is used to specify how many reviewers at a specified level must approve a change request that is created using this template. This example demonstrates two levels of approvals. You can specify up to five levels of approvals, but only one level is required.

In the first level, the specific user "John-Doe" must approve each change request. After that, any three members of the IAM role `Admin` must approve the change request.

For more information about approvals for change templates, see [About approvals in your change templates](#).

```
{

    {
        "name": "ApproveAction1",
        "action": "aws:approve",
        "timeoutSeconds": 3600,
        "inputs": {
            "Message": "A sample change request has been submitted for your review
in Change Manager. You can approve or reject this request.",
            "EnhancedApprovals": {
                "NotificationArn": "{{ ApproverSnsTopicArn }}",
                "Approvers": [
                    {
                        "approver": "John-Doe",
                        "type": "IamUser",
                        "minRequiredApprovals": 1
                    }
                ]
            }
        }
    },
    {
        "name": "ApproveAction2",
        "action": "aws:approve",
        "timeoutSeconds": 3600,
        "inputs": {
            "Message": "A sample change request has been submitted for your review
in Change Manager. You can approve or reject this request.",
            "EnhancedApprovals": {
                "NotificationArn": "{{ ApproverSnsTopicArn }}",
                "Approvers": [
                    {

```

```

        "approver": "Admin",
        "type": "IamRole",
        "minRequiredApprovals": 3
      }
    ]
  }
}

```

3. Run the following command to create the change template.

### Linux & macOS

```

aws ssm create-document \
  --name MyChangeTemplate \
  --document-format JSON \
  --document-type Automation.ChangeTemplate \
  --content file://MyChangeTemplate.json \
  --tags Key=tag-key,Value=tag-value

```

### Windows

```

aws ssm create-document ^
  --name MyChangeTemplate ^
  --document-format JSON ^
  --document-type Automation.ChangeTemplate ^
  --content file://MyChangeTemplate.json ^
  --tags Key=tag-key,Value=tag-value

```

### PowerShell

```

$json = Get-Content -Path "C:\path\to\file\MyChangeTemplate.json" | Out-String
New-SSMDocument `
  -Content $json `
  -Name "MyChangeTemplate" `
  -DocumentType "Automation.ChangeTemplate" `
  -Tags "Key=tag-key,Value=tag-value"

```

For information about other options you can specify, see [create-document](#).

The system returns information like the following.

```
{
  "DocumentDescription":{
    "CreateDate":1.585061751738E9,
    "DefaultVersion":"1",
    "Description":"Use this template to update an EC2 Linux AMI. Requires one
    approver specified in the template and an approver specified in the
    request.",

  "Tags":[]
}
```

```
    ]  
  }  
}
```

The users in your organization or account who have been specified as template reviewers on the **Settings** tab in Change Manager are notified that a new change template is pending their review.

If an Amazon Simple Notification Service (Amazon SNS) topic has been specified for change templates, notifications are sent when the change template is rejected or approved. If you don't receive notifications related to this change template, you can return to Change Manager later to check on its status.

### Reviewing and approving or rejecting change templates

If you're specified as a reviewer for change templates in Change Manager, a capability of AWS Systems Manager, you're notified when a new change template, or new version of a change template, is awaiting your review. An Amazon Simple Notification Service (Amazon SNS) topic sends the notifications.

#### Note

This functionality depends on whether your account has been configured to use an Amazon SNS topic to send change template review notifications. For information about specifying a template reviewer notification topic, see [Task 1: Configuring Change Manager user identity management and template reviewers](#).

To review the change template, follow the link in your notification, sign in to the AWS Management Console, and follow the steps in this procedure.

### To review and approve or reject a change template

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Change Manager**.
3. In the **Change templates** section at the bottom of the **Overview** tab, choose the number in **Pending review**.

4. In the **Change templates** list, locate and choose the name of change template to review.
5. In the summary page, review the proposed content of the change template and do one of the following:
  - To approve the change template, which allows it to be used in change requests, choose **Approve**.
  - To reject the change template, which prevents it from being used in change requests, choose **Reject**.

## Deleting change templates

This topic describes how to delete templates that you have created in Change Manager, a capability of Systems Manager. If you are using Change Manager for an organization, this procedure is performed in your delegated administrator account.

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Change Manager**.
3. Choose the **Templates** tab.
4. Choose the name of the template to delete.
5. Choose **Actions, Delete template**.
6. In the confirmation dialog, enter the word **DELETE**, and then choose **Delete**.

## Working with change requests

A change request is a request in Change Manager to run an Automation runbook that updates one or more resources in your AWS or on-premises environments. A change request is created using a change template.

When you create a change request in Change Manager, a capability of AWS Systems Manager, one or more approvers in your organization or account must review and approve the request. Without the required approvals, the runbook workflow, which makes the changes you request, isn't permitted to run.

## Topics

- [Creating change requests](#)

- [Reviewing and approving or rejecting change requests](#)

## Creating change requests

When you create a change request in Change Manager, a capability of AWS Systems Manager, the change template you select typically does the following:

- Designates approvers for the change request or specifies how many approvals are required
- Specifies the Amazon Simple Notification Service (Amazon SNS) topic to use to notify approvers about your change request
- Specifies an Amazon CloudWatch alarm to monitor the runbook workflow for the change request
- Identifies which Automation runbooks you can choose from to make the requested change

In some cases, a change template might be configured so you specify your own Automation runbook to use, and to specify who should review and approve the request.

### Important

If you use Change Manager across an organization, we recommend always making changes from the delegated administrator account. Although you can make changes from other accounts in the organization, those changes won't be reported in or viewable from the delegated administrator account.

## Topics

- [About change request approvals](#)
- [Creating change requests \(console\)](#)
- [Creating change requests \(AWS CLI\)](#)

## About change request approvals

Depending on the requirements specified in a change template, change requests that you create from it can require approvals from up to five *levels* before the runbook workflow for the request can occur. For each of those levels, the template creator could specify up to five potential *approvers*. An approver isn't limited to a single user. An approver in this sense can also be an IAM group or IAM role. For IAM groups and IAM roles, one or more users belonging to the group or

role can provide approvals toward receiving the total number of approvals required for a change request. Template creators can also specify more approvers than the change template requires.

## Original approval workflows and updated and/or approvals

Using change templates created before January 23, 2023, an approval must be received from each specified approver for the change request to be approved at that level. For example, in the approval level setup shown in the following image, four approvers are specified. Specified approvers include two users (John Stiles and Ana Carolina Silva), a user group that contains three members (GroupOfThree), and a user role that represents ten users (RoleOfTen).

| Approver           | Type      | Required |        |
|--------------------|-----------|----------|--------|
| John Stiles        | IAM User  | 1        | Remove |
| Ana Carolina Silva | IAM User  | 1        | Remove |
| GroupOfThree       | IAM Group | 1        | Remove |
| RoleOfTen          | IAM Role  | 1        | Remove |

Buttons: Add approver ▼, Remove level

For the change request to be approved at this level, it must be approved by John Stiles, Ana Carolina Silva, one member of the GroupOfThree group, and one member of the RoleOfTen role.

Using change templates created on or after January 23, 2023, for each approval level, template creators can specify an overall total number of required approvals. Those approvals can come from any combination of users, groups, and roles that have been specified as approvers. A change template could require only one approval for a level but specify, for example, two individual users, two groups, and one role as potential approvers.

For example, in the approval level area shown in the following image, three approvals are required. The template-specified approvers include two users (John Stiles and Ana Carolina Silva), a user group that contains three members (GroupOfThree), and a user role that represents ten users (RoleOfTen).

### First-level approvals Remove level

Number of approvals required at this level

3 ▼

| Approver           | Type      |        |
|--------------------|-----------|--------|
| John Stiles        | IAM User  | Remove |
| Ana Carolina Silva | IAM User  | Remove |
| GroupOfThree       | IAM Group | Remove |
| RoleOfTen          | IAM Role  | Remove |

Add approver ▼

If all three users in the `GroupOfThree` group approve your change request, it is approved for that level. It's not necessary to receive an approval from each user, group, or role. The minimum number of approvals can come from any combination of potential approvers.

When your change request is created, notifications are sent to subscribers of the Amazon SNS topic that has been specified for approval notifications at that level. The change template creator might have specified the notification topic that must be used or allowed you to specify one.

After the minimum number of required approvals is received at one level, notifications are sent to approvers that are subscribed to the Amazon SNS topic for the next level, and so on.

No matter how many approval levels and approvers are specified, only one rejection to a change request is required to prevent the runbook workflow for that request from occurring.

### Creating change requests (console)

The following procedure describes how to create a change request by using the Systems Manager console.

## To create a change request (console)

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Change Manager**.
3. Choose **Create request**.
4. Search for and select a change template that you want to use for this change request.
5. Choose **Next**.
6. For **Name**, enter a name for the change request that makes its purpose easy to identify, such as **UpdateEC2LinuxAMI-us-east-2**.
7. For **Runbook**, select the runbook you want to use to make your requested change.

### Note

If the option to select a runbook isn't available, the change template author has specified which runbook must be used.

8. For **Change request information**, use Markdown to provide additional information about the change request to help reviewers decide whether to approve or reject the change request. The author of the template you're using might have provided instructions or questions for you to answer.

### Note

Markdown is a markup language that allows you to add wiki-style descriptions to documents and individual steps within the document. For more information about using Markdown, see [Using Markdown in AWS](#).

9. In the **Workflow start time** section, choose one of the following:
  - **Run the operation at a scheduled time** – For **Requested start time**, enter the date and time you propose for running the runbook workflow for this request. For **Estimated end time**, enter the date and time that you expect the runbook workflow to complete. (This time is an estimate only that you're providing for reviewers.)

**Tip**

Choose **View Change Calendar** to check for any blocking events for the time you specify.

- **Run the operation as soon as possible after approval** – If the change request is approved, the runbook workflow runs as soon as there is a non-restricted period when changes can be made.

10. In the **Change request approvals** section, do the following:

1. If **Approval type** options are presented, choose one of the following:

- **Automatic approval** – The change template you selected is configured to allow change requests to run automatically without review by any approvers. Continue to Step 11.

**Note**

The permissions specified in the IAM policies that govern your use of Systems Manager must not restrict you from submitting auto-approval change requests in order for them to run automatically.

- **Specify approvers** – You must add one or more users, groups, or IAM roles to review and approve this change request.

**Note**

You can choose to specify reviewers even if the permissions specified in the IAM policies that govern your use of Systems Manager allow you to run auto-approval change requests.

2. Choose **Add approver**, and then select one or more users, groups, or AWS Identity and Access Management (IAM) roles from the lists of available reviewers.

**Note**

One or more approvers might already be specified. This means that mandatory approvers are already specified in the change template you have selected. These approvers can't be removed from the request. If the **Add approver** button isn't

available, the template you have chosen doesn't allow additional reviewers to be added to requests.

For more information about approvals for change requests, see [About change request approvals](#).

3. Under **SNS topic to notify approvers**, choose one of the following to specify the Amazon SNS topic in your account to use for sending notifications to the approvers you are adding to this change request.

 **Note**

If the option to specify an Amazon SNS topic isn't available, the change template you selected already specifies the Amazon SNS topic to use.

- **Enter an SNS Amazon Resource Name (ARN)** – For **Topic ARN**, enter the ARN of an existing Amazon SNS topic. This topic can be in any of your organization's accounts.
- **Select an existing SNS topic** – For **Target notification topic**, select the ARN of an existing Amazon SNS topic in your current account. (This option isn't available if you haven't yet created any Amazon SNS topics in your current AWS account and AWS Region.)

 **Note**

The Amazon SNS topic you select must be configured to specify the notifications it sends and the subscribers they're sent to. Its access policy must also grant permissions to Systems Manager so Change Manager can send notifications. For information, see [Configuring Amazon SNS topics for Change Manager notifications](#).

4. Choose **Add notification**.
11. Choose **Next**.
12. For **IAM role**, select an IAM role *in your current account* that has the permissions needed to run the runbooks that are specified for this change request.

This role is also referred to as the service role, or assume role, for Automation. For more information about this role, see [Setting up Automation](#).

13. In the **Deployment location** section, choose one of the following:

**Note**

If you're using Change Manager with a single AWS account only and not with an organization set up in AWS Organizations, you don't need to specify a deployment location.

- **Apply change to this account** – The runbook workflow runs in the current account only. For an organization, this means the delegated administrator account.
- **Apply change to multiple organizational units (OUs)** – Do the following:
  1. For **Accounts and organizational units (OUs)**, enter the ID of a member account in your organization, in the format **123456789012**, or the ID of an organizational unit, in the format **o-o96EXAMPLE**.
  2. (Optional) For **Execution role name**, enter the name of the IAM role *in the target account* or OU that has the permissions needed to run the runbooks that are specified for this change request. All accounts in any OU you specify should use the same name for this role.
  3. (Optional) Choose **Add another target location** for each additional account or OU you want to specify and repeat steps a and b.
  4. For **Target AWS Region**, select the Region to make the change in, such as Ohio (us-east-2) for the US East (Ohio) Region.
  5. Expand **Rate control**.

For **Concurrency**, enter a number, then from the list select whether this represents the number or percentage of accounts the runbook workflow can run in at the same time.

For **Error threshold**, enter a number, then from the list select whether this represents the number or percentage of accounts where runbook workflow can fail before the operation is stopped.

**14. In the Deployment targets section, do the following:**

1. Choose one of the following:
  - **Single resource** – The change is to be made for just one resource. For example, a single node or a single Amazon Machine Image (AMI), depending on the operation defined in the runbooks for this change request.

- **Multiple resources** – For **Parameter**, select from the available parameters from the runbooks for this change request. This selection reflects the type of resource being updated.

For example, if the runbook for this change request is `AWS-RetartEC2Instance`, you might choose `InstanceId`, and then define which instances are updated by selecting from the following:

- **Specify tags** – Enter a key-value pair that all resources to be updated are tagged with.
- **Choose a resource group** – Choose the name of the resource group that all resources to be updated belong to.
- **Specify parameter values** – Identify the resources to update in the **Runbook parameters** section.
- **Target all instances** – Make the change on all managed nodes in the target locations.

2. If you chose **Multiple resources**, expand **Rate control**.

For **Concurrency**, enter a number, then from the list select whether this represents the number or percentage of targets the runbook workflow can update at the same time.

For **Error threshold**, enter a number, then from the list select whether this represents the number or percentage of targets where the update can fail before the operation is stopped.

15. If you chose **Specify parameter values** to update multiple resources in the previous step: In the **Runbook parameters** section, specify values for the required input parameters. The parameter values you must supply are based on the contents of the Automation runbooks associated with the change template you chose.

For example, if the change template uses the `AWS-RetartEC2Instance` runbook, then you must enter one or more instance IDs for the **InstanceId** parameter. Alternatively, choose **Show interactive instance picker** and select available instances one by one.

16. Choose **Next**.

17. In the **Review and submit** page, double-check the resources and options you have specified for this change request.

Choose the **Edit** button for any section you want to make changes to.

When you're satisfied with the change request details, choose **Submit for approval**.

If an Amazon SNS topic has been specified in the change template you chose for the request, notifications are sent when the request is rejected or approved. If you don't receive notifications for the request, you can return to Change Manager to check the status of your request.

## Creating change requests (AWS CLI)

You can create a change request using the AWS Command Line Interface (AWS CLI) by specifying options and parameters for the change request in a JSON file and using the `--cli-input-json` option to include it in your command.

### To create a change request (AWS CLI)

1. Install and configure the AWS CLI or the AWS Tools for PowerShell, if you haven't already.

For information, see [Installing or updating the latest version of the AWS CLI](#) and [Installing the AWS Tools for PowerShell](#).

2. Create a JSON file on your local machine with a name such as `MyChangeRequest.json` and paste the following content into it.

Replace *placeholders* with values for your change request.

#### Note

This sample JSON creates a change request using the `AWS-HelloWorldChangeTemplate` change template and `AWS-HelloWorld` runbook. To help you adapt this sample for your own change requests, see [StartChangeRequestExecution](#) in the *AWS Systems Manager API Reference* for information about all available parameters

For more information about approvals for change requests, see [About change request approvals](#).

        "Parameters": {
            "AutomationAssumeRole": [
                "arn:aws:iam::123456789012:role/MyChangeManagerAssumeRole"
            ]
        }
    }
],
"ChangeDetails": "### Document Name: HelloWorldChangeTemplate\n\n## What does this document do?\nThis change template demonstrates the feature set available for creating change templates for Change Manager. This template starts a Runbook workflow for the Automation document called AWS-HelloWorld.\n\n## Input Parameters\n\n* ApproverSnsTopicArn: (Required) Amazon Simple Notification Service ARN for approvers.\n* Approver: (Required) The name of the approver to send this request to.\n* ApproverType: (Required) The type of reviewer.\n  * Allowed Values: IamUser, IamGroup, IamRole, SSOGroup, SSOUser\n\n## Output Parameters\nThis document has no outputs \n"
}

```

3. In the directory where you created the JSON file, run the following command.

```
aws ssm start-change-request-execution --cli-input-json file://MyChangeRequest.json
```

The system returns information like the following.

```
{  
  "AutomationExecutionId": "b3c1357a-5756-4839-8617-2d2a4EXAMPLE"  
}
```

## Reviewing and approving or rejecting change requests

If you're specified as a reviewer for a change request in Change Manager, a capability of AWS Systems Manager, you're notified through an Amazon Simple Notification Service (Amazon SNS) topic when a new change request is awaiting your review.

### Note

This functionality depends on whether an Amazon SNS was specified in the change template for sending review notifications. For information, see [Configuring Amazon SNS topics for Change Manager notifications](#).

To review the change request, you can follow the link in your notification, or sign in to the AWS Management Console directly and follow the steps in this procedure.

### Note

If an Amazon SNS topic is assigned for reviewers in a change template, notifications are sent to the topic's subscribers when the change request changes status.

For more information about approvals for change requests, see [About change request approvals](#).

## Reviewing and approving or rejecting change requests (console)

The following procedures describe how to use the Systems Manager console to review and approve or reject change requests.

## To review and approve or reject a single change request

1. Open the link in the email notification you received and sign in to the AWS Management Console, which directs you to the change request for your review.
2. In the summary page, review the proposed content of the change request.

To approve the change request, choose **Approve**. In the dialog box, provide any comments you want to add for this approval, and then choose **Approve**. The runbook workflow represented by this request starts to run either when scheduled, or as soon as changes aren't blocked by any restrictions.

-or-

To reject the change request, choose **Reject**. In the dialog box, provide any comments you want to add for this rejection, and then choose **Reject**.

## To review and approve or reject change requests in bulk

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Change Manager**.
3. Choose the **Approvals** tab.
4. (Optional) Review the details of requests pending your approval by choosing the name of each request, and then return to the **Approvals** tab.
5. Select the check box of each change request that you want to approve.

-or-

Select the check box of each change request that you want to reject.

6. In the dialog box, provide any comments you want to add for this approval or rejection.
7. Depending on whether you're approving or rejecting the selected change requests, choose **Approve** or **Reject**.

## Reviewing and approving or rejecting a change request (command line)

The following procedure describes how to use the AWS Command Line Interface (AWS CLI) (on Linux, macOS, or Windows) to review and approve or reject a change request.

## To review and approve or reject a change request

1. Install and configure the AWS Command Line Interface (AWS CLI), if you haven't already.

For information, see [Installing or updating the latest version of the AWS CLI](#).

2. Create a JSON file on your local machine that specifies the parameters for your AWS CLI call.

```
{
  "OpsItemFilters":
  [
    {
      "Key": "OpsItemType",
      "Values": ["/aws/changerequest"],
      "Operator": "Equal"
    }
  ],
  "MaxResults": number
}
```

You can filter the results for a specific approver by specifying the approver's Amazon Resource Name (ARN) in the JSON file. Here is an example.

```
{
  "OpsItemFilters":
  [
    {
      "Key": "OpsItemType",
      "Values": ["/aws/changerequest"],
      "Operator": "Equal"
    },
    {
      "Key": "ChangeRequestByApproverArn",
      "Values": ["arn:aws:iam::account-id:user/user-name"],
      "Operator": "Equal"
    }
  ],
  "MaxResults": number
}
```

3. Run the following command to view the maximum number of change requests you specified in the JSON file.

## Linux & macOS

```
aws ssm describe-ops-items \  
--cli-input-json file://filename.json
```

## Windows

```
aws ssm describe-ops-items ^  
--cli-input-json file://filename.json
```

4. Run the following command to approve or reject a change request.

## Linux & macOS

```
aws ssm send-automation-signal \  
--automation-execution-id ID \  
--signal-type Approve_or_Reject \  
--payload Comment="message"
```

## Windows

```
aws ssm send-automation-signal ^  
--automation-execution-id ID ^  
--signal-type Approve_or_Reject ^  
--payload Comment="message"
```

If an Amazon SNS topic has been specified in the change template you chose for the request, notifications are sent when the request is rejected or approved. If you don't receive notifications for the request, you can return to Change Manager to check the status of your request. For information about other options when using this command, see [send-automation-signal](#) in the AWS Systems Manager section of the *AWS CLI Command Reference*.

## Reviewing change request details, tasks, and timelines (console)

You can view information about a change request, including requests for which changes have already been processed, in the dashboard of Change Manager, a capability of AWS Systems Manager. These details include a link to the Automation operation that runs the runbooks that make the change. An Automation execution ID is generated when the request is created, but the

process doesn't run until all approvals have been given and no restrictions are in place to block the change.

### To review change request details, tasks, and timelines

1. In the navigation pane, choose **Change Manager**.
2. Choose the **Requests** tab.
3. In the **Change requests** section, search for the change request you want to review.

You can use the **Create date range** options to limit results to a specific time period.

You can filter requests by the following properties:

- Status
- Request ID
- Approver
- Requester

For example, to view details about all change requests that have completed successfully in the past 24 hours, do the following:

1. For **Create date range**, choose **1d**.
2. In the search box, select **Status, CompletedWithSuccess**.
3. In the results, choose the name of the successfully completed change request to review results for.
4. View information about the change request on the following tabs:
  - **Request details** – View basic details about the change request, including the requester, the change template, and the Automation runbooks selected for the change. You can also follow a link to the Automation operation details and view information about any runbook parameters specified in the request, Amazon CloudWatch alarms assigned to the change request, and approvals and comments provided for the request.
  - **Task** – View information about the task in the change, including task status for completed change requests, the targeted resources, the steps in the associated Automation runbooks, and concurrency and error threshold details.

- **Timeline** – View a summary of all events associated with the change request, listed by date and time. The summary indicates when the change request was created, actions by assigned approvers, a note of when approved change requests are scheduled to run, runbook workflow details, and status changes for the overall change process and each step in the runbook.
- **Associated events** – View auditable details about change requests that are recorded in [AWS CloudTrail Lake](#). Details include which API actions were run, the request parameters included for those actions, the user account that ran the action, the resources updated during the process, and more.

When you enable CloudTrail Lake event tracking, CloudTrail Lake creates an event data store for events related to your change requests. The event details are available for the account or organization where the change request ran. You can turn on CloudTrail Lake event tracking from any change request in your account or organization. For information about enabling CloudTrail Lake integration and creating an event data store, see [Monitoring your change request events](#).

 **Note**

There is a charge to use **CloudTrail Lake**. For details, see [AWS CloudTrail pricing](#).

## Viewing aggregated counts of change requests (command line)

You can view aggregated counts of change requests in Change Manager, a capability of AWS Systems Manager, by using the [GetOpsSummary](#) API operation. This API operation can return counts for a single AWS account in a single AWS Region or for multiple accounts and multiple Regions.

 **Note**

If you want to view aggregated counts of change requests for multiple AWS accounts and multiple AWS Regions, you must set up and configure a resource data sync. For more information, see [Creating a resource data sync for Inventory](#).

The following procedure describes how to use the AWS Command Line Interface (AWS CLI) (on Linux, macOS, or Windows) to view aggregated counts of change requests.

## To view aggregated counts of change requests

1. Install and configure the AWS Command Line Interface (AWS CLI), if you haven't already.

For information, see [Installing or updating the latest version of the AWS CLI](#).

2. Run one of the following commands.

### Single account and Region

This command returns a count of all change requests for the AWS account and AWS Region for which your AWS CLI session is configured.

#### Linux & macOS

```
aws ssm get-ops-summary \  
--filters Key=AWS:OpsItem.OpsItemType,Values="/aws/changerequests",Type=Equal \  
--aggregators AggregatorType=count,AttributeName=Status,TypeName=AWS:OpsItem
```

#### Windows

```
aws ssm get-ops-summary ^  
--filters Key=AWS:OpsItem.OpsItemType,Values="/aws/changerequests",Type=Equal ^  
--aggregators AggregatorType=count,AttributeName=Status,TypeName=AWS:OpsItem
```

The call returns information like the following.

```
{  
  "Entities": [  
    {  
      "Data": {  
        "AWS:OpsItem": {  
          "Content": [  
            {  
              "Count": "38",  
              "Status": "Open"  
            }  
          ]  
        }  
      }  
    }  
  ]  
}
```

```
}

```

## Multiple accounts and/or Regions

This command returns a count of all change requests for the AWS accounts and AWS Regions specified in the resource data sync.

### Linux & macOS

```
aws ssm get-ops-summary \
  --sync-name resource_data_sync_name \
  --filters Key=AWS:OpsItem.OpsItemType,Values="/aws/
changerequests",Type=Equal \
  --aggregators AggregatorType=count,AttributeName=Status,TypeName=AWS:OpsItem

```

### Windows

```
aws ssm get-ops-summary ^
  --sync-name resource_data_sync_name ^
  --filters Key=AWS:OpsItem.OpsItemType,Values="/aws/
changerequests",Type=Equal ^
  --aggregators AggregatorType=count,AttributeName=Status,TypeName=AWS:OpsItem

```

The call returns information like the following.

```
{
  "Entities": [
    {
      "Data": {
        "AWS:OpsItem": {
          "Content": [
            {
              "Count": "43",
              "Status": "Open"
            },
            {
              "Count": "2",
              "Status": "Resolved"
            }
          ]
        }
      }
    }
  ]
}
```

```

    }
  }
]
}

```

## Multiple accounts and a specific Region

This command returns a count of all change requests for the AWS accounts specified in the resource data sync. However, it only returns data from the Region specified in the command.

### Linux & macOS

```

aws ssm get-ops-summary \
  --sync-name resource_data_sync_name \
  --filters Key=AWS:OpsItem.SourceRegion,Values='Region',Type=Equal \
  Key=AWS:OpsItem.OpsItemType,Values="/aws/changerequests",Type=Equal \
  --aggregators AggregatorType=count,AttributeName=Status,TypeName=AWS:OpsItem

```

### Windows

```

aws ssm get-ops-summary ^
  --sync-name resource_data_sync_name ^
  --filters Key=AWS:OpsItem.SourceRegion,Values='Region',Type=Equal \
  Key=AWS:OpsItem.OpsItemType,Values="/aws/changerequests",Type=Equal ^
  --aggregators AggregatorType=count,AttributeName=Status,TypeName=AWS:OpsItem

```

## Multiple accounts and Regions with output grouped by Region

This command returns a count of all change requests for the AWS accounts and AWS Regions specified in the resource data sync. The output displays count information per Region.

### Linux & macOS

```

aws ssm get-ops-summary \
  --sync-name resource_data_sync_name \
  --filters Key=AWS:OpsItem.OpsItemType,Values="/aws/
changerequests",Type=Equal \
  --aggregators
  '[{"AggregatorType":"count","TypeName":"AWS:OpsItem","AttributeName":"Status","Aggregat
[{"AggregatorType":"count","TypeName":"AWS:OpsItem","AttributeName":"SourceRegion"}]]]'

```

## Windows

```
aws ssm get-ops-summary ^
  --sync-name resource_data_sync_name ^
  --filters Key=AWS:OpsItem.OpsItemType,Values="/aws/
changerequests",Type=Equal ^
  --aggregators
  '[{"AggregatorType":"count","TypeName":"AWS:OpsItem","AttributeName":"Status","Aggregat
[{"AggregatorType":"count","TypeName":"AWS:OpsItem","AttributeName":"SourceRegion"}]]'
```

The call returns information like the following.

```
{
  "Entities": [
    {
      "Data": {
        "AWS:OpsItem": {
          "Content": [
            {
              "Count": "38",
              "SourceRegion": "us-east-1",
              "Status": "Open"
            },
            {
              "Count": "4",
              "SourceRegion": "us-east-2",
              "Status": "Open"
            },
            {
              "Count": "1",
              "SourceRegion": "us-west-1",
              "Status": "Open"
            },
            {
              "Count": "2",
              "SourceRegion": "us-east-2",
              "Status": "Resolved"
            }
          ]
        }
      }
    }
  ]
}
```

```

    }
  ]
}

```

## Multiple accounts and Regions with output grouped by accounts and Regions

This command returns a count of all change requests for the AWS accounts and AWS Regions specified in the resource data sync. The output groups the count information by accounts and Regions.

### Linux & macOS

```

aws ssm get-ops-summary \
  --sync-name resource_data_sync_name \
  --filters Key=AWS:OpsItem.OpsItemType,Values="/aws/
changerequests",Type=Equal \
  --aggregators
  '[{"AggregatorType":"count","TypeName":"AWS:OpsItem","AttributeName":"Status","Aggregat
[{"AggregatorType":"count","TypeName":"AWS:OpsItem","AttributeName":"SourceAccountId","A
[{"AggregatorType":"count","TypeName":"AWS:OpsItem","AttributeName":"SourceRegion"}]]}]

```

### Windows

```

aws ssm get-ops-summary ^
  --sync-name resource_data_sync_name ^
  --filters Key=AWS:OpsItem.OpsItemType,Values="/aws/
changerequests",Type=Equal ^
  --aggregators
  '[{"AggregatorType":"count","TypeName":"AWS:OpsItem","AttributeName":"Status","Aggregat
[{"AggregatorType":"count","TypeName":"AWS:OpsItem","AttributeName":"SourceAccountId","A
[{"AggregatorType":"count","TypeName":"AWS:OpsItem","AttributeName":"SourceRegion"}]]}]

```

The call returns information like the following.

```

{
  "Entities": [
    {
      "Data": {
        "AWS:OpsItem": {
          "Content": [

```

```
{
  "Count": "38",
  "SourceAccountId": "123456789012",
  "SourceRegion": "us-east-1",
  "Status": "Open"
},
{
  "Count": "4",
  "SourceAccountId": "111122223333",
  "SourceRegion": "us-east-2",
  "Status": "Open"
},
{
  "Count": "1",
  "SourceAccountId": "111122223333",
  "SourceRegion": "us-west-1",
  "Status": "Open"
},
{
  "Count": "2",
  "SourceAccountId": "444455556666",
  "SourceRegion": "us-east-2",
  "Status": "Resolved"
},
{
  "Count": "1",
  "SourceAccountId": "222222222222",
  "SourceRegion": "us-east-1",
  "Status": "Open"
}
]
}
}
```

## Auditing and logging Change Manager activity

You can audit activity in Change Manager, a capability of AWS Systems Manager, by using Amazon CloudWatch and AWS CloudTrail alarms.

For more information about auditing and logging options for Systems Manager, see [Monitoring AWS Systems Manager](#).

## Audit Change Manager activity using CloudWatch alarms

You can configure and assign a CloudWatch alarm to a change template. If any conditions defined in the alarm are met, the actions specified for the alarm are taken. In the alarm configuration, you can specify an Amazon Simple Notification Service (Amazon SNS) topic to notify when an alarm condition is met.

For information about creating a Change Manager template, see [Working with change templates](#).

For information about creating CloudWatch alarms, see [Using CloudWatch Alarms](#) in the *Amazon CloudWatch User Guide*.

## Audit Change Manager activity using CloudTrail

CloudTrail captures API calls made in the Systems Manager console, the AWS Command Line Interface (AWS CLI), and the Systems Manager SDK. You can view the information in the CloudTrail console or in an Amazon Simple Storage Service (Amazon S3) bucket, where it's stored. One bucket is used for all CloudTrail logs for your account.

Logs of Change Manager actions show change template document creation, change template and change request approvals and rejections, activity generated by Automation runbooks, and more. For more information about viewing and using CloudTrail logs of Systems Manager activity, see [Logging AWS Systems Manager API calls with AWS CloudTrail](#).

## Troubleshooting Change Manager

Use the following information to help you troubleshoot problems with Change Manager, a capability of AWS Systems Manager.

### Topics

- [“Group {GUID} not found” error during change request approvals when using Active Directory \(groups\)](#)

## “Group **{GUID}** not found” error during change request approvals when using Active Directory (groups)

**Problem:** When AWS IAM Identity Center (IAM Identity Center) is used for user identity management, a member of an Active Directory group who is granted approval permissions in Change Manager receives a “not authorized” or “group not found” error.

- **Solution:** When you select Active Directory groups in IAM Identity Center for access to the AWS Management Console, the system schedules a periodic synchronization that copies information from those Active Directory groups into IAM Identity Center. This process must complete before users authorized through Active Directory group membership can successfully approve a request. For more information, see [Connect to your Microsoft AD directory](#) in the *AWS IAM Identity Center User Guide*.

## AWS Systems Manager Automation

Automation, a capability of AWS Systems Manager, simplifies common maintenance, deployment, and remediation tasks for AWS services like Amazon Elastic Compute Cloud (Amazon EC2), Amazon Relational Database Service (Amazon RDS), Amazon Redshift, Amazon Simple Storage Service (Amazon S3), and many more. To get started with Automation, open the [Systems Manager console](#). In the navigation pane, choose **Automation**.

Automation helps you to build automated solutions to deploy, configure, and manage AWS resources at scale. With Automation, you have granular control over the concurrency of your automations. This means you can specify how many resources to target concurrently, and how many errors can occur before an automation is stopped.

To help you get started with Automation, AWS develops and maintains several pre-defined runbooks. Depending on your use case, you can use these pre-defined runbooks that perform a variety of tasks, or create your own custom runbooks that might better suit your needs. To monitor the progress and status of your automations, you can use the Systems Manager Automation console, or your preferred command line tool. Automation also integrates with Amazon EventBridge to help you build event-driven architecture at scale.

### How can Automation benefit my organization?

Automation offers these benefits:

- **Scripting support in runbook content**

Using the `aws:executeScript` action, you can run custom Python and PowerShell functions directly from your runbooks. This provides you greater flexibility in creating your custom runbooks because you can complete various tasks that other Automation actions don't support. You also have greater control over the logic of the runbook. For an example of how this action can be used and how it can help to improve an existing automated solution, see [Authoring Automation runbooks](#).

- **Run automations across multiple AWS accounts and AWS Regions from a centralized location**

Administrators can run automations on resources across multiple accounts and Regions from the Systems Manager console.

- **Enhanced operations security**

Administrators have a centralized place to grant and revoke access to runbooks. Using only AWS Identity and Access Management (IAM) policies, you can control which individual users or groups in your organization can use Automation and which runbooks they can access.

- **Automate common IT tasks**

Automating common tasks can help improve operational efficiency, enforce organizational standards, and reduce operator errors. For example, you can use the `AWS-UpdateCloudFormationStackWithApproval` runbook to update resources that were deployed by using an AWS CloudFormation template. The update applies a new template. You can configure the Automation to request approval by one or more users before the update begins.

- **Safely perform disruptive tasks in bulk**

Automation includes features, like rate controls, that allow you to control the deployment of an automation across your fleet by specifying a concurrency value and an error threshold. For more information about working with rate controls, see [Run automated operations at scale](#).

- **Streamline complex tasks**

Automation provides pre-defined runbooks that streamline complex and time-consuming tasks such as creating golden Amazon Machine Images (AMIs). For example, you can use the `AWS-UpdateLinuxAmi` and `AWS-UpdateWindowsAmi` runbooks to create golden AMIs from a source AMI. Using these runbooks, you can run custom scripts before and after updates are applied. You can also include or exclude specific software packages from being installed. For examples of how to use these runbooks, see [Tutorials](#).

- **Define constraints for inputs**

You can define constraints in custom runbooks to limit the values that Automation will accept for a particular input parameter. For example, `allowedPattern` will only accept values for an input parameter that match the regular expression you define. If you specify `allowedValues` for an input parameter, only the values you've specified in the runbook are accepted.

- **Log automation action output to Amazon CloudWatch Logs**

To meet operational or security requirements in your organization, you might need to provide a record of the scripts run during a runbook. With CloudWatch Logs, you can monitor, store, and access log files from various AWS services. You can send output from the `aws:executeScript` action to a CloudWatch Logs log group for debugging and troubleshooting purposes. Log data can be sent to your log group with or without AWS KMS encryption using your KMS key. For more information, see [Logging Automation action output with CloudWatch Logs](#).

- **Amazon EventBridge integration**

Automation is supported as a *target* type in Amazon EventBridge rules. This means you can trigger runbooks by using events. For more information, see [Monitoring Systems Manager events with Amazon EventBridge](#) and [Reference: Amazon EventBridge event patterns and types for Systems Manager](#).

- **Share organizational best practices**

You can define best practices for resource management, operations tasks, and more in runbooks that you share across accounts and Regions.

## Who should use Automation?

- Any AWS customer who wants to improve their operational efficiency at scale, reduce errors associated with manual intervention, and reduce time to resolution of common issues.
- Infrastructure experts who want to automate deployment and configuration tasks.
- Administrators who want to reliably resolve common issues, improve troubleshooting efficiency, and reduce repetitive operations.
- Users who want to automate a task they normally perform manually.

## What is an automation?

An *automation* consists of all of the tasks that are defined in a runbook, and are performed by the Automation service. Automation uses the following components to run automations.

| Concept            | Details   |
|--------------------|---|
| Automation runbook | <p>A Systems Manager Automation runbook defines the automation (the actions that Systems Manager performs on your managed nodes and AWS resources). Automation includes several pre-defined runbooks that you can use to perform common tasks like restarting one or more Amazon EC2 instances or creating an Amazon Machine Image (AMI). You can create your own runbooks as well. Runbooks use YAML or JSON, and they include steps and parameters that you specify. Steps run in sequential order. For more information, see <a href="#">Creating your own runbooks</a>.</p> <p>Runbooks are Systems Manager documents of type <code>Automation</code>, as opposed to <code>Command</code>, <code>Policy</code>, <code>Session</code> documents. Runbooks support schema version 0.3. Command documents use schema version 1.2, 2.0, or 2.2. Policy documents use schema version 2.0 or later.</p> |
| Automation action  | <p>The automation defined in a runbook includes one or more steps. Each step is associated with a particular action. The action determines the inputs, behavior, and outputs of the step. Steps are defined in the <code>mainSteps</code> section of your runbook. Automation supports 20 distinct action types. For more information,</p>  |

| Concept                       | Details   |
|-------------------------------|---|
| Automation quota              | <p>Each AWS account can run 100 automations simultaneously. This includes child automations (automations that are started by another automation), and rate control automations. If you attempt to run more automations than this, Systems Manager adds the additional automations to a queue and displays a status of Pending. This quota can be adjusted using adaptive concurrency. For more information, see <a href="#">Allowing Automation to adapt to your concurrency needs</a>. For more information about running automations, see <a href="#">Run an automated operation powered by Systems Manager Automation</a>.</p> |
| Automation queue quota        | <p>If you attempt to run more automations than the concurrent automation limit, subsequent automations are added to a queue. Each AWS account can queue 5,000 automations. When an automation is complete (or reaches a terminal state), the first automation in the queue is started.</p>  |
| Rate control automation quota | <p>Each AWS account can run 25 rate control automations simultaneously. If you attempt to run more rate control automations than the concurrent rate control automation limit, Systems Manager adds the subsequent rate control automations to a queue and displays a status of Pending. For more information about running rate control automations, see <a href="#">Run automated operations at scale</a>.</p>  |

| Concept                             | Details   |
|-------------------------------------|---|
| Rate control automation queue quota | If you attempt to run more automations than the concurrent rate control automation limit, subsequent automations are added to a queue. Each AWS account can queue 1,000 rate control automations. When an automation is complete (or reaches a terminal state), the first automation in the queue is started. |

## Setting up Automation

To set up Automation, a capability of AWS Systems Manager, you must verify user access to the Automation service and situationally configure roles so that the service can perform actions on your resources. We also recommend that you opt in to the adaptive concurrency mode in your Automation preferences. Adaptive concurrency automatically scales your automation quota to

meet your needs. For more information, see [Allowing Automation to adapt to your concurrency needs](#).

To ensure proper access to AWS Systems Manager Automation, review the following user and service role requirements.

### Verifying user access for runbooks

Verify that you have permission to use runbooks. If your user, group, or role is assigned administrator permissions, then you have access to Systems Manager Automation. If you don't have administrator permissions, then an administrator must give you permission by assigning the `AmazonSSMFullAccess` managed policy, or a policy that provides comparable permissions, to your user, group, or role.

#### Important

The IAM policy `AmazonSSMFullAccess` grants permissions to Systems Manager actions. However, some runbooks require permissions to other services, such as the runbook `AWS-ReleaseElasticIP`, which requires IAM permissions for `ec2:ReleaseAddress`. Therefore, you must review the actions taken in a runbook to ensure your user, group, or role is assigned the necessary permissions to perform the actions included in the runbook.

### Configuring a service role (assume role) access for automations

Automations can be initiated under the context of a service role (or *assume role*). This allows the service to perform actions on your behalf. If you don't specify an assume role, Automation uses the context of the user who invoked the automation.

However, the following situations require that you specify a service role for Automation:

- When you want to restrict a user's permissions on a resource, but you want the user to run an automation that requires elevated permissions. In this scenario, you can create a service role with elevated permissions and allow the user to run the automation.
- When you create a Systems Manager State Manager association that runs a runbook.
- When you have operations that you expect to run longer than 12 hours.
- When you're running a runbook not owned by Amazon that uses the `aws:executeScript` action to call an AWS API operation or to act on an AWS resource. For information, see [Permissions for using runbooks](#).

If you need to create a service role for Automation, you can use one of the following methods.

## Topics

- [Create service roles for Automation by using AWS CloudFormation](#)
- [Create the service roles for Automation using the console](#)
- [Allowing Automation to adapt to your concurrency needs](#)
- [Implement change controls for Automation](#)

## Create service roles for Automation by using AWS CloudFormation

You can create a service role for Automation, a capability of AWS Systems Manager, from an AWS CloudFormation template. After you create the service role, you can specify the service role in runbooks using the parameter `AutomationAssumeRole`.

### Create the service role using AWS CloudFormation

Use the following procedure to create the required AWS Identity and Access Management (IAM) role for Systems Manager Automation by using AWS CloudFormation.

#### To create the required IAM role

1. Download and unzip the [AWS-SystemsManager-AutomationServiceRole.zip](#) file. This file includes the `AWS-SystemsManager-AutomationServiceRole.yaml` AWS CloudFormation template file.
2. Open the AWS CloudFormation console at <https://console.aws.amazon.com/cloudformation>.
3. Choose **Create Stack**.
4. In the **Specify template** section, choose **Upload a template file**.
5. Choose **Browse**, and then choose the `AWS-SystemsManager-AutomationServiceRole.yaml` AWS CloudFormation template file.
6. Choose **Next**.
7. On the **Specify stack details** page, in the **Stack name** field, enter a name.
8. On the **Configure stack options** page, you don't need to make any selections. Choose **Next**.
9. On the **Review** page, scroll down and choose the **I acknowledge that AWS CloudFormation might create IAM resources** option.
10. Choose **Create**.

CloudFormation shows the **CREATE\_IN\_PROGRESS** status for approximately three minutes. The status changes to **CREATE\_COMPLETE** after the stack is created and your roles are ready to use.

### Important

If you run an automation workflow that invokes other services by using an AWS Identity and Access Management (IAM) service role, be aware that the service role must be configured with permission to invoke those services. This requirement applies to all AWS Automation runbooks (AWS- \* runbooks) such as the `AWS-ConfigureS3BucketLogging`, `AWS-CreateDynamoDBBackup`, and `AWS-RestartEC2Instance` runbooks, to name a few. This requirement also applies to any custom Automation runbooks you create that invoke other AWS services by using actions that call other services. For example, if you use the `aws:executeAwsApi`, `aws:createStack`, or `aws:copyImage` actions, configure the service role with permission to invoke those services. You can give permissions to other AWS services by adding an IAM inline policy to the role. For more information, see [\(Optional\) Add an Automation inline policy or customer managed policy to invoke other AWS services](#).

## Copy role information for Automation

Use the following procedure to copy information about the Automation service role from the AWS CloudFormation console. You must specify these roles when you use a runbook.

### Note

You don't need to copy role information using this procedure if you run the `AWS-UpdateLinuxAmi` or `AWS-UpdateWindowsAmi` runbooks. These runbooks already have the required roles specified as default values. The roles specified in these runbooks use IAM managed policies.

## To copy the role names

1. Open the AWS CloudFormation console at <https://console.aws.amazon.com/cloudformation>.
2. Select the Automation **Stack name** you created in the previous procedure.
3. Choose the **Resources** tab.

4. Choose the **Physical ID** link for **AutomationServiceRole**. The IAM console opens to a summary of the Automation service role.
5. Copy the Amazon Resource Name (ARN) next to **Role ARN**. The ARN is similar to the following:  
`arn:aws:iam::12345678:role/AutomationServiceRole`
6. Paste the ARN into a text file to use later.

You have finished configuring the service role for Automation. You can now use the Automation service role ARN in your runbooks.

## Create the service roles for Automation using the console

If you need to create a service role for Automation, a capability of AWS Systems Manager, complete the following tasks. For more information about when a service role is required for Automation, see [Setting up Automation](#).

### Tasks

- [Task 1: Create a service role for Automation](#)
- [Task 2: Attach the iam:PassRole policy to your Automation role](#)

### Task 1: Create a service role for Automation

Use the following procedure to create a service role (or *assume role*) for Systems Manager Automation.

#### Note

You can also use this role in runbooks, such as the `AWS-CreateManagedLinuxInstance` runbook. Using this role, or the Amazon Resource Name (ARN) of an AWS Identity and Access Management (IAM) role, in runbooks allows Automation to perform actions in your environment, such as launch new instances and perform actions on your behalf.

### To create an IAM role and allow Automation to assume it

1. Open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **Roles**, and then choose **Create role**.
3. Under **Select type of trusted entity**, choose **AWS service**.

4. In the **Choose a use case** section, choose **Systems Manager**, and then choose **Next: Permissions**.
5. On the **Attached permissions policy** page, search for the **AmazonSSMAutomationRole** policy, choose it, and then choose **Next: Review**.
6. On the **Review** page, enter a name in the **Role name** box, and then enter a description.
7. Choose **Create role**. The system returns you to the **Roles** page.
8. On the **Roles** page, choose the role you just created to open the **Summary** page. Note the **Role Name** and **Role ARN**. You will specify the role ARN when you attach the **iam:PassRole** policy to your IAM account in the next procedure. You can also specify the role name and the ARN in runbooks.

#### Note

The `AmazonSSMAutomationRole` policy assigns the Automation role permission to a subset of AWS Lambda functions within your account. These functions begin with "Automation". If you plan to use Automation with Lambda functions, the Lambda ARN must use the following format:

```
"arn:aws:lambda:*:*:function:Automation*"
```

If you have existing Lambda functions whose ARNs don't use this format, then you must also attach an additional Lambda policy to your automation role, such as the **AWSLambdaRole** policy. The additional policy or role must provide broader access to Lambda functions within the AWS account.

After creating your service role, we recommend editing the trust policy to help prevent the cross-service confused deputy problem. The *confused deputy problem* is a security issue where an entity that doesn't have permission to perform an action can coerce a more-privileged entity to perform the action. In AWS, cross-service impersonation can result in the confused deputy problem. Cross-service impersonation can occur when one service (the *calling service*) calls another service (the *called service*). The calling service can be manipulated to use its permissions to act on another customer's resources in a way it should not otherwise have permission to access. To prevent this, AWS provides tools that help you protect your data for all services with service principals that have been given access to resources in your account.

We recommend using the [aws:SourceArn](#) and [aws:SourceAccount](#) global condition context keys in resource policies to limit the permissions that Automation gives another service to the

resource. If the `aws:SourceArn` value doesn't contain the account ID, such as an Amazon S3 bucket ARN, you must use both global condition context keys to limit permissions. If you use both global condition context keys and the `aws:SourceArn` value contains the account ID, the `aws:SourceAccount` value and the account in the `aws:SourceArn` value must use the same account ID when used in the same policy statement. Use `aws:SourceArn` if you want only one resource to be associated with the cross-service access. Use `aws:SourceAccount` if you want to allow any resource in that account to be associated with the cross-service use. The value of `aws:SourceArn` must be the ARN for automation executions. If you don't know the full ARN of the resource or if you're specifying multiple resources, use the `aws:SourceArn` global condition context key with wildcards (\*) for the unknown portions of the ARN. For example, `arn:aws:ssm:*:123456789012:automation-execution/*`.

The following example shows how you can use the `aws:SourceArn` and `aws:SourceAccount` global condition context keys for Automation to prevent the confused deputy problem.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": [
          "ssm.amazonaws.com"
        ]
      },
      "Action": "sts:AssumeRole",
      "Condition": {
        "StringEquals": {
          "aws:SourceAccount": "123456789012"
        },
        "ArnLike": {
          "aws:SourceArn": "arn:aws:ssm:*:123456789012:automation-execution/*"
        }
      }
    }
  ]
}
```

## To modify the role's trust policy

1. Open the IAM console at <https://console.aws.amazon.com/iam/>.

2. In the navigation pane, choose **Roles**.
3. In the list of roles in your account, choose the name of your Automation service role.
4. Choose the **Trust relationships** tab, and then choose **Edit trust relationship**.
5. Edit the trust policy using the `aws:SourceArn` and `aws:SourceAccount` global condition context keys for Automation to prevent the confused deputy problem.
6. Choose **Update Trust Policy** to save your changes.

### **(Optional) Add an Automation inline policy or customer managed policy to invoke other AWS services**

If you run an automation that invokes other AWS services by using an IAM service role, the service role must be configured with permission to invoke those services. This requirement applies to all AWS Automation runbooks (AWS-\* runbooks) such as the `AWS-ConfigureS3BucketLogging`, `AWS-CreateDynamoDBBackup`, and `AWS-RestartEC2Instance` runbooks, to name a few. This requirement also applies to any custom runbooks you create that invoke other AWS services by using actions that call other services. For example, if you use the `aws:executeAwsApi`, `aws:CreateStack`, or `aws:copyImage` actions, to name a few, then you must configure the service role with permission to invoke those services. You can give permissions to other AWS services by adding an IAM inline policy or customer managed policy to the role.

#### **To embed an inline policy for a service role (IAM console)**

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **Roles**.
3. In the list, choose the name of the role that you want to edit.
4. Choose the **Permissions** tab.
5. In the **Add permissions** dropdown, choose **Attach policies** or **Create inline policy**.
6. If you choose **Attach policies**, select the check box next to the policy you want to add and choose **Add permissions**.
7. If you choose **Create inline policy**, choose the **JSON** tab.
8. Enter a JSON Policy document for the AWS services you want to invoke. Here are two example JSON Policy documents.

#### **Amazon S3 PutObject and GetObject Example**

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "s3:PutObject",
        "s3:GetObject"
      ],
      "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/*"
    }
  ]
}
```

### Amazon EC2 CreateSnapshot and DescribeSnapshots Example

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "ec2:CreateSnapshot",
      "Resource": "*"
    },
    {
      "Effect": "Allow",
      "Action": "ec2:DescribeSnapshots",
      "Resource": "*"
    }
  ]
}
```

For details about the IAM policy language, see [IAM JSON Policy Reference](#) in the *IAM User Guide*.

9. When you're finished, choose **Review policy**. The [Policy Validator](#) reports any syntax errors.
10. On the **Review policy** page, enter a **Name** for the policy that you're creating. Review the policy **Summary** to see the permissions that are granted by your policy. Then choose **Create policy** to save your work.

11. After you create an inline policy, it's automatically embedded in your role.

## Task 2: Attach the iam:PassRole policy to your Automation role

Use the following procedure to attach the `iam:PassRole` policy to your Automation service role. This allows the Automation service to pass the role to other services or Systems Manager capabilities when running automations.

### To attach the iam:PassRole policy to your Automation role

1. In the **Summary** page for the role you just created, choose the **Permissions** tab.
2. Choose **Add inline policy**.
3. On the **Create policy** page, choose the **Visual editor** tab.
4. Choose **Service**, and then choose **IAM**.
5. Choose **Select actions**.
6. In the **Filter actions** text box, type **PassRole**, and then choose the **PassRole** option.
7. Choose **Resources**. Verify that **Specific** is selected, and then choose **Add ARN**.
8. In the **Specify ARN for role** field, paste the Automation role ARN that you copied at the end of Task 1. The system populates the **Account** and **Role name with path** fields.

#### Note

If you want the Automation service role to attach an IAM instance profile role to an EC2 instance, then you must add the ARN of the IAM instance profile role. This allows the Automation service role to pass the IAM instance profile role to the target EC2 instance.

9. Choose **Add**.
10. Choose **Review policy**.
11. On the **Review Policy** page, enter a name and then choose **Create Policy**.

## Allowing Automation to adapt to your concurrency needs

By default, Automation allows you to run up to 100 concurrent automations at a time. Automation also provides an optional setting that you can use to adjust your concurrency automation quota

automatically. With this setting, your concurrency automation quota can accommodate up to 500 concurrent automations, depending on available resources.

### Note

If your automation calls API operations, adaptively scaling to your targets can result in throttling exceptions. If recurring throttling exceptions occur when running automations with adaptive concurrency turned on, you might have to request quota increases for the API operation if available.

## To turn on adaptive concurrency using the AWS Management Console

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Automation**.
3. Choose the **Preferences** tab, and then choose **Edit**.
4. Select the check box next to **Enable adaptive concurrency**.
5. Choose **Save**.

## To turn on adaptive concurrency using the command line

- Open the AWS CLI or Tools for Windows PowerShell and run the following command to turn on adaptive concurrency for your account in the requesting Region.

### Linux & macOS

```
aws ssm update-service-setting \  
  --setting-id /ssm/automation/enable-adaptive-concurrency \  
  --setting-value True
```

### Windows

```
aws ssm update-service-setting ^ \  
  --setting-id /ssm/automation/enable-adaptive-concurrency ^ \  
  --setting-value True
```

## PowerShell

```
Update-SSMServiceSetting `
  -SettingId "/ssm/automation/enable-adaptive-concurrency" `
  -SettingValue "True"
```

### Implement change controls for Automation

By default, Automation allows you to use runbooks without date and time constraints. By integrating Automation with Change Calendar, you can implement change controls to all automations in your AWS account. With this setting, AWS Identity and Access Management (IAM) principals in your account can only run automations during the time periods allowed by your change calendar. To learn more about working with Change Calendar, see [Working with Change Calendar](#).

#### To turn on change controls (console)

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Automation**.
3. Choose the **Preferences** tab, and then choose **Edit**.
4. Select the check box next to **Turn on Change Calendar integration**.
5. In the **Choose a change calendar** dropdown list, choose the change calendar that you want Automation to follow.
6. Choose **Save**.

### Run an automated operation powered by Systems Manager Automation

When you run an automation, by default, the automation runs in the context of the user who initiated the automation. This means, for example, if your user has administrator permissions, then the automation runs with administrator permissions and full access to the resources being configured by the automation. As a security best practice, we recommend that you run automation by using an IAM service role that is known in this case as an *assume* role that is configured with the AmazonSSMAutomationRole managed policy. You might need to add additional IAM policies to your assume role to use various runbooks. Using an IAM service role to run automation is called *delegated administration*.

When you use a service role, the automation is allowed to run against the AWS resources, but the user who ran the automation has restricted access (or no access) to those resources. For example, you can configure a service role and use it with Automation to restart one or more Amazon Elastic Compute Cloud (Amazon EC2) instances. Automation is a capability of AWS Systems Manager. The automation restarts the instances, but the service role doesn't give the user permission to access those instances.

You can specify a service role at runtime when you run an automation, or you can create custom runbooks and specify the service role directly in the runbook. If you specify a service role, either at runtime or in a runbook, then the service runs in the context of the specified service role. If you don't specify a service role, then the system creates a temporary session in the context of the user and runs the automation.

 **Note**

You must specify a service role for automation that you expect to run longer than 12 hours. If you start a long-running automation in the context of a user, the user's temporary session expires after 12 hours.

Delegated administration ensures elevated security and control of your AWS resources. It also allows an enhanced auditing experience because actions are being performed against your resources by a central service role instead of multiple IAM accounts.

### **Before you begin**

Before you complete the following procedures, you must create the IAM service role and configure a trust relationship for Automation, a capability of AWS Systems Manager. For more information, see [Task 1: Create a service role for Automation](#).

The following procedures describe how to use the Systems Manager console or your preferred command line tool to run a simple automation.

### **Running a simple automation (console)**

The following procedure describes how to use the Systems Manager console to run a simple automation.

## To run a simple automation

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Automation**, and then choose **Execute automation**.
3. In the **Automation document** list, choose a runbook. Choose one or more options in the **Document categories** pane to filter SSM documents according to their purpose. To view a runbook that you own, choose the **Owned by me** tab. To view a runbook that is shared with your account, choose the **Shared with me** tab. To view all runbooks, choose the **All documents** tab.

### Note

You can view information about a runbook by choosing the runbook name.

4. In the **Document details** section, verify that **Document version** is set to the version that you want to run. The system includes the following version options:
  - **Default version at runtime** – Choose this option if the Automation runbook is updated periodically and a new default version is assigned.
  - **Latest version at runtime** – Choose this option if the Automation runbook is updated periodically, and you want to run the version that was most recently updated.
  - **1 (Default)** – Choose this option to run the first version of the document, which is the default.
5. Choose **Next**.
6. In the **Execution Mode** section, choose **Simple execution**.
7. In the **Input parameters** section, specify the required inputs. Optionally, you can choose an IAM service role from the **AutomationAssumeRole** list.
8. (Optional) Choose a CloudWatch alarm to apply to your automation for monitoring. To attach a CloudWatch alarm to your automation, the IAM principal that starts the automation must have permission for the `iam:createServiceLinkedRole` action. For more information about CloudWatch alarms, see [Using Amazon CloudWatch alarms](#). Note that if your alarm activates, the automation is stopped. If you use AWS CloudTrail, you will see the API call in your trail.
9. Choose **Execute**.

The console displays the status of the automation. If the automation fails to run, see [Troubleshooting Systems Manager Automation](#).

## Running a simple automation (command line)

The following procedure describes how to use the AWS CLI (on Linux or Windows) or AWS Tools for PowerShell to run a simple automation.

### To run a simple automation

1. Install and configure the AWS CLI or the AWS Tools for PowerShell, if you haven't already.

For information, see [Installing or updating the latest version of the AWS CLI](#) and [Installing the AWS Tools for PowerShell](#).

2. Run the following command to start a simple automation. Replace each *example resource placeholder* with your own information.

#### Linux & macOS

```
aws ssm start-automation-execution \  
  --document-name runbook name \  
  --parameters runbook parameters
```

#### Windows

```
aws ssm start-automation-execution ^  
  --document-name runbook name ^  
  --parameters runbook parameters
```

#### PowerShell

```
Start-SSMAutomationExecution `   
  -DocumentName runbook name `   
  -Parameter runbook parameters
```

Here is an example using the runbook `AWS-RestartEC2Instance` to restart the specified EC2 instance.

## Linux & macOS

```
aws ssm start-automation-execution \  
  --document-name "AWS-RestartEC2Instance" \  
  --parameters "InstanceId=i-02573cafcfEXAMPLE"
```

## Windows

```
aws ssm start-automation-execution ^  
  --document-name "AWS-RestartEC2Instance" ^  
  --parameters "InstanceId=i-02573cafcfEXAMPLE"
```

## PowerShell

```
Start-SSMAutomationExecution `\  
  -DocumentName AWS-RestartEC2Instance `\  
  -Parameter @{"InstanceId"="i-02573cafcfEXAMPLE"}
```

The system returns information like the following.

## Linux & macOS

```
{  
  "AutomationExecutionId": "4105a4fc-f944-11e6-9d32-0123456789ab"  
}
```

## Windows

```
{  
  "AutomationExecutionId": "4105a4fc-f944-11e6-9d32-0123456789ab"  
}
```

## PowerShell

```
4105a4fc-f944-11e6-9d32-0123456789ab
```

3. Run the following command to retrieve the status of the automation.

## Linux & macOS

```
aws ssm describe-automation-executions \  
  --filter "Key=ExecutionId,Values=4105a4fc-f944-11e6-9d32-0123456789ab"
```

## Windows

```
aws ssm describe-automation-executions ^  
  --filter "Key=ExecutionId,Values=4105a4fc-f944-11e6-9d32-0123456789ab"
```

## PowerShell

```
Get-SSMAutomationExecutionList | `  
  Where {$_.AutomationExecutionId -eq "4105a4fc-f944-11e6-9d32-0123456789ab"}
```

The system returns information like the following.

## Linux & macOS

```
{  
  "AutomationExecutionMetadataList": [  
    {  
      "AutomationExecutionStatus": "InProgress",  
      "CurrentStepName": "stopInstances",  
      "Outputs": {},  
      "DocumentName": "AWS-RestartEC2Instance",  
      "AutomationExecutionId": "4105a4fc-f944-11e6-9d32-0123456789ab",  
      "DocumentVersion": "1",  
      "ResolvedTargets": {  
        "ParameterValues": [],  
        "Truncated": false  
      },  
      "AutomationType": "Local",  
      "Mode": "Auto",  
      "ExecutionStartTime": 1564600648.159,  
      "CurrentAction": "aws:changeInstanceState",  
      "ExecutedBy": "arn:aws:sts::123456789012:assumed-role/Administrator/  
Admin",  
      "LogFile": "",  
      "Targets": []  
    }  
  ]  
}
```

```

    }
  ]
}

```

## Windows

```

{
  "AutomationExecutionMetadataList": [
    {
      "AutomationExecutionStatus": "InProgress",
      "CurrentStepName": "stopInstances",
      "Outputs": {},
      "DocumentName": "AWS-RestartEC2Instance",
      "AutomationExecutionId": "4105a4fc-f944-11e6-9d32-0123456789ab",
      "DocumentVersion": "1",
      "ResolvedTargets": {
        "ParameterValues": [],
        "Truncated": false
      },

```

## Run an automation that requires approvals

The following procedures describe how to use the AWS Systems Manager console and AWS Command Line Interface (AWS CLI) to run an automation with approvals using simple execution. The automation uses the automation action `aws:approve`, which temporarily pauses the automation until the designated principals either approve or deny the action. The automation runs in the context of the current user. This means that you don't need to configure additional IAM permissions as long as you have permission to use the runbook, and any actions called by the runbook. If you have administrator permissions in IAM, then you already have permission to use this runbook.

### Before you begin

In addition to the standard inputs required by the runbook, the `aws:approve` action requires the following two parameters:

- A list of approvers. The list of approvers must contain at least one approver in the form of a user name or a user ARN. If multiple approvers are provided, a corresponding minimum approval count must also be specified within the runbook.
- An Amazon Simple Notification Service (Amazon SNS) topic ARN. The Amazon SNS topic name must start with `Automation`.

This procedure assumes that you have already created an Amazon SNS topic, which is required to deliver the approval request. For information, see [Create a Topic](#) in the *Amazon Simple Notification Service Developer Guide*.

## Running an automation with approvers (console)

### To run an automation with approvers

The following procedure describes how to use the Systems Manager console to run an automation with approvers.

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Automation**, and then choose **Execute automation**.
3. In the **Automation document** list, choose a runbook. Choose one or more options in the **Document categories** pane to filter SSM documents according to their purpose. To view a runbook that you own, choose the **Owned by me** tab. To view a runbook that is shared with your account, choose the **Shared with me** tab. To view all runbooks, choose the **All documents** tab.

#### Note

You can view information about a runbook by choosing the runbook name.

4. In the **Document details** section, verify that **Document version** is set to the version that you want to run. The system includes the following version options:
  - **Default version at runtime** – Choose this option if the Automation runbook is updated periodically and a new default version is assigned.
  - **Latest version at runtime** – Choose this option if the Automation runbook is updated periodically, and you want to run the version that was most recently updated.
  - **1 (Default)** – Choose this option to run the first version of the document, which is the default.
5. Choose **Next**.
6. On the **Execute automation document** page, choose **Simple execution**.
7. In the **Input parameters** section, specify the required input parameters.

For example, if you chose the **AWS-StartEC2InstanceWithApproval** runbook, then you must specify or choose instance IDs for the **InstanceId** parameter.

8. In the **Approvers** section, specify the user names or user ARNs of approvers for the automation action.
9. In the **SNSTopicARN** section, specify the SNS topic ARN to use for sending approval notification. The SNS topic name must start with **Automation**.
10. Optionally, you can choose an IAM service role from the **AutomationAssumeRole** list. If you're targeting more than 100 accounts and Regions, you must specify the `AWS-SystemsManager-AutomationAdministrationRole`.
11. Choose **Execute automation**.

The specified approver receives an Amazon SNS notification with details to approve or reject the automation. This approval action is valid for 7 days from the date of issue and can be issued using the Systems Manager console or the AWS Command Line Interface (AWS CLI).

If you chose to approve the automation, the automation continues to run the steps included in the specified runbook. The console displays the status of the automation. If the automation fails to run, see [Troubleshooting Systems Manager Automation](#).

### To approve or deny an automation

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Automation**, and then select the automation that was run in the previous procedure.
3. Choose **Actions** and then choose **Approve/Deny**.
4. Choose to **Approve** or **Deny** and optionally provide a comment.
5. Choose **Submit**.

### Running an automation with approvers (command line)

The following procedure describes how to use the AWS CLI (on Linux or Windows) or AWS Tools for PowerShell to run an automation with approvers.

## To run an automation with approvers

1. Install and configure the AWS CLI or the AWS Tools for PowerShell, if you haven't already.

For information, see [Installing or updating the latest version of the AWS CLI](#) and [Installing the AWS Tools for PowerShell](#).

2. Run the following command to run an automation with approvers. Replace each *example resource placeholder* with your own information. In the document name section, specify a runbook that includes the automation action, `aws:approve`.

For Approvers, specify the user names or user ARNs of approvers for the action. For SNSTopic, specify the SNS topic ARN to use to send approval notification. The Amazon SNS topic name must start with `Automation`.

### Note

The specific names of the parameter values for approvers and the SNS topic depend on the values specified within the runbook you choose.

### Linux & macOS

```
aws ssm start-automation-execution \  
  --document-name "AWS-StartEC2InstanceWithApproval" \  
  --parameters  
  "InstanceId=i-02573cafcfEXAMPLE,Approvers=arn:aws:iam::123456789012:role/  
Administrator,SNSTopicArn=arn:aws:sns:region:123456789012:AutomationApproval"
```

### Windows

```
aws ssm start-automation-execution ^  
  --document-name "AWS-StartEC2InstanceWithApproval" ^  
  --parameters  
  "InstanceId=i-02573cafcfEXAMPLE,Approvers=arn:aws:iam::123456789012:role/  
Administrator,SNSTopicArn=arn:aws:sns:region:123456789012:AutomationApproval"
```

### PowerShell

```
Start-SSMAutomationExecution `
```

```
-DocumentName AWS-StartEC2InstanceWithApproval `
-Parameters @{
    "InstanceId"="i-02573cafcfEXAMPLE"
    "Approvers"="arn:aws:iam::123456789012:role/Administrator"
    "SNSTopicArn"="arn:aws:sns:region:123456789012:AutomationApproval"
}
```

The system returns information like the following.

### Linux & macOS

```
{
  "AutomationExecutionId": "df325c6d-b1b1-4aa0-8003-6cb7338213c6"
}
```

### Windows

```
{
  "AutomationExecutionId": "df325c6d-b1b1-4aa0-8003-6cb7338213c6"
}
```

### PowerShell

```
df325c6d-b1b1-4aa0-8003-6cb7338213c6
```

## To approve an automation

- Run the following command to approve an automation. Replace each *example resource placeholder* with your own information.

### Linux & macOS

```
aws ssm send-automation-signal \
  --automation-execution-id "df325c6d-b1b1-4aa0-8003-6cb7338213c6" \
  --signal-type "Approve" \
  --payload "Comment=your comments"
```

## Windows

```
aws ssm send-automation-signal ^
  --automation-execution-id "df325c6d-b1b1-4aa0-8003-6cb7338213c6" ^
  --signal-type "Approve" ^
  --payload "Comment=your comments"
```

## PowerShell

```
Send-SSMAutomationSignal `
  -AutomationExecutionId df325c6d-b1b1-4aa0-8003-6cb7338213c6 `
  -SignalType Approve `
  -Payload @{"Comment"="your comments"}
```

There is no output if the command succeeds.

## To deny an automation

- Run the following command to deny an automation. Replace each *example resource placeholder* with your own information.

## Linux & macOS

```
aws ssm send-automation-signal \
  --automation-execution-id "df325c6d-b1b1-4aa0-8003-6cb7338213c6" \
  --signal-type "Deny" \
  --payload "Comment=your comments"
```

## Windows

```
aws ssm send-automation-signal ^
  --automation-execution-id "df325c6d-b1b1-4aa0-8003-6cb7338213c6" ^
  --signal-type "Deny" ^
  --payload "Comment=your comments"
```

## PowerShell

```
Send-SSMAutomationSignal `
```

```
-AutomationExecutionId df325c6d-b1b1-4aa0-8003-6cb7338213c6 `
-SignalType Deny `
-Payload @{"Comment"="your comments"}
```

There is no output if the command succeeds.

## Run automated operations at scale

With AWS Systems Manager Automation, you can run automations on a fleet of AWS resources by using *targets*. Additionally, you can control the deployment of the automation across your fleet by specifying a concurrency value and an error threshold. The concurrency and error threshold features are collectively called *rate controls*. The concurrency value determines how many resources are allowed to run the automation simultaneously. Automation also provides an adaptive concurrency mode you can opt in to. Adaptive concurrency automatically scales your automation quota from 100 concurrently running automations up to 500. An error threshold determines how many automations are allowed to fail before Systems Manager stops sending the automation to other resources.

For more information about concurrency and error thresholds, see [Control automations at scale](#). For more information about targets, see [Mapping targets for an automation](#).

The following procedures show you how to turn on adaptive concurrency, and how to run an automation with targets and rate controls by using the Systems Manager console and AWS Command Line Interface (AWS CLI).

### Running an automation with targets and rate controls (console)

The following procedure describes how to use the Systems Manager console to run an automation with targets and rate controls.

#### To run an automation with targets and rate controls

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Automation**, and then choose **Execute automation**.
3. In the **Automation document** list, choose a runbook. Choose one or more options in the **Document categories** pane to filter SSM documents according to their purpose. To view a runbook that you own, choose the **Owned by me** tab. To view a runbook that is shared with

your account, choose the **Shared with me** tab. To view all runbooks, choose the **All documents** tab.

 **Note**

You can view information about a runbook by choosing the runbook name.

4. In the **Document details** section, verify that **Document version** is set to the version that you want to run. The system includes the following version options:
  - **Default version at runtime** – Choose this option if the Automation runbook is updated periodically and a new default version is assigned.
  - **Latest version at runtime** – Choose this option if the Automation runbook is updated periodically, and you want to run the version that was most recently updated.
  - **1 (Default)** – Choose this option to run the first version of the document, which is the default.
5. Choose **Next**.
6. In the **Execution Mode** section, choose **Rate Control**. You must use this mode or **Multi-account and Region** if you want to use targets and rate controls.
7. In the **Targets** section, choose how you want to target the AWS resources where you want to run the Automation. These options are required.
  - a. Use the **Parameter** list to choose a parameter. The items in the **Parameter** list are determined by the parameters in the Automation runbook that you selected at the start of this procedure. By choosing a parameter you define the type of resource on which the Automation workflow runs.
  - b. Use the **Targets** list to choose how you want to target resources.
    - i. If you chose to target resources by using parameter values, then enter the parameter value for the parameter you chose in the **Input parameters** section.
    - ii. If you chose to target resources by using AWS Resource Groups, then choose the name of the group from the **Resource Group** list.
    - iii. If you chose to target resources by using tags, then enter the tag key and (optionally) the tag value in the fields provided. Choose **Add**.
    - iv. If you want to run an Automation runbook on all instances in the current AWS account and AWS Region, then choose **All instances**.

8. In the **Input parameters** section, specify the required inputs. Optionally, you can choose an IAM service role from the **AutomationAssumeRole** list.

 **Note**

You might not need to choose some of the options in the **Input parameters** section. This is because you targeted resources by using tags or a resource group. For example, if you chose the `AWS-RestartEC2Instance` runbook, then you don't need to specify or choose instance IDs in the **Input parameters** section. The Automation execution locates the instances to restart by using the tags or resource group you specified.

9. Use the options in the **Rate control** section to restrict the number of AWS resources that can run the Automation within each account-Region pair.

In the **Concurrency** section, choose an option:

- Choose **targets** to enter an absolute number of targets that can run the Automation workflow simultaneously.
- Choose **percentage** to enter a percentage of the target set that can run the Automation workflow simultaneously.

10. In the **Error threshold** section, choose an option:

- Choose **errors** to enter an absolute number of errors allowed before Automation stops sending the workflow to other resources.
- Choose **percentage** to enter a percentage of errors allowed before Automation stops sending the workflow to other resources.

11. (Optional) Choose a CloudWatch alarm to apply to your automation for monitoring. To attach a CloudWatch alarm to your automation, the IAM principal that starts the automation must have permission for the `iam:createServiceLinkedRole` action. For more information about CloudWatch alarms, see [Using Amazon CloudWatch alarms](#). Note that if your alarm activates, the automation is stopped. If you use AWS CloudTrail, you will see the API call in your trail.

12. Choose **Execute**.

To view automations started by your rate control automation, in the navigation pane, choose Automation, and then select **Show child automations**.

## Running an automation with targets and rate controls (command line)

The following procedure describes how to use the AWS CLI (on Linux or Windows) or AWS Tools for PowerShell to run an automation with targets and rate controls.

### To run an automation with targets and rate controls

1. Install and configure the AWS CLI or the AWS Tools for PowerShell, if you haven't already.

For information, see [Installing or updating the latest version of the AWS CLI](#) and [Installing the AWS Tools for PowerShell](#).

2. Run the following command to view a list of documents.

#### Linux & macOS

```
aws ssm list-documents
```

#### Windows

```
aws ssm list-documents
```

#### PowerShell

```
Get-SSMDocumentList
```

Note the name of the runbook that you want to use.

3. Run the following command to view details about the runbook. Replace the *runbook name* with the name of the runbook whose details you want to view. Also, note a parameter name (for example, InstanceId) that you want to use for the `--target-parameter-name` option. This parameter determines the type of resource on which the automation runs.

#### Linux & macOS

```
aws ssm describe-document \  
  --name runbook name
```

## Windows

```
aws ssm describe-document ^
  --name runbook name
```

## PowerShell

```
Get-SSMDocumentDescription `
  -Name runbook name
```

4. Create a command that uses the targets and rate control options you want to run. Replace each *example resource placeholder* with your own information.

### Targeting using tags

## Linux & macOS

```
aws ssm start-automation-execution \
  --document-name runbook name \
  --targets Key=tag:key name,Values=value \
  --target-parameter-name parameter name \
  --parameters "input parameter name=input parameter value,input parameter 2  
name=input parameter 2 value" \
  --max-concurrency 10 \
  --max-errors 25%
```

## Windows

```
aws ssm start-automation-execution ^
  --document-name runbook name ^
  --targets Key=tag:key name,Values=value ^
  --target-parameter-name parameter name ^
  --parameters "input parameter name=input parameter value,input parameter 2  
name=input parameter 2 value" ^
  --max-concurrency 10 ^
  --max-errors 25%
```

## PowerShell

```
$Targets = New-Object Amazon.SimpleSystemsManagement.Model.Target
```

```

$Targets.Key = "tag:key name"
$Targets.Values = "value"

Start-SSMAutomationExecution `
  DocumentName "runbook name" `
  -Targets $Targets `
  -TargetParameterName "parameter name" `
  -Parameter @{"input parameter name"="input parameter value";"input parameter
  2 name"="input parameter 2 value"} `
  -MaxConcurrency "10" `
  -MaxError "25%"

```

## Targeting using parameter values

### Linux & macOS

```

aws ssm start-automation-execution \
  --document-name runbook name \
  --targets Key=ParameterValues,Values=value,value 2,value 3 \
  --target-parameter-name parameter name \
  --parameters "input parameter name=input parameter value" \
  --max-concurrency 10 \
  --max-errors 25%

```

### Windows

```

aws ssm start-automation-execution ^
  --document-name runbook name ^
  --targets Key=ParameterValues,Values=value,value 2,value 3 ^
  --target-parameter-name parameter name ^
  --parameters "input parameter name=input parameter value" ^
  --max-concurrency 10 ^
  --max-errors 25%

```

### PowerShell

```

$Targets = New-Object Amazon.SimpleSystemsManagement.Model.Target
$Targets.Key = "ParameterValues"
$Targets.Values = "value","value 2","value 3"

Start-SSMAutomationExecution `

```

```
-DocumentName "runbook name" `
-Targets $Targets `
-TargetParameterName "parameter name" `
-Parameter @{"input parameter name"="input parameter value"} `
-MaxConcurrency "10" `
-MaxError "25%"
```

## Targeting using AWS Resource Groups

### Linux & macOS

```
aws ssm start-automation-execution \
  --document-name runbook name \
  --targets Key=ResourceGroup,Values=Resource group name \
  --target-parameter-name parameter name \
  --parameters "input parameter name=input parameter value" \
  --max-concurrency 10 \
  --max-errors 25%
```

### Windows

```
aws ssm start-automation-execution ^
  --document-name runbook name ^
  --targets Key=ResourceGroup,Values=Resource group name ^
  --target-parameter-name parameter name ^
  --parameters "input parameter name=input parameter value" ^
  --max-concurrency 10 ^
  --max-errors 25%
```

### PowerShell

```
$Targets = New-Object Amazon.SimpleSystemsManagement.Model.Target
$Targets.Key = "ResourceGroup"
$Targets.Values = "Resource group name"

Start-SSMAutomationExecution `
  -DocumentName "runbook name" `
  -Targets $Targets `
  -TargetParameterName "parameter name" `
  -Parameter @{"input parameter name"="input parameter value"} `
  -MaxConcurrency "10" `
```

```
-MaxError "25%"
```

## Targeting all Amazon EC2 instances in the current AWS account and AWS Region

### Linux & macOS

```
aws ssm start-automation-execution \
  --document-name runbook name \
  --targets "Key=AWS::EC2::Instance,Values=*" \
  --target-parameter-name instanceId \
  --parameters "input parameter name=input parameter value" \
  --max-concurrency 10 \
  --max-errors 25%
```

### Windows

```
aws ssm start-automation-execution ^
  --document-name runbook name ^
  --targets Key=AWS::EC2::Instance,Values=* ^
  --target-parameter-name instanceId ^
  --parameters "input parameter name=input parameter value" ^
  --max-concurrency 10 ^
  --max-errors 25%
```

### PowerShell

```
$Targets = New-Object Amazon.SimpleSystemsManagement.Model.Target
$Targets.Key = "AWS::EC2::Instance"
$Targets.Values = "*"

Start-SSMAutomationExecution `
  -DocumentName "runbook name" `
  -Targets $Targets `
  -TargetParameterName "instanceId" `
  -Parameter @{"input parameter name"="input parameter value"} `
  -MaxConcurrency "10" `
  -MaxError "25%"
```

The command returns an execution ID. Copy this ID to the clipboard. You can use this ID to view the status of the automation.

### Linux & macOS

```
{
  "AutomationExecutionId": "a4a3c0e9-7efd-462a-8594-01234EXAMPLE"
}
```

### Windows

```
{
  "AutomationExecutionId": "a4a3c0e9-7efd-462a-8594-01234EXAMPLE"
}
```

### PowerShell

```
a4a3c0e9-7efd-462a-8594-01234EXAMPLE
```

5. Run the following command to view the automation. Replace each *automation execution ID* with your own information.

### Linux & macOS

```
aws ssm describe-automation-executions \
  --filter Key=ExecutionId,Values=automation execution ID
```

### Windows

```
aws ssm describe-automation-executions ^
  --filter Key=ExecutionId,Values=automation execution ID
```

### PowerShell

```
Get-SSMAutomationExecutionList | `
  Where {$_.AutomationExecutionId -eq "automation execution ID"}
```

- To view details about the automation progress, run the following command. Replace each *automation execution ID* with your own information.

### Linux & macOS

```
aws ssm get-automation-execution \  
  --automation-execution-id automation execution ID
```

### Windows

```
aws ssm get-automation-execution ^  
  --automation-execution-id automation execution ID
```

### PowerShell

```
Get-SSMAutomationExecution `  
  -AutomationExecutionId automation execution ID
```

The system returns information like the following.

### Linux & macOS

```
{  
  "AutomationExecution": {

```

### Note

You can also monitor the status of the automation in the console. In the **Automation executions** list, choose the automation you just ran and then choose the **Execution steps** tab. This tab shows the status of the automation actions.

## Mapping targets for an automation

Use the `Targets` parameter to quickly define which resources are targeted by an automation. For example, if you want to run an automation that restarts your managed instances, then instead of manually selecting dozens of instance IDs in the console or typing them in a command, you can target instances by specifying Amazon Elastic Compute Cloud (Amazon EC2) tags with the `Targets` parameter.

When you run an automation that uses a target, AWS Systems Manager creates a child automation for each target. For example, if you target Amazon Elastic Block Store (Amazon EBS) volumes by specifying tags, and those tags resolve to 100 Amazon EBS volumes, then Systems Manager creates 100 child automations. The parent automation is complete when all child automations reach a final state.

### Note

Any `input parameters` that you specify at runtime (either in the **Input parameters** section of the console or by using the `parameters` option from the command line) are automatically processed by all child automations.

You can target resources for an automation by using tags, Resource Groups, and parameter values. Additionally, you can use the `TargetMaps` option to target multiple parameter values from the command line or a file. The following section describes each of these targeting options in more detail.

## Targeting a tag

You can specify a single tag as the target of an automation. Many AWS resources support tags, including Amazon Elastic Compute Cloud (Amazon EC2) and Amazon Relational Database Service (Amazon RDS) instances, Amazon Elastic Block Store (Amazon EBS) volumes and snapshots, Resource Groups, and Amazon Simple Storage Service (Amazon S3) buckets, to name a few. You can quickly run automation on your AWS resources by targeting a tag. A tag is a key-value pair, such as `Operating_System:Linux` or `Department:Finance`. If you assign a specific name to a resource, then you can also use the word "Name" as a key, and the name of the resource as the value.

When you specify a tag as the target for an automation, you also specify a target parameter. The target parameter uses the `TargetParameterName` option. By choosing a target parameter, you define the type of resource on which the automation runs. The target parameter you specify with the tag must be a valid parameter defined in the runbook. For example, if you want to target dozens of EC2 instances by using tags, then choose the `InstanceId` target parameter. By choosing this parameter, you define *instances* as the resource type for the automation. When creating a custom runbook you must specify the **Target type** as `/AWS::EC2::Instance` to ensure only instances are used. Otherwise, all resources with the same tag will be targeted. When targeting instances with a tag, terminated instances might be included.

The following screenshot uses the `AWS-DetachEBSVolume` runbook. The logical target parameter is `VolumeId`.

**Targets**  
Select the targets on which the automation document will run.

---

**Parameter**  
Choose the parameter that will define how your automation will branch out.

Volumeld ▼

---

**Targets**

Tags ▼

---

**Tags**  
Specify a tag key/value pair.

Finance  Test Env

Enter a tag key and optional value applied to the instances you want to target, and then choose **Add**.

The `AWS-DetachEBSVolume` runbook also includes a special property called **Target type**, which is set to `/AWS::EC2::Volume`. This means that if the tag-key pair `Finance:TestEnv` returns different types of resources (for example, EC2 instances, Amazon EBS volumes, Amazon EBS snapshots) then only Amazon EBS volumes will be used.

### Important

Target parameter names are case sensitive. If you run automations by using either the AWS Command Line Interface (AWS CLI) or AWS Tools for Windows PowerShell, then you must enter the target parameter name exactly as it's defined in the runbook. If you don't, the system returns an `InvalidAutomationExecutionParametersException` error. You can use the [DescribeDocument](#) API operation to see information about the available target parameters in a specific runbook. Following is an example AWS CLI command that provides information about the `AWS-DeleteSnapshot` document.

```
aws ssm describe-document \
  --name AWS-DeleteSnapshot
```

Here are some example AWS CLI commands that target resources by using a tag.

### Example 1: Targeting a tag using a key-value pair to restart Amazon EC2 instances

This example restarts all Amazon EC2 instances that are tagged with a key of *Department* and a value of *HumanResources*. The target parameter uses the *InstanceId* parameter from the runbook. The example uses an additional parameter to run the automation by using an Automation service role (also called an *assume role*).

```
aws ssm start-automation-execution \  
  --document-name AWS-RestartEC2Instance \  
  --targets Key=tag:Department,Values=HumanResources \  
  --target-parameter-name InstanceId \  
  --parameters "AutomationAssumeRole=arn:aws:iam::111122223333:role/  
AutomationServiceRole"
```

### Example 2: Targeting a tag using a key-value pair to delete Amazon EBS snapshots

The following example uses the *AWS-DeleteSnapshot* runbook to delete all snapshots with a key of *Name* and a value of *January2018Backups*. The target parameter uses the *VolumeId* parameter.

```
aws ssm start-automation-execution \  
  --document-name AWS-DeleteSnapshot \  
  --targets Key=tag:Name,Values=January2018Backups \  
  --target-parameter-name VolumeId
```

### Targeting AWS Resource Groups

You can specify a single AWS resource group as the target of an automation. Systems Manager creates a child automation for every object in the target Resource Group.

For example, say that one of your Resource Groups is named *PatchedAMIs*. This Resource Group includes a list of 25 Windows Amazon Machine Images (AMIs) that are routinely patched. If you run an automation that uses the *AWS-CreateManagedWindowsInstance* runbook and target this Resource Group, then Systems Manager creates a child automation for each of the 25 AMIs. This means, that by targeting the *PatchedAMIs* Resource Group, the automation creates 25 instances from a list of patched AMIs. The parent automation is complete when all child automations complete processing or reach a final state.

The following AWS CLI command applies to the *PatchAMIs* Resource Group example. The command takes the *Amild* parameter for the `--target-parameter-name` option. The command doesn't include an additional parameter defining which type of instance to create from each AMI. The *AWS-CreateManagedWindowsInstance* runbook defaults to the *t2.medium* instance type, so this command would create 25 *t2.medium* Amazon EC2 instances for Windows Server.

```
aws ssm start-automation-execution \
  --document-name AWS-CreateManagedWindowsInstance \
  --targets Key=ResourceGroup,Values=PatchedAMIs \
  --target-parameter-name AmiId
```

The following console example uses a Resource Group called t2-micro-instances.

**Targets**  
Select the targets on which the automation document will run.

---

**Parameter**  
Choose the parameter that will define how your automation will branch out.

AmiId ▼

**Targets**

Resource Group ▼

**Resource group**

🔍 t2-micro-instances ✕

## Targeting parameter values

You can also target a parameter value. You enter `ParameterValues` as the key and then enter the specific resource value where you want the automation to run. If you specify multiple values, Systems Manager runs a child automation on each value specified.

For example, say that your runbook includes an **InstanceID** parameter. If you target the values of the **InstanceID** parameter when you run the Automation, then Systems Manager runs a child automation for each instance ID value specified. The parent automation is complete when the automation finishes running each specified instance, or if the automation fails. You can target a maximum of 50 parameter values.

The following example uses the `AWS-CreateImage` runbook. The target parameter name specified is `InstanceId`. The key uses `ParameterValues`. The values are two Amazon EC2 instance IDs. This command creates an automation for each instance, which produces an AMI from each instance.

```
aws ssm start-automation-execution
  --document-name AWS-CreateImage \
  --target-parameter-name InstanceId \
  --targets Key=ParameterValues,Values=i-02573cafcfEXAMPLE,i-0471e04240EXAMPLE
```

**Note**

AutomationAssumeRole isn't a valid parameter. Don't choose this item when running automation that target a parameter value.

## Targeting parameter value maps

The TargetMaps option expands your ability to target ParameterValues. You can enter an array of parameter values by using TargetMaps at the command line. You can specify a maximum of 50 parameter values at the command line. If you want to run commands that specify more than 50 parameter values, then you can enter the values in a JSON file. You can then call the file from the command line.

**Note**

The TargetMaps option isn't supported in the console.

Use the following format to specify multiple parameter values by using the TargetMaps option in a command. Replace each *example resource placeholder* with your own information.

```
aws ssm start-automation-execution \  
  --document-name runbook name \  
  --target-maps "parameter=value, parameter 2=value, parameter 3=value" "parameter 4=value, parameter 5=value, parameter 6=value"
```

If you want to enter more than 50 parameter values for the TargetMaps option, then specify the values in a file by using the following JSON format. Using a JSON file also improves readability when providing multiple parameter values.

```
[  
  
  {"parameter": "value", "parameter 2": "value", "parameter 3": "value"},  
  
  {"parameter 4": "value", "parameter 5": "value", "parameter 6": "value"}  
  
]
```

Save the file with a .json file extension. You can call the file by using the following command. Replace each *example resource placeholder* with your own information.

```
aws ssm start-automation-execution \
  --document-name runbook name \
  --parameters input parameters \
  --target-maps path to file/file name.json
```

You can also download the file from an Amazon Simple Storage Service (Amazon S3) bucket, as long as you have permission to read data from the bucket. Use the following command format. Replace each *example resource placeholder* with your own information.

```
aws ssm start-automation-execution \
  --document-name runbook name \
  --target-maps http://amzn-s3-demo-bucket.s3.amazonaws.com/file\_name.json
```

Here is an example scenario to help you understand the TargetMaps option. In this scenario, a user wants to create Amazon EC2 instances of different types from different AMIs. To perform this task, the user creates a runbook named AMI\_Testing. This runbook defines two input parameters: `instanceType` and `imageId`.

```
{
  "description": "AMI Testing",
  "schemaVersion": "0.3",
  "assumeRole": "{{assumeRole}}",
  "parameters": {
    "assumeRole": {
      "type": "String",
      "description": "Role under which to run the automation",
      "default": ""
    },
    "instanceType": {
      "type": "String",
      "description": "Type of EC2 Instance to launch for this test"
    },
    "imageId": {
      "type": "String",
      "description": "Source AMI id from which to run instance"
    }
  },
  "mainSteps": [
```

```
{
  "name": "runInstances",
  "action": "aws:runInstances",
  "maxAttempts": 1,
  "onFailure": "Abort",
  "inputs": {
    "ImageId": "{{imageId}}",
    "InstanceType": "{{instanceType}}",
    "MinInstanceCount": 1,
    "MaxInstanceCount": 1
  }
},
"outputs": [
  "runInstances.InstanceIds"
]
```

The user then specifies the following target parameter values in a file named `AMI_instance_types.json`.

```
[
  {
    "instanceType" : ["t2.micro"],
    "imageId" : ["ami-b70554c8"]
  },
  {
    "instanceType" : ["t2.small"],
    "imageId" : ["ami-b70554c8"]
  },
  {
    "instanceType" : ["t2.medium"],
    "imageId" : ["ami-cfe4b2b0"]
  },
  {
    "instanceType" : ["t2.medium"],
    "imageId" : ["ami-cfe4b2b0"]
  },
  {
    "instanceType" : ["t2.medium"],
    "imageId" : ["ami-cfe4b2b0"]
  }
]
```

The user can run the automation and create the five EC2 instances defined in `AMI_instance_types.json` by running the following command.

```
aws ssm start-automation-execution \  
  --document-name AMI_Testing \  
  --target-parameter-name imageId \  
  --target-maps file:///home/TestUser/workspace/runinstances/AMI_instance_types.json
```

## Targeting all Amazon EC2 instances

You can run an automation on all Amazon EC2 instances in the current AWS account and AWS Region by choosing **All instances** in the **Targets** list. For example, if you want to restart all Amazon EC2 instances your AWS account and the current AWS Region, you can choose the **AWS-RestartEC2Instance** runbook and then choose **All instances** from the **Targets** list.

The screenshot shows a configuration interface for an automation document. It has a title "Targets" and a subtitle "Select the targets on which the automation document will run." Below this, there are three sections:

- Parameter:** A dropdown menu with "Instanceld" selected.
- Targets:** A dropdown menu with "All instances" selected. This dropdown is highlighted with a red box.
- Instance:** A text input field containing an asterisk (\*). This field is highlighted with a red box and is grayed out, indicating it is disabled.

After you choose **All instances**, Systems Manager populates the **Instance** field with an asterisk (\*) and makes the field unavailable for changes (the field is grayed out). Systems Manager also makes the **Instanceld** field in the **Input parameters** field unavailable for changes. Making these fields unavailable for changes is expected behavior if you choose to target all instances.

## Control automations at scale

You can control the deployment of an automation across a fleet of AWS resources by specifying a concurrency value and an error threshold. Concurrency and error threshold are collectively called *rate controls*.

## Concurrency

Use **Concurrency** to specify how many resources are allowed to run an automation simultaneously. Concurrency helps to limit the impact or downtime on your resources when processing an automation. You can specify either an absolute number of resources, for example 20, or a percentage of the target set, for example 10%.

The queueing system delivers the automation to a single resource and waits until the initial invocation is complete before sending the automation to two more resources. The system exponentially sends the automation to more resources until the concurrency value is met.

## Error thresholds

Use an error threshold to specify how many automations are allowed to fail before AWS Systems Manager stops sending the automation to other resources. You can specify either an absolute number of errors, for example 10, or a percentage of the target set, for example 10%.

If you specify an absolute number of 3 errors, for example, the system stops running the automation when the fourth error is received. If you specify 0, then the system stops running the automation on additional targets after the first error result is returned.

If you send an automation to, for example, 50 instances and set the error threshold to 10%, then the system stops sending the command to additional instances when the fifth error is received. Invocations that are already running an automation when an error threshold is reached are allowed to be completed, but some of these automations might fail as well. If you need to ensure that there won't be more errors than the number specified for the error threshold, then set the **Concurrency** value to 1 so that automations proceed one at a time.

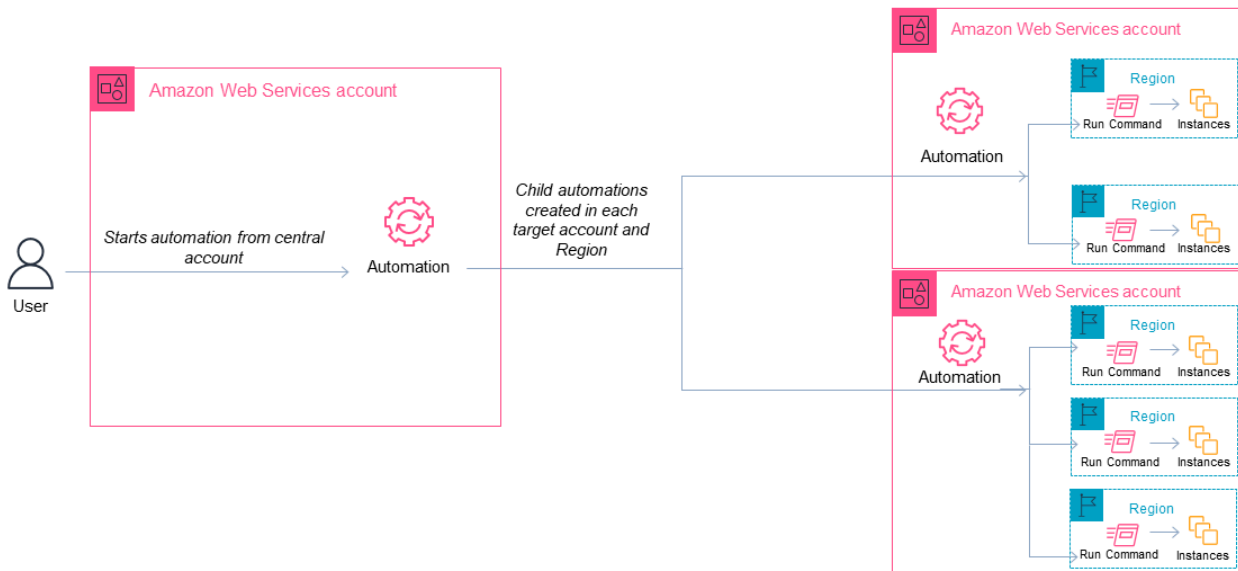

## Running automations in multiple AWS Regions and accounts

You can run AWS Systems Manager automations across multiple AWS Regions and AWS accounts or AWS Organizations organizational units (OUs) from a central account. Automation is a capability of AWS Systems Manager. Running automations in multiple Regions and accounts or OUs reduces the time required to administer your AWS resources while enhancing the security of your computing environment.

For example, you can do the following by using automation runbooks:

- Implement patching and security updates centrally.
- Remediate compliance drift on VPC configurations or Amazon S3 bucket policies.
- Manage resources, such as Amazon Elastic Compute Cloud (Amazon EC2) EC2 instances, at scale.

The following diagram shows an example of a user who is running the AWS-RestartEC2Instances runbook in multiple Regions and accounts from a central account. The automation locates the instances by using the specified tags in the targeted Regions and accounts.

## Choose a central account for Automation

If you want to run automations across OUs, the central account must have permissions to list all of the accounts in the OUs. This is only possible from a delegated administrator account, or the management account of the organization. We recommend that you follow AWS Organizations best practices and use a delegated administrator account. For more information about AWS Organizations best practices, see [Best practices for the management account](#) in the *AWS Organizations User Guide*. To create a delegated administrator account for Systems Manager, you can use the `register-delegated-administrator` command with the AWS CLI as shown in the following example.

```
aws organizations register-delegated-administrator \
  --account-id delegated admin account ID \
  --service-principal ssm.amazonaws.com
```

If you want to run automations across multiple accounts that are not managed by AWS Organizations, we recommend creating a dedicated account for automation management. Running

all cross-account automations from a dedicated account simplifies IAM permissions management, troubleshooting efforts, and creates a layer of separation between operations and administration. This approach is also recommended if you use AWS Organizations, but only want to target individual accounts and not OUs.

## How running automations works

Running automations across multiple Regions and accounts or OUs works as follows:

1. Sign in to the account that you want to configure as the Automation central account.
2. Use the [Setting up management account permissions for multi-Region and multi-account automation](#) procedure in this topic to create the following IAM roles:
  - **AWS-SystemsManager-AutomationAdministrationRole** - This role gives the user permission to run automations in multiple accounts and OUs.
  - **AWS-SystemsManager-AutomationExecutionRole** - This role gives the user permission to run automations in the targeted accounts.
3. Choose the runbook, Regions, and accounts or OUs where you want to run the automation.

### Note

Be sure that the target OU contains the desired accounts. If you choose a custom runbook, the runbook must be shared with all of the target accounts. For information about sharing runbooks, see [Sharing SSM documents](#). For information about using shared runbooks, see [Using shared SSM documents](#).

4. Run the automation.

### Note

When running automations across multiple Regions, accounts, or OUs, the automation you run from the primary account starts child automations in each of the target accounts. The automation in the primary account contains `aws:executeAutomation` steps for each of the target accounts.

5. Use the [GetAutomationExecution](#), [DescribeAutomationStepExecutions](#), and [DescribeAutomationExecutions](#) API operations from the AWS Systems Manager console or the AWS CLI to monitor automation progress. The output of the steps for the automation in your primary account will be the `AutomationExecutionId` of the child automations. To view

the output of the child automations created in your target accounts, be sure to specify the appropriate account, Region, and AutomationExecutionId in your request.

## Setting up management account permissions for multi-Region and multi-account automation

Use the following procedure to create the required IAM roles for Systems Manager Automation multi-Region and multi-account automation by using AWS CloudFormation. This procedure describes how to create the **AWS-SystemsManager-AutomationAdministrationRole** role. You only need to create this role in the Automation central account. This procedure also describes how to create the **AWS-SystemsManager-AutomationExecutionRole** role. You must create this role in *every* account that you want to target to run multi-Region and multi-account automations. We recommend using AWS CloudFormation StackSets to create the **AWS-SystemsManager-AutomationExecutionRole** role in the accounts you want to target to run multi-Region and multi-account automations.

### To create the required IAM administration role for multi-Region and multi-account automations by using AWS CloudFormation

1. Download and unzip the [AWS-SystemsManager-AutomationAdministrationRole.zip](#). Or, if your accounts are managed by AWS Organizations [AWS-SystemsManager-AutomationAdministrationRole \(org\).zip](#). This file contains the AWS-SystemsManager-AutomationAdministrationRole.yaml AWS CloudFormation template file.
2. Open the AWS CloudFormation console at <https://console.aws.amazon.com/cloudformation>.
3. Choose **Create stack**.
4. In the **Specify template** section, choose **Upload a template**.
5. Choose **Choose file**, and then choose the AWS-SystemsManager-AutomationAdministrationRole.yaml AWS CloudFormation template file.
6. Choose **Next**.
7. On the **Specify stack details** page, in the **Stack name** field, enter a name.
8. Choose **Next**.
9. On the **Configure stack options** page, enter values for any options you want to use. Choose **Next**.
10. On the **Review** page, scroll down and choose the **I acknowledge that AWS CloudFormation might create IAM resources with custom names** option.

## 11. Choose **Create stack**.

AWS CloudFormation shows the **CREATE\_IN\_PROGRESS** status for approximately three minutes. The status changes to **CREATE\_COMPLETE**.

You must repeat the following procedure in *every* account that you want to target to run multi-Region and multi-account automations.

### **To create the required IAM automation role for multi-Region and multi-account automations by using AWS CloudFormation**

1. Download the [AWS-SystemsManager-AutomationExecutionRole.zip](#). Or, if your accounts are managed by AWS Organizations [AWS-SystemsManager-AutomationExecutionRole \(org\).zip](#). This file contains the `AWS-SystemsManager-AutomationExecutionRole.yaml` AWS CloudFormation template file.
2. Open the AWS CloudFormation console at <https://console.aws.amazon.com/cloudformation>.
3. Choose **Create stack**.
4. In the **Specify template** section, choose **Upload a template**.
5. Choose **Choose file**, and then choose the `AWS-SystemsManager-AutomationExecutionRole.yaml` AWS CloudFormation template file.
6. Choose **Next**.
7. On the **Specify stack details** page, in the **Stack name** field, enter a name.
8. In the **Parameters** section, in the **AdminAccountId** field, enter the ID for the Automation central account.
9. If you are setting up this role for an AWS Organizations environment, there is another field in the section called **OrganizationID**. Enter the ID of your AWS organization.
10. Choose **Next**.
11. On the **Configure stack options** page, enter values for any options you want to use. Choose **Next**.
12. On the **Review** page, scroll down and choose the **I acknowledge that AWS CloudFormation might create IAM resources with custom names** option.
13. Choose **Create stack**.

AWS CloudFormation shows the **CREATE\_IN\_PROGRESS** status for approximately three minutes. The status changes to **CREATE\_COMPLETE**.

## Run an automation in multiple Regions and accounts (console)

The following procedure describes how to use the Systems Manager console to run an automation in multiple Regions and accounts from the Automation management account.

### Before you begin

Before you complete the following procedure, note the following information:

- The user or role you use to run a multi-Region or multi-account automation must have the `iam:PassRole` permission for the `AWS-SystemsManager-AutomationAdministrationRole` role.
- AWS account IDs or OUs where you want to run the automation.
- [Regions supported by Systems Manager](#) where you want to run the automation.
- The tag key and the tag value, or the name of the resource group, where you want to run the automation.

### To run an automation in multiple Regions and accounts

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Automation**, and then choose **Execute automation**.
3. In the **Automation document** list, choose a runbook. Choose one or more options in the **Document categories** pane to filter SSM documents according to their purpose. To view a runbook that you own, choose the **Owned by me** tab. To view a runbook that is shared with your account, choose the **Shared with me** tab. To view all runbooks, choose the **All documents** tab.

#### Note

You can view information about a runbook by choosing the runbook name.

4. In the **Document details** section, verify that **Document version** is set to the version that you want to run. The system includes the following version options:

- **Default version at runtime** – Choose this option if the Automation runbook is updated periodically and a new default version is assigned.
  - **Latest version at runtime** – Choose this option if the Automation runbook is updated periodically, and you want to run the version that was most recently updated.
  - **1 (Default)** – Choose this option to run the first version of the document, which is the default.
5. Choose **Next**.
  6. On the **Execute automation document** page, choose **Multi-account and Region**.
  7. In the **Target accounts and Regions** section, use the **Accounts and organizational (OUs)** field to specify the different AWS accounts or AWS organizational units (OUs) where you want to run the automation. Separate multiple accounts or OUs with a comma.
  8. Use the **AWS Regions** list to choose one or more Regions where you want to run the automation.
  9. Use the **Multi-Region and account rate control** options to restrict the automation to a limited number of accounts running in a limited number of Regions. These options don't restrict the number of AWS resources that can run the automations.
    - a. In the **Location (account-Region pair) concurrency** section, choose an option to restrict the number of automations that can run in multiple accounts and Regions at the same time. For example, if you choose to run an automation in five (5) AWS accounts, which are located in four (4) AWS Regions, then Systems Manager runs automations in a total of 20 account-Region pairs. You can use this option to specify an absolute number, such as **2**, so that the automation only runs in two account-Region pairs at the same time. Or you can specify a percentage of the account-Region pairs that can run at the same time. For example, with 20 account-Region pairs, if you specify 20%, then the automation simultaneously runs in a maximum of five (5) account-Region pairs.
      - Choose **targets** to enter an absolute number of account-Region pairs that can run the automation simultaneously.
      - Choose **percent** to enter a percentage of the total number of account-Region pairs that can run the automation simultaneously.
    - b. In the **Error threshold** section, choose an option:
      - Choose **errors** to enter an absolute number of errors allowed before Automation stops sending the automation to other resources.

- Choose **percent** to enter a percentage of errors allowed before Automation stops sending the automation to other resources.
10. In the **Targets** section, choose how you want to target the AWS resources where you want to run the Automation. These options are required.
    - a. Use the **Parameter** list to choose a parameter. The items in the **Parameter** list are determined by the parameters in the Automation runbook that you selected at the start of this procedure. By choosing a parameter you define the type of resource on which the Automation workflow runs.
    - b. Use the **Targets** list to choose how you want to target resources.
      - i. If you chose to target resources by using parameter values, then enter the parameter value for the parameter you chose in the **Input parameters** section.
      - ii. If you chose to target resources by using AWS Resource Groups, then choose the name of the group from the **Resource Group** list.
      - iii. If you chose to target resources by using tags, then enter the tag key and (optionally) the tag value in the fields provided. Choose **Add**.
      - iv. If you want to run an Automation runbook on all instances in the current AWS account and AWS Region, then choose **All instances**.
  11. In the **Input parameters** section, specify the required inputs. Choose the AWS-SystemsManager-AutomationAdministrationRole IAM service role from the **AutomationAssumeRole** list.

**Note**

You might not need to choose some of the options in the **Input parameters** section. This is because you targeted resources in multiple Regions and accounts by using tags or a resource group. For example, if you chose the AWS-RestartEC2Instance runbook, then you don't need to specify or choose instance IDs in the **Input parameters** section. The automation locates the instances to restart by using the tags you specified.

12. (Optional) Choose a CloudWatch alarm to apply to your automation for monitoring. To attach a CloudWatch alarm to your automation, the IAM principal that starts the automation must have permission for the `iam:createServiceLinkedRole` action. For more information about CloudWatch alarms, see [Using Amazon CloudWatch alarms](#). Note that if your alarm

activates, the automation is cancelled and any `OnCancel` steps you have defined run. If you use AWS CloudTrail, you will see the API call in your trail.

13. Use the options in the **Rate control** section to restrict the number of AWS resources that can run the Automation within each account-Region pair.

In the **Concurrency** section, choose an option:

- Choose **targets** to enter an absolute number of targets that can run the Automation workflow simultaneously.
- Choose **percentage** to enter a percentage of the target set that can run the Automation workflow simultaneously.

14. In the **Error threshold** section, choose an option:

- Choose **errors** to enter an absolute number of errors allowed before Automation stops sending the workflow to other resources.
- Choose **percentage** to enter a percentage of errors allowed before Automation stops sending the workflow to other resources.

15. Choose **Execute**.

## Run an Automation in multiple Regions and accounts (command line)

The following procedure describes how to use the AWS CLI (on Linux or Windows) or AWS Tools for PowerShell to run an automation in multiple Regions and accounts from the Automation management account.

### Before you begin

Before you complete the following procedure, note the following information:

- AWS account IDs or OUs where you want to run the automation.
- [Regions supported by Systems Manager](#) where you want to run the automation.
- The tag key and the tag value, or the name of the resource group, where you want to run the automation.

### To run an automation in multiple Regions and accounts

1. Install and configure the AWS CLI or the AWS Tools for PowerShell, if you haven't already.

For information, see [Installing or updating the latest version of the AWS CLI](#) and [Installing the AWS Tools for PowerShell](#).

2. Use the following format to create a command to run an automation in multiple Regions and accounts. Replace each *example resource placeholder* with your own information.

### Linux & macOS

```
aws ssm start-automation-execution \
  --document-name runbook name \
  --parameters AutomationAssumeRole=arn:aws:iam::management account ID:role/AWS-SystemsManager-AutomationAdministrationRole \
  --target-parameter-name parameter name \
  --targets Key=tag key,Values=value \
  --target-locations Accounts=account ID,account ID 2,Regions=Region,Region 2,ExecutionRoleName=AWS-SystemsManager-AutomationExecutionRole
```

### Windows

```
aws ssm start-automation-execution ^
  --document-name runbook name ^
  --parameters AutomationAssumeRole=arn:aws:iam::management account ID:role/AWS-SystemsManager-AutomationAdministrationRole ^
  --target-parameter-name parameter name ^
  --targets Key=tag key,Values=value ^
  --target-locations Accounts=account ID,account ID 2,Regions=Region,Region 2,ExecutionRoleName=AWS-SystemsManager-AutomationExecutionRole
```

### PowerShell

```
$Targets = New-Object Amazon.SimpleSystemsManagement.Model.Target
$Targets.Key = "tag key"
$Targets.Values = "value"

Start-SSMAutomationExecution `
  -DocumentName "runbook name" `
  -Parameter @{
    "AutomationAssumeRole"="arn:aws:iam::management account ID:role/AWS-SystemsManager-AutomationAdministrationRole" } `
  -TargetParameterName "parameter name" `
```

```
-Target $Targets `
-TargetLocation @{
"Accounts"="account ID","account ID 2";
"Regions"="Region","Region 2";
"ExecutionRoleName"="AWS-SystemsManager-AutomationExecutionRole" }
```

Here are several examples.

**Example 1:** This example restarts EC2 instances in three Regions across an entire AWS Organizations organization. This is achieved by targeting the root ID of the organization, and including child OUs.

### Linux & macOS

```
aws ssm start-automation-execution \
  --document-name "AWS-RestartEC2Instance" \
  --target-parameter-name InstanceId \
  --targets '[{"Key":"AWS::EC2::Instance","Values":["*"]}]' \
  --target-locations '[{
    "Accounts": ["r-example"],
    "IncludeChildOrganizationUnits": true,
    "Regions": ["us-east-1", "us-east-2", "us-west-2"]
  }]'
```

### Windows

```
aws ssm start-automation-execution \
  --document-name "AWS-RestartEC2Instance" ^
  --target-parameter-name InstanceId ^
  --targets '[{"Key":"AWS::EC2::Instance","Values":["*"]}]' ^
  --target-locations '[{
    "Accounts": ["r-example"],
    "IncludeChildOrganizationUnits": true,
    "Regions": ["us-east-1", "us-east-2", "us-west-2"]
  }]'
```

### PowerShell

```
Start-SSMAutomationExecution `
  -DocumentName "AWS-RestartEC2Instance" `
  -TargetParameterName "InstanceId" `
```

```
-Targets ' [{"Key": "AWS::EC2::Instance", "Values": ["*"]} ]'
-TargetLocation @ {
    "Accounts" = "r-example";
    "Regions" = "us-east-1", "us-east-2", "us-west-2";
    "IncludeChildOrganizationUnits" = true
}
```

**Example 2:** This example restarts specific EC2 instances in different accounts and Regions.

## Linux & macOS

```
aws ssm start-automation-execution \
  --document-name "AWS-RestartEC2Instance" \
  --target-parameter-name InstanceId \
  --target-locations '[ {
    "Accounts": ["123456789012"],
    "Targets": [ {
      "Key": "ParameterValues",
      "Values": ["i-02573cafcfEXAMPLE", "i-0471e04240EXAMPLE"]
    } ],
    "TargetLocationMaxConcurrency": "100%",
    "Regions": ["us-east-1"]
  }, {
    "Accounts": ["987654321098"],
    "Targets": [ {
      "Key": "ParameterValues",
      "Values": ["i-07782c72faEXAMPLE"]
    } ],
    "TargetLocationMaxConcurrency": "100%",
    "Regions": ["us-east-2"]
  } ]'
```

## Windows

```
aws ssm start-automation-execution ^
  --document-name "AWS-RestartEC2Instance" ^
  --target-parameter-name InstanceId ^
  --target-locations '[ {
    "Accounts": ["123456789012"],
    "Targets": [ {
      "Key": "ParameterValues",
      "Values": ["i-02573cafcfEXAMPLE", "i-0471e04240EXAMPLE"]
    } ],
```

```

        "TargetLocationMaxConcurrency": "100%",
        "Regions": ["us-east-1"]
    }, {
        "Accounts": ["987654321098"],
        "Targets": [{
            "Key": "ParameterValues",
            "Values": ["i-07782c72faEXAMPLE"]
        }],
        "TargetLocationMaxConcurrency": "100%",
        "Regions": ["us-east-2"]
    }]
}'

```

## PowerShell

```

Start-SSMAutomationExecution `
    -DocumentName "AWS-RestartEC2Instance" `
    -TargetParameterName "InstanceId" `
    -Targets '["Key": "AWS::EC2::Instance", "Values": ["*"]]'
    -TargetLocation @(
        "Accounts"="123456789012",
        "Targets"= @(
            "Key": "ParameterValues",
            "Values": ["i-02573cafcfEXAMPLE", "i-0471e04240EXAMPLE"]
        ),
        "TargetLocationMaxConcurrency"="100%",
        "Regions"=["us-east-1"]
    ), {
        "Accounts"="987654321098",
        "Targets": @(
            "Key": "ParameterValues",
            "Values": ["i-07782c72faEXAMPLE"]
        ),
        "TargetLocationMaxConcurrency": "100%",
        "Regions"=["us-east-2"]
    })

```

**Example 3:** This example restarts EC2 instances in the 123456789012 and 987654321098 accounts, which are located in the us-east-2 and us-west-1 Regions. The instances must be tagged with the tag key-pair value Env-PROD.

## Linux & macOS

```
aws ssm start-automation-execution \
  --document-name AWS-RestartEC2Instance \
  --parameters AutomationAssumeRole=arn:aws:iam::123456789012:role/AWS-
SystemsManager-AutomationAdministrationRole \
  --target-parameter-name InstanceId \
  --targets Key=tag:Env,Values=PROD \
  --target-locations Accounts=123456789012,987654321098,Regions=us-
east-2,us-west-1,ExecutionRoleName=AWS-SystemsManager-AutomationExecutionRole
```

## Windows

```
aws ssm start-automation-execution ^
  --document-name AWS-RestartEC2Instance ^
  --parameters AutomationAssumeRole=arn:aws:iam::123456789012:role/AWS-
SystemsManager-AutomationAdministrationRole ^
  --target-parameter-name InstanceId ^
  --targets Key=tag:Env,Values=PROD ^
  --target-locations Accounts=123456789012,987654321098,Regions=us-
east-2,us-west-1,ExecutionRoleName=AWS-SystemsManager-AutomationExecutionRole
```

## PowerShell

```
$Targets = New-Object Amazon.SimpleSystemsManagement.Model.Target
$Targets.Key = "tag:Env"
$Targets.Values = "PROD"

Start-SSMAutomationExecution `
  -DocumentName "AWS-RestartEC2Instance" `
  -Parameter @{
    "AutomationAssumeRole"="arn:aws:iam::123456789012:role/AWS-
SystemsManager-AutomationAdministrationRole" } `
  -TargetParameterName "InstanceId" `
  -Target $Targets `
  -TargetLocation @{
    "Accounts"="123456789012","987654321098";
    "Regions"="us-east-2","us-west-1";
    "ExecutionRoleName"="AWS-SystemsManager-AutomationExecutionRole" }
```

**Example 4:** This example restarts EC2 instances in the 123456789012 and 987654321098 accounts, which are located in the eu-central-1 Region. The instances must be members of the prod-instances AWS resource group.

## Linux & macOS

```
aws ssm start-automation-execution \
  --document-name AWS-RestartEC2Instance \
  --parameters AutomationAssumeRole=arn:aws:iam::123456789012:role/AWS-
SystemsManager-AutomationAdministrationRole \
  --target-parameter-name InstanceId \
  --targets Key=ResourceGroup,Values=prod-instances \
  --target-locations Accounts=123456789012,987654321098,Regions=eu-
central-1,ExecutionRoleName=AWS-SystemsManager-AutomationExecutionRole
```

## Windows

```
aws ssm start-automation-execution ^
  --document-name AWS-RestartEC2Instance ^
  --parameters AutomationAssumeRole=arn:aws:iam::123456789012:role/AWS-
SystemsManager-AutomationAdministrationRole ^
  --target-parameter-name InstanceId ^
  --targets Key=ResourceGroup,Values=prod-instances ^
  --target-locations Accounts=123456789012,987654321098,Regions=eu-
central-1,ExecutionRoleName=AWS-SystemsManager-AutomationExecutionRole
```

## PowerShell

```
$Targets = New-Object Amazon.SimpleSystemsManagement.Model.Target
$Targets.Key = "ResourceGroup"
$Targets.Values = "prod-instances"

Start-SSMAutomationExecution `
  -DocumentName "AWS-RestartEC2Instance" `
  -Parameter @{
    "AutomationAssumeRole"="arn:aws:iam::123456789012:role/AWS-
SystemsManager-AutomationAdministrationRole" } `
  -TargetParameterName "InstanceId" `
  -Target $Targets `
  -TargetLocation @{
```

```
"Accounts"="123456789012", "987654321098";
"Regions"="eu-central-1";
"ExecutionRoleName"="AWS-SystemsManager-AutomationExecutionRole" }
```

**Example 5:** This example restarts EC2 instances in the ou-1a2b3c-4d5e6c AWS organizational unit (OU). The instances are located in the us-west-1 and us-west-2 Regions. The instances must be members of the WebServices AWS resource group.

## Linux & macOS

```
aws ssm start-automation-execution \
  --document-name AWS-RestartEC2Instance \
  --parameters AutomationAssumeRole=arn:aws:iam::123456789012:role/AWS-
SystemsManager-AutomationAdministrationRole \
  --target-parameter-name InstanceId \
  --targets Key=ResourceGroup,Values=WebServices \
  --target-locations Accounts=ou-1a2b3c-4d5e6c,Regions=us-west-1,us-
west-2,ExecutionRoleName=AWS-SystemsManager-AutomationExecutionRole
```

## Windows

```
aws ssm start-automation-execution ^
  --document-name AWS-RestartEC2Instance ^
  --parameters AutomationAssumeRole=arn:aws:iam::123456789012:role/AWS-
SystemsManager-AutomationAdministrationRole ^
  --target-parameter-name InstanceId ^
  --targets Key=ResourceGroup,Values=WebServices ^
  --target-locations Accounts=ou-1a2b3c-4d5e6c,Regions=us-west-1,us-
west-2,ExecutionRoleName=AWS-SystemsManager-AutomationExecutionRole
```

## PowerShell

```
$Targets = New-Object Amazon.SimpleSystemsManagement.Model.Target
$Targets.Key = "ResourceGroup"
$Targets.Values = "WebServices"

Start-SSMAutomationExecution `
  -DocumentName "AWS-RestartEC2Instance" `
  -Parameter @{
    "AutomationAssumeRole"="arn:aws:iam::123456789012:role/AWS-
SystemsManager-AutomationAdministrationRole" } `
```

```
-TargetParameterName "InstanceId" `
-Target $Targets `
-TargetLocation @{
  "Accounts"="ou-1a2b3c-4d5e6c";
  "Regions"="us-west-1";
  "ExecutionRoleName"="AWS-SystemsManager-AutomationExecutionRole" }
```

The system returns information similar to the following.

#### Linux & macOS

```
{
  "AutomationExecutionId": "4f7ca192-7e9a-40fe-9192-5cb15EXAMPLE"
}
```

#### Windows

```
{
  "AutomationExecutionId": "4f7ca192-7e9a-40fe-9192-5cb15EXAMPLE"
}
```

#### PowerShell

```
4f7ca192-7e9a-40fe-9192-5cb15EXAMPLE
```

3. Run the following command to view details for the automation. Replace *automation execution ID* with your own information.

#### Linux & macOS

```
aws ssm describe-automation-executions \
  --filters Key=ExecutionId,Values=automation execution ID
```

#### Windows

```
aws ssm describe-automation-executions ^
  --filters Key=ExecutionId,Values=automation execution ID
```

## PowerShell

```
Get-SSMAutomationExecutionList | `
    Where {$_.AutomationExecutionId -eq "automation execution ID"}
```

4. Run the following command to view details about the automation progress.

## Linux & macOS

```
aws ssm get-automation-execution \
    --automation-execution-id 4f7ca192-7e9a-40fe-9192-5cb15EXAMPLE
```

## Windows

```
aws ssm get-automation-execution ^
    --automation-execution-id 4f7ca192-7e9a-40fe-9192-5cb15EXAMPLE
```

## PowerShell

```
Get-SSMAutomationExecution `
    -AutomationExecutionId a4a3c0e9-7efd-462a-8594-01234EXAMPLE
```

### Note

You can also monitor the status of the automation in the console. In the **Automation executions** list, choose the automation you just ran and then choose the **Execution steps** tab. This tab shows the status of the automation actions.

## More info

[Centralized multi-account and multi-Region patching with AWS Systems Manager Automation](#)

## Run automations based on EventBridge events

You can start an automation by specifying a runbook as the target of an Amazon EventBridge event. You can start automations according to a schedule, or when a specific AWS system event

occurs. For example, let's say you create a runbook named *BootStrapInstances* that installs software on an instance when an instance starts. To specify the *BootStrapInstances* runbook (and corresponding automation) as a target of an EventBridge event, you first create a new EventBridge rule. (Here's an example rule: **Service name:** EC2, **Event Type:** EC2 Instance State-change Notification, **Specific state(s):** running, **Any instance.**) Then you use the following procedures to specify the *BootStrapInstances* runbook as the target of the event using the EventBridge console and AWS Command Line Interface (AWS CLI). When a new instance starts, the system runs the automation and installs software.

For information about creating runbooks, see [Creating your own runbooks](#).

### Creating an EventBridge event that uses a runbook (console)

Use the following procedure to configure a runbook as the target of a EventBridge event.

#### To configure a runbook as a target of a EventBridge event rule

1. Open the Amazon EventBridge console at <https://console.aws.amazon.com/events/>.
2. In the navigation pane, choose **Rules**.
3. Choose **Create rule**.
4. Enter a name and description for the rule.

A rule can't have the same name as another rule in the same Region and on the same event bus.

5. For **Event bus**, choose the event bus that you want to associate with this rule. If you want this rule to respond to matching events that come from your own AWS account, select **default**. When an AWS service in your account emits an event, it always goes to your account's default event bus.
6. Choose how the rule is triggered.

| To create a rule based on... | Do this...   |
|------------------------------|--|
| Event                        | <ol style="list-style-type: none"> <li>a. For <b>Rule type</b>, choose <b>Rule with an event pattern</b>.</li> <li>b. Choose <b>Next</b>.</li> </ol> |

| To create a rule based on... | Do this...  |  |
|------------------------------|---|--|
|                              | <p>c. For <b>Event source</b>, choose <b>AWS events or EventBridge partner events</b>.</p> <p>d. In the <b>Event pattern</b> section, do one of the following:</p> <ul style="list-style-type: none"><li>• To use a template to create your event pattern, choose <b>Event pattern form</b> and choose <b>Event source</b>, <b>AWS service</b>, and <b>Event type</b>. If you choose <b>All Events</b> as the event type, all events emitted by the AWS service will match the rule.</li></ul> <p>To customize the template, choose <b>Custom pattern (JSON editor)</b> and make your changes.</p> <ul style="list-style-type: none"><li>• To use a custom event pattern, choose <b>Custom pattern (JSON editor)</b> and create your event pattern.</li></ul> |  |

| To create a rule based on... | Do this...   |  |
|------------------------------|--|--|
| Schedule                     | <ol style="list-style-type: none"> <li>a. For <b>Rule type</b>, choose <b>Schedule</b>.</li> <li>b. Choose <b>Next</b>.</li> <li>c. For <b>Schedule pattern</b>, do one of the following: <ul style="list-style-type: none"> <li>• To use a cron expression to define the schedule, choose <b>A fine-grained schedule that runs at a specific time, such as 8:00 a.m. PST on the first Monday of every month</b> and enter the cron expression.</li> <li>• To use a rate expression to define the schedule, choose <b>A schedule that runs at a regular rate, such as every 10 minutes</b> and enter the rate expression.</li> </ul> </li> </ol> |  |

7. Choose **Next**.
8. For **Target types**, choose **AWS service**.
9. For **Select a target**, choose **Systems Manager Automation**.
10. For **Document**, choose a runbook to use when your target is invoked.
11. In the **Configure automation parameter(s)** section, either keep the default parameter values (if available) or enter your own values.

**Note**

To create a target, you must specify a value for each required parameter. If you don't, the system creates the rule, but the rule won't run.

12. For many target types, EventBridge needs permissions to send events to the target. In these cases, EventBridge can create the IAM role needed for your rule to run. Do one of the following:
  - To create an IAM role automatically, choose **Create a new role for this specific resource**.
  - To use an IAM role that you created earlier, choose **Use existing role** and select the existing role from the dropdown. Note that you might need to update the trust policy for your IAM role to include EventBridge. The following is an example:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "",
      "Effect": "Allow",
      "Principal": {
        "Service": [
          "events.amazonaws.com",
          "ssm.amazonaws.com"
        ]
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

13. Choose **Next**.
14. (Optional) Enter one or more tags for the rule. For more information, see [Tagging Your Amazon EventBridge Resources](#) in the *Amazon EventBridge User Guide*.
15. Choose **Next**.
16. Review the details of the rule and choose **Create rule**.

## Create an EventBridge event that uses a runbook (command line)

The following procedure describes how to use the AWS CLI (on Linux or Windows) or AWS Tools for PowerShell to create an EventBridge event rule and configure a runbook as the target.

### To configure a runbook as a target of an EventBridge event rule

1. Install and configure the AWS CLI or the AWS Tools for PowerShell, if you haven't already.

For information, see [Installing or updating the latest version of the AWS CLI](#) and [Installing the AWS Tools for PowerShell](#).

2. Create a command to specify a new EventBridge event rule. Replace each *example resource placeholder* with your own information.

*Triggers based on a schedule*

#### Linux & macOS

```
aws events put-rule \  
--name "rule name" \  
--schedule-expression "cron or rate expression"
```

#### Windows

```
aws events put-rule ^  
--name "rule name" ^  
--schedule-expression "cron or rate expression"
```

#### PowerShell

```
Write-CWRule `\  
-Name "rule name" `\  
-ScheduleExpression "cron or rate expression"
```

The following example creates an EventBridge event rule that starts every day at 9:00 AM (UTC).

#### Linux & macOS

```
aws events put-rule \  

```

```
--name "DailyAutomationRule" \  
--schedule-expression "cron(0 9 * * ? *)"
```

## Windows

```
aws events put-rule ^  
--name "DailyAutomationRule" ^  
--schedule-expression "cron(0 9 * * ? *)"
```

## PowerShell

```
Write-CWERule `\  
-Name "DailyAutomationRule" `\  
-ScheduleExpression "cron(0 9 * * ? *)"
```

## Triggers based on an event

### Linux & macOS

```
aws events put-rule \  
--name "rule name" \  
--event-pattern "{\"source\":[\"aws.service\"],\"detail-type\":[\"service event detail type\"]}"
```

### Windows

```
aws events put-rule ^  
--name "rule name" ^  
--event-pattern "{\"source\":[\"aws.service\"],\"detail-type\":[\"service event detail type\"]}"
```

### PowerShell

```
Write-CWERule `\  
-Name "rule name" `\  
-EventPattern '{"source":["aws.service"],"detail-type":["service event detail type"]}'
```

The following example creates an EventBridge event rule that starts when any EC2 instance in the Region changes state.

### Linux & macOS

```
aws events put-rule \  
--name "EC2InstanceStateChanges" \  
--event-pattern "{\"source\":[\"aws.ec2\"],\"detail-type\":[\"EC2 Instance  
State-change Notification\"]}"
```

### Windows

```
aws events put-rule ^  
--name "EC2InstanceStateChanges" ^  
--event-pattern "{\"source\":[\"aws.ec2\"],\"detail-type\":[\"EC2 Instance  
State-change Notification\"]}"
```

### PowerShell

```
Write-CWRule `   
-Name "EC2InstanceStateChanges" `   
-EventPattern '{"source":["aws.ec2"],"detail-type":["EC2 Instance State-change  
Notification"]}'
```

The command returns details for the new EventBridge rule similar to the following.

### Linux & macOS

```
{  
  "RuleArn": "arn:aws:events:us-east-1:123456789012:rule/automationrule"  
}
```

### Windows

```
{  
  "RuleArn": "arn:aws:events:us-east-1:123456789012:rule/automationrule"  
}
```

## PowerShell

```
arn:aws:events:us-east-1:123456789012:rule/EC2InstanceStateChanges
```

3. Create a command to specify a runbook as a target of the EventBridge event rule you created in step 2. Replace each *example resource placeholder* with your own information.

## Linux & macOS

```
aws events put-targets \
--rule rule name \
--targets '{"Arn": "arn:aws:ssm:region:account ID:automation-definition/runbook name", "Input": "{\\"input parameter\\": [\\"value\\"], \\"AutomationAssumeRole\\": [\\"arn:aws:iam::123456789012:role/AutomationServiceRole\\"]}", "Id": "target ID", "RoleArn": "arn:aws:iam::123456789012:role/service-role/EventBridge service role"}'
```

## Windows

```
aws events put-targets ^
--rule rule name ^
--targets '{"Arn": "arn:aws:ssm:region:account ID:automation-definition/runbook name", "Input": "{\\"input parameter\\": [\\"value\\"], \\"AutomationAssumeRole\\": [\\"arn:aws:iam::123456789012:role/AutomationServiceRole\\"]}", "Id": "target ID", "RoleArn": "arn:aws:iam::123456789012:role/service-role/EventBridge service role"}'
```

## PowerShell

```
$Target = New-Object Amazon.CloudWatchEvents.Model.Target
$Target.Id = "target ID"
$Target.Arn = "arn:aws:ssm:region:account ID:automation-definition/runbook name"
$Target.RoleArn = "arn:aws:iam::123456789012:role/service-role/EventBridge service role"
$Target.Input = '{"input parameter":["value"],"AutomationAssumeRole": [\'arn:aws:iam::123456789012:role/AutomationServiceRole\']}'

Write-CWETarget `
-Rule "rule name" `
-Target $Target
```

The following example creates an EventBridge event target that starts the specified instance ID using the runbook `AWS-StartEC2Instance`.

## Linux & macOS

```
aws events put-targets \
--rule DailyAutomationRule \
--targets '{"Arn": "arn:aws:ssm:region*:automation-definition/AWS-StartEC2Instance", "Input": "{\\"InstanceId\\": [\\"i-02573cafcfEXAMPLE\\"], \\"AutomationAssumeRole\\": [\\"arn:aws:iam::123456789012:role/AutomationServiceRole\\"]}", "Id": "Target1", "RoleArn": "arn:aws:iam::123456789012:role/service-role/AWS_Events_Invoke_Start_Automation_Execution_1213609520"}'
```

## Windows

```
aws events put-targets ^
--rule DailyAutomationRule ^
--targets '{"Arn": "arn:aws:ssm:region*:automation-definition/AWS-StartEC2Instance", "Input": "{\\"InstanceId\\": [\\"i-02573cafcfEXAMPLE\\"], \\"AutomationAssumeRole\\": [\\"arn:aws:iam::123456789012:role/AutomationServiceRole\\"]}", "Id": "Target1", "RoleArn": "arn:aws:iam::123456789012:role/service-role/AWS_Events_Invoke_Start_Automation_Execution_1213609520"}'
```

## PowerShell

```
$Target = New-Object Amazon.CloudWatchEvents.Model.Target
$Target.Id = "Target1"
$Target.Arn = "arn:aws:ssm:region*:automation-definition/AWS-StartEC2Instance"
$Target.RoleArn = "arn:aws:iam::123456789012:role/service-role/AWS_Events_Invoke_Start_Automation_Execution_1213609520"
$Target.Input = '{"InstanceId":["i-02573cafcfEXAMPLE"],"AutomationAssumeRole":["arn:aws:iam::123456789012:role/AutomationServiceRole"]}'

Write-CWETarget `
-Rule "DailyAutomationRule" `
-Target $Target
```

The system returns information like the following.

## Linux & macOS

```
{
  "FailedEntries": [],
  "FailedEntryCount": 0
}
```

## Windows

```
{
  "FailedEntries": [],
  "FailedEntryCount": 0
}
```

## PowerShell

There is no output if the command succeeds for PowerShell.

## Run an automation step by step

The following procedures describe how to use the AWS Systems Manager console and AWS Command Line Interface (AWS CLI) to run an automation using the manual execution mode. By using the manual execution mode, the automation starts in a *Waiting* status and pauses in the *Waiting* status between each step. This allows you to control when the automation proceeds, which is useful if you need to review the result of a step before continuing.

The automation runs in the context of the current user. This means that you don't need to configure additional IAM permissions as long as you have permission to use the runbook, and any actions called by the runbook. If you have administrator permissions in IAM, then you already have permission to run this automation.

### Running an automation step by step (console)

The following procedure shows how to use the Systems Manager console to manually run an automation step by step.

## To run an automation step by step

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Automation**, and then choose **Execute automation**.
3. In the **Automation document** list, choose a runbook. Choose one or more options in the **Document categories** pane to filter SSM documents according to their purpose. To view a runbook that you own, choose the **Owned by me** tab. To view a runbook that is shared with your account, choose the **Shared with me** tab. To view all runbooks, choose the **All documents** tab.

### Note

You can view information about a runbook by choosing the runbook name.

4. In the **Document details** section, verify that **Document version** is set to the version that you want to run. The system includes the following version options:
  - **Default version at runtime** – Choose this option if the Automation runbook is updated periodically and a new default version is assigned.
  - **Latest version at runtime** – Choose this option if the Automation runbook is updated periodically, and you want to run the version that was most recently updated.
  - **1 (Default)** – Choose this option to run the first version of the document, which is the default.
5. Choose **Next**.
6. In the **Execution Mode** section, choose **Manual execution**.
7. In the **Input parameters** section, specify the required inputs. Optionally, you can choose an IAM service role from the **AutomationAssumeRole** list.
8. Choose **Execute**.
9. Choose **Execute this step** when you're ready to start the first step of the automation. The automation proceeds with step one and pauses before running any subsequent steps specified in the runbook you chose in step 3 of this procedure. If the runbook has multiple steps, you must select **Execute this step** for each step for the automation to proceed. Each time you choose **Execute this step** the action runs.

**Note**

The console displays the status of the automation. If the automation fails to run a step, see [Troubleshooting Systems Manager Automation](#).

10. After you complete all steps specified in the runbook, choose **Complete and view results** to finish the automation and view the results.

## Running an automation step by step (command line)

The following procedure describes how to use the AWS CLI (on Linux, macOS, or Windows) or AWS Tools for PowerShell to manually run an automation step by step.

### To run an automation step by step

1. Install and configure the AWS CLI or the AWS Tools for PowerShell, if you haven't already.

For information, see [Installing or updating the latest version of the AWS CLI](#) and [Installing the AWS Tools for PowerShell](#).

2. Run the following command to start a manual automation. Replace each *example resource placeholder* with your own information.

#### Linux & macOS

```
aws ssm start-automation-execution \  
  --document-name runbook name \  
  --mode Interactive \  
  --parameters runbook parameters
```

#### Windows

```
aws ssm start-automation-execution ^  
  --document-name runbook name ^  
  --mode Interactive ^  
  --parameters runbook parameters
```

#### PowerShell

```
Start-SSMAutomationExecution `
```

```
-DocumentName runbook name \  
-Mode Interactive \  
-Parameter runbook parameters
```

Here is an example using the runbook `AWS-RestartEC2Instance` to restart the specified EC2 instance.

## Linux & macOS

```
aws ssm start-automation-execution \  
  --document-name "AWS-RestartEC2Instance" \  
  --mode Interactive \  
  --parameters "InstanceId=i-02573cafcfEXAMPLE"
```

## Windows

```
aws ssm start-automation-execution ^  
  --document-name "AWS-RestartEC2Instance" ^  
  --mode Interactive ^  
  --parameters "InstanceId=i-02573cafcfEXAMPLE"
```

## PowerShell

```
Start-SSMAutomationExecution \  
  -DocumentName AWS-RestartEC2Instance \  
  -Mode Interactive \  
  -Parameter @{"InstanceId"="i-02573cafcfEXAMPLE"}
```

The system returns information like the following.

## Linux & macOS

```
{  
  "AutomationExecutionId": "ba9cd881-1b36-4d31-a698-0123456789ab"  
}
```

## Windows

```
{
```

```
"AutomationExecutionId": "ba9cd881-1b36-4d31-a698-0123456789ab"
}
```

## PowerShell

```
ba9cd881-1b36-4d31-a698-0123456789ab
```

3. Run the following command when you're ready to start the first step of the automation. Replace each *example resource placeholder* with your own information. The automation proceeds with step one and pauses before running any subsequent steps specified in the runbook you chose in step 1 of this procedure. If the runbook has multiple steps, you must run the following command for each step for the automation to proceed.

## Linux & macOS

```
aws ssm send-automation-signal \
  --automation-execution-id ba9cd881-1b36-4d31-a698-0123456789ab \
  --signal-type StartStep \
  --payload StepName="stopInstances"
```

## Windows

```
aws ssm send-automation-signal ^
  --automation-execution-id ba9cd881-1b36-4d31-a698-0123456789ab ^
  --signal-type StartStep ^
  --payload StepName="stopInstances"
```

## PowerShell

```
Send-SSMAutomationSignal `
  -AutomationExecutionId ba9cd881-1b36-4d31-a698-0123456789ab `
  -SignalType StartStep
  -Payload @{"StepName"="stopInstances"}
```

There is no output if the command succeeds.

4. Run the following command to retrieve the status of each step execution in the automation.

## Linux & macOS

```
aws ssm describe-automation-step-executions \  
  --automation-execution-id ba9cd881-1b36-4d31-a698-0123456789ab
```

## Windows

```
aws ssm describe-automation-step-executions ^  
  --automation-execution-id ba9cd881-1b36-4d31-a698-0123456789ab
```

## PowerShell

```
Get-SSMAutomationStepExecution `\  
  -AutomationExecutionId ba9cd881-1b36-4d31-a698-0123456789ab
```

The system returns information like the following.

## Linux & macOS

```
{  
  "StepExecutions": [  
    {  
      "StepName": "stopInstances",  
      "Action": "aws:changeInstanceState",

      "InstanceStates": [
        "running"
      ]
    },
    "StepExecutionId": "8a4a1e0d-dc3e-4039-a599-0123456789ab",
    "OverriddenParameters": {}
  }
]
}

```

## Windows

```

{
  "StepExecutions": [
    {
      "StepName": "stopInstances",
      "Action": "aws:changeInstanceState",
      "ExecutionStartTime": 1557167178.42,
      "ExecutionEndTime": 1557167220.617,
      "StepStatus": "Success",
      "Inputs": {
        "DesiredState": "\"stopped\"",
        "InstanceIds": "[\"i-02573cafcfEXAMPLE\"]"
      },
      "Outputs": {
        "InstanceStates": [
          "stopped"
        ]
      },
      "StepExecutionId": "654243ba-71e3-4771-b04f-0123456789ab",
    }
  ]
}

```

```

        "OverriddenParameters": {},
        "ValidNextSteps": [
            "startInstances"
        ]
    },
    {
        "StepName": "startInstances",
        "Action": "aws:changeInstanceState",
        "ExecutionStartTime": 1557167273.754,
        "ExecutionEndTime": 1557167480.73,
        "StepStatus": "Success",
        "Inputs": {
            "DesiredState": "\"running\"",
            "InstanceIds": "[\"i-02573cafcfEXAMPLE\"]"
        },
        "Outputs": {
            "InstanceStates": [
                "running"
            ]
        },
        "StepExecutionId": "8a4a1e0d-dc3e-4039-a599-0123456789ab",
        "OverriddenParameters": {}
    }
]
}

```

## PowerShell

```

Action: aws:changeInstanceState
ExecutionEndTime      : 5/6/2019 19:45:46
ExecutionStartTime    : 5/6/2019 19:45:03
FailureDetails        :
FailureMessage        :
Inputs                : {[DesiredState, "stopped"], [InstanceIds,
["i-02573cafcfEXAMPLE"]]}
IsCritical            : False
IsEnd                 : False
MaxAttempts           : 0
NextStep              :
OnFailure             :
Outputs               : {[InstanceStates,
Amazon.Runtime.Internal.Util.AlwaysSendList`1[System.String]]}
OverriddenParameters : {}

```

```

Response           :
ResponseCode       :
StepExecutionId    : 8fcc9641-24b7-40b3-a9be-0123456789ab
StepName           : stopInstances
StepStatus         : Success
TimeoutSeconds     : 0
ValidNextSteps     : {startInstances}

```

5. Run the following command to complete the automation after all steps specified within the chosen runbook have finished. Replace each *example resource placeholder* with your own information.

### Linux & macOS

```

aws ssm stop-automation-execution \
  --automation-execution-id ba9cd881-1b36-4d31-a698-0123456789ab \
  --type Complete

```

### Windows

```

aws ssm stop-automation-execution ^
  --automation-execution-id ba9cd881-1b36-4d31-a698-0123456789ab ^
  --type Complete

```

### PowerShell

```

Stop-SSMAutomationExecution `
  -AutomationExecutionId ba9cd881-1b36-4d31-a698-0123456789ab `
  -Type Complete

```

There is no output if the command succeeds.

## Scheduling automations with State Manager associations

You can start an automation by creating a State Manager association with a runbook. State Manager is a capability of AWS Systems Manager. By creating a State Manager association with a runbook, you can target different types of AWS resources. For example, you can create associations that enforce a desired state on an AWS resource, including the following:

- Attach a Systems Manager role to Amazon Elastic Compute Cloud (Amazon EC2) instances to make them *managed instances*.
- Enforce desired ingress and egress rules for a security group.
- Create or delete Amazon DynamoDB backups.
- Create or delete Amazon Elastic Block Store (Amazon EBS) snapshots.
- Turn off read and write permissions on Amazon Simple Storage Service (Amazon S3) buckets.
- Start, restart, or stop managed instances and Amazon Relational Database Service (Amazon RDS) instances.
- Apply patches to Linux, macOS, and Windows AMIs.

Use the following procedures to create a State Manager association that runs an automation using the AWS Systems Manager console and AWS Command Line Interface (AWS CLI). For general information about associations and information about creating an association that uses an SSM Command document or Policy document, see [Creating associations](#).

## Before you begin

Be aware of the following important details before you run an automation by using State Manager:

- Before you can create an association that uses a runbook, verify that you configured permissions for Automation, a capability of AWS Systems Manager. For more information, see [Setting up Automation](#).
- State Manager associations that use runbooks contribute to the maximum number of concurrently running automations in your AWS account. You can have a maximum of 100 concurrent automations running. For information, see [Systems Manager service quotas](#) in the *Amazon Web Services General Reference*.
- When running an automation, State Manager does not log the API operations initiated by the automation in AWS CloudTrail.
- Systems Manager automatically creates a service-linked role so that State Manager has permission to call Systems Manager Automation API operations. If you want, you can create the service-linked role yourself by running the following command from the AWS CLI or AWS Tools for PowerShell.

Linux & macOS

```
aws iam create-service-linked-role \
```

```
--aws-service-name ssm.amazonaws.com
```

## Windows

```
aws iam create-service-linked-role ^  
--aws-service-name ssm.amazonaws.com
```

## PowerShell

```
New-IAMServiceLinkedRole `   
-AWSServiceName ssm.amazonaws.com
```

For more information about service-linked roles, see [Using service-linked roles for Systems Manager](#).

## Creating an association that runs an automation (console)

The following procedure describes how to use the Systems Manager console to create a State Manager association that runs an automation.

### To create a State Manager association that runs an automation

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **State Manager**, and then choose **Create association**.
3. In the **Name** field, specify a name. This is optional, but recommended.
4. In the **Document** list, choose a runbook. Use the Search bar to filter on **Document type : Equal : Automation** runbooks. To view more runbooks, use the numbers to the right of the Search bar.

#### Note

You can view information about a runbook by choosing the runbook name.

5. Choose **Simple execution** to run the automation on one or more targets by specifying the resource ID for those targets. Choose **Rate control** to run the automation across a fleet of AWS resources by specifying a targeting option such as tags or AWS Resource Groups. You can also

control the operation of the automation across your resources by specifying concurrency and error thresholds.

If you chose **Rate control**, the **Targets** section is displayed.

6. In the **Targets** section, choose a method for targeting resources.

- a. (Required) In the **Parameter** list, choose a parameter. The items in the **Parameter** list are determined by the parameters in the runbook that you selected at the start of this procedure. By choosing a parameter, you define the type of resource on which the automation runs.
- b. (Required) In the **Targets** list, choose a method for targeting the resources.
  - **Resource Group**: Choose the name of the group from the **Resource Group** list. For more information about targeting AWS Resource Groups in runbooks, see [Targeting AWS Resource Groups](#).
  - **Tags**: Enter the tag key and (optionally) the tag value in the fields provided. Choose **Add**. For more information about targeting tags in runbooks, see [Targeting a tag](#).
  - **Parameter Values**: Enter values in the **Input parameters** section. If you specify multiple values, Systems Manager runs a child automation on each value specified.

For example, say that your runbook includes an **InstanceID** parameter. If you target the values of the **InstanceID** parameter when you run the automation, then Systems Manager runs a child automation for each instance ID value specified. The parent automation is complete when the automation finishes running each specified instance, or if the automation fails. You can target a maximum of 50 parameter values. For more information about targeting parameter values in runbooks, see [Targeting parameter values](#).

7. In the **Input parameters** section, specify the required input parameters.

If you chose to target resources by using tags or a resource group, then you might not need to choose some of the options in the **Input parameters** section. For example, if you chose the `AWS-RestartEC2Instance` runbook, and you chose to target instances by using tags, then you don't need to specify or choose instance IDs in the **Input parameters** section. The automation locates the instances to restart by using the tags you specified.

**⚠ Important**

You must specify a role ARN in the **AutomationAssumeRole** field. State Manager uses the assume role to call AWS services specified in the runbook and run Automation associations on your behalf.

8. In the **Specify schedule** section, choose **On Schedule** if you want to run the association at regular intervals. If you choose this option, then use the options provided to create the schedule using Cron or Rate expressions. For more information about Cron and Rate expressions for State Manager, see [Cron and rate expressions for associations](#).

**ℹ Note**

Rate expressions are the preferred scheduling mechanism for State Manager associations that use runbooks. Rate expressions allow more flexibility for running associations in the event that you reach the maximum number of concurrently running automations. With a rate schedule, Systems Manager can retry the automation shortly after receiving notification that concurrent automations have reached their maximum and have been throttled.

Choose **No schedule** if you want to run the association one time.

9. (Optional) In the **Rate Control** section, choose **Concurrency** and **Error threshold** options to control the automation deployment across your AWS resources.
  - a. In the **Concurrency** section, choose an option:
    - Choose **targets** to enter an absolute number of targets that can run the automation simultaneously.
    - Choose **percentage** to enter a percentage of the target set that can run the automation simultaneously.
  - b. In the **Error threshold** section, choose an option:
    - Choose **errors** to enter an absolute number of errors allowed before Automation stops sending the automation to other resources.

- Choose **percentage** to enter a percentage of errors allowed before Automation stops sending the automation to other resources.

For more information about using targets and rate controls with Automation, see [Run automated operations at scale](#).

## 10. Choose **Create Association**.

### **Important**

When you create an association, the association immediately runs against the specified targets. The association then runs based on the cron or rate expression you chose. If you chose **No schedule**, the association doesn't run again.

## Creating an association that runs an automation (command line)

The following procedure describes how to use the AWS CLI (on Linux or Windows) or AWS Tools for PowerShell to create a State Manager association that runs an automation.

### Before you begin

Before you complete the following procedure, make sure you have created an IAM service role that contains the permissions necessary to run the runbook, and configured a trust relationship for Automation, a capability of AWS Systems Manager. For more information, see [Task 1: Create a service role for Automation](#).

### To create an association that runs an automation

1. Install and configure the AWS CLI or the AWS Tools for PowerShell, if you haven't already.

For information, see [Installing or updating the latest version of the AWS CLI](#) and [Installing the AWS Tools for PowerShell](#).

2. Run the following command to view a list of documents.

Linux & macOS

```
aws ssm list-documents
```

## Windows

```
aws ssm list-documents
```

## PowerShell

```
Get-SSMDocumentList
```

Note the name of the runbook that you want to use for the association.

3. Run the following command to view details about the runbook. In the following command, replace *runbook name* with your own information.

## Linux & macOS

```
aws ssm describe-document \  
--name runbook name
```

Note a parameter name (for example, InstanceId) that you want to use for the `--automation-target-parameter-name` option. This parameter determines the type of resource on which the automation runs.

## Windows

```
aws ssm describe-document ^  
--name runbook name
```

Note a parameter name (for example, InstanceId) that you want to use for the `--automation-target-parameter-name` option. This parameter determines the type of resource on which the automation runs.

## PowerShell

```
Get-SSMDocumentDescription \  
-Name runbook name
```

Note a parameter name (for example, InstanceId) that you want to use for the `AutomationTargetParameterName` option. This parameter determines the type of resource on which the automation runs.

4. Create a command that runs an automation using a State Manager association. Replace each *example resource placeholder* with your own information.

### Targeting using tags

#### Linux & macOS

```
aws ssm create-association \  
--association-name association name \  
--targets Key=tag:key name,Values=value \  
--name runbook name \  
--parameters AutomationAssumeRole=arn:aws:iam::123456789012:role/RunbookAssumeRole \  
--automation-target-parameter-name target parameter \  
--schedule "cron or rate expression"
```

#### Note

If you create an association by using the AWS CLI, use the `--targets` parameter to target instances for the association. Don't use the `--instance-id` parameter. The `--instance-id` parameter is a legacy parameter.

#### Windows

```
aws ssm create-association ^  
--association-name association name ^  
--targets Key=tag:key name,Values=value ^  
--name runbook name ^  
--parameters AutomationAssumeRole=arn:aws:iam::123456789012:role/RunbookAssumeRole ^  
--automation-target-parameter-name target parameter ^  
--schedule "cron or rate expression"
```

#### Note

If you create an association by using the AWS CLI, use the `--targets` parameter to target instances for the association. Don't use the `--instance-id` parameter. The `--instance-id` parameter is a legacy parameter.

## PowerShell

```
$Targets = New-Object Amazon.SimpleSystemsManagement.Model.Target
$Targets.Key = "tag:key name"
$Targets.Values = "value"

New-SSMAssociation `
-AssociationName "association name" `
-Target $Targets `
-Name "runbook name" `
-Parameters @{
"AutomationAssumeRole"="arn:aws:iam::123456789012:role/RunbookAssumeRole" } `
-AutomationTargetParameterName "target parameter" `
-ScheduleExpression "cron or rate expression"
```

### Note

If you create an association by using the AWS Tools for PowerShell, use the Target parameter to target instances for the association. Don't use the InstanceId parameter. The InstanceId parameter is a legacy parameter.

## Targeting using parameter values

### Linux & macOS

```
aws ssm create-association \
--association-name association name \
--targets Key=ParameterValues,Values=value,value 2,value 3 \
--name runbook name \
--parameters AutomationAssumeRole=arn:aws:iam::123456789012:role/RunbookAssumeRole \
--automation-target-parameter-name target parameter \
--schedule "cron or rate expression"
```

### Windows

```
aws ssm create-association ^
--association-name association name ^
```

```
--targets Key=ParameterValues,Values=value,value 2,value 3 ^
--name runbook name ^
--parameters AutomationAssumeRole=arn:aws:iam::123456789012:role/
RunbookAssumeRole ^
--automation-target-parameter-name target parameter ^
--schedule "cron or rate expression"
```

## PowerShell

```
$Targets = New-Object Amazon.SimpleSystemsManagement.Model.Target
$Targets.Key = "ParameterValues"
$Targets.Values = "value","value 2","value 3"

New-SSMAssociation `
-AssociationName "association name" `
-Target $Targets `
-Name "runbook name" `
-Parameters @{
"AutomationAssumeRole"="arn:aws:iam::123456789012:role/RunbookAssumeRole"} `
-AutomationTargetParameterName "target parameter" `
-ScheduleExpression "cron or rate expression"
```

## Targeting using AWS Resource Groups

### Linux & macOS

```
aws ssm create-association \
--association-name association name \
--targets Key=ResourceGroup,Values=resource group name \
--name runbook name \
--parameters AutomationAssumeRole=arn:aws:iam::123456789012:role/
RunbookAssumeRole \
--automation-target-parameter-name target parameter \
--schedule "cron or rate expression"
```

### Windows

```
aws ssm create-association ^
--association-name association name ^
--targets Key=ResourceGroup,Values=resource group name ^
--name runbook name ^
```

```
--parameters AutomationAssumeRole=arn:aws:iam::123456789012:role/RunbookAssumeRole ^
--automation-target-parameter-name target parameter ^
--schedule "cron or rate expression"
```

## PowerShell

```
$Targets = New-Object Amazon.SimpleSystemsManagement.Model.Target
$Targets.Key = "ResourceGroup"
$Targets.Values = "resource group name"

New-SSMAssociation `
-AssociationName "association name" `
-Target $Targets `
-Name "runbook name" `
-Parameters @{
"AutomationAssumeRole"="arn:aws:iam::123456789012:role/RunbookAssumeRole"} `
-AutomationTargetParameterName "target parameter" `
-ScheduleExpression "cron or rate expression"
```

## Targeting multiple accounts and Regions

### Linux & macOS

```
aws ssm create-association \
--association-name association name \
--targets Key=ResourceGroup,Values=resource group name \
--name runbook name \
--parameters AutomationAssumeRole=arn:aws:iam::123456789012:role/RunbookAssumeRole \
--automation-target-parameter-name target parameter \
--schedule "cron or rate expression" \
--target-locations
Accounts=111122223333,444455556666,444455556666,Regions=region,region
```

### Windows

```
aws ssm create-association ^
--association-name association name ^
--targets Key=ResourceGroup,Values=resource group name ^
--name runbook name ^
```

```
--parameters AutomationAssumeRole=arn:aws:iam::123456789012:role/RunbookAssumeRole ^
--automation-target-parameter-name target parameter ^
--schedule "cron or rate expression" ^
--target-locations
Accounts=111122223333,444455556666,444455556666,Regions=region,region
```

## PowerShell

```
$Targets = New-Object Amazon.SimpleSystemsManagement.Model.Target
$Targets.Key = "ResourceGroup"
$Targets.Values = "resource group name"

New-SSMAssociation `
-AssociationName "association name" `
-Target $Targets `
-Name "runbook name" `
-Parameters @{
"AutomationAssumeRole"="arn:aws:iam::123456789012:role/RunbookAssumeRole"} `
-AutomationTargetParameterName "target parameter" `
-ScheduleExpression "cron or rate expression" `
-TargetLocations @{
  "Accounts"=["111122223333,444455556666,444455556666"],
  "Regions"=["region,region"]
```

The command returns details for the new association similar to the following.

## Linux & macOS

```
{
  "AssociationDescription": {
    "ScheduleExpression": "cron(0 7 ? * MON *)",
    "Name": "AWS-StartEC2Instance",
    "Parameters": {
      "AutomationAssumeRole": [
        "arn:aws:iam::123456789012:role/RunbookAssumeRole"
      ]

### Note

If you use tags to create an association on one or more target instances, and then you remove the tags from an instance, that instance no longer runs the association. The instance is disassociated from the State Manager document.

## Troubleshooting automations run by State Manager associations

Systems Manager Automation enforces a limit of 100 concurrent automations, and 1,000 queued automations per account, per Region. If a State Manager association that uses a runbook shows a status of **Failed** and a detailed status of **AutomationExecutionLimitExceeded**, then your automation might have reached the limit. As a result, Systems Manager throttles the automations. To resolve this issue, do the following:

- Use a different rate or cron expression for your association. For example, if the association is scheduled to run every 30 minutes, then change the expression so that it runs every hour or two.
- Delete existing automations that have a status of **Pending**. By deleting these automations, you clear the current queue.

## Schedule automations with maintenance windows

You can start an automation by configuring a runbook as a registered task for a maintenance window. By registering the runbook as a registered task, the maintenance window runs the automation during the scheduled maintenance period.

For example, let's say you create a runbook named `CreateAMI` that creates an Amazon Machine Image (AMI) of instances registered as targets to the maintenance window. To specify the `CreateAMI` runbook (and corresponding automation) as a registered task of a maintenance window, you first create a maintenance window and register targets. Then you use the following procedure to specify the `CreateAMI` document as a registered task within the maintenance window. When the maintenance window starts during the scheduled period, the system runs the automation and creates an AMI of the registered targets.

For information about creating Automation runbooks, see [Creating your own runbooks](#). Automation is a capability of AWS Systems Manager.

Use the following procedures to configure an automation as a registered task for a maintenance window using the AWS Systems Manager console, AWS Command Line Interface (AWS CLI), or AWS Tools for Windows PowerShell.

### Registering an automation task to a maintenance window (console)

The following procedure describes how to use the Systems Manager console to configure an automation as a registered task for a maintenance window.

#### Before you begin

Before you complete the following procedure, you must create a maintenance window and register at least one target. For more information, see the following procedures:

- [Create a maintenance window using the console](#).
- [Assign targets to a maintenance window using the console](#)

### To configure an automation as a registered task for a maintenance window

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the left navigation pane, choose **Maintenance Windows**, and then choose the maintenance window you want to register an Automation task with.

3. Choose **Actions**. Then choose **Register Automation task** to run your choice of an automation on targets by using a runbook.
4. For **Name**, enter a name for the task.
5. For **Description**, enter a description.
6. For **Document**, choose the runbook that defines the tasks to run.
7. For **Document version**, choose the runbook version to use.
8. For **Task priority**, specify a priority for this task. 1 is the highest priority. Tasks in a maintenance window are scheduled in priority order; tasks that have the same priority are scheduled in parallel.
9. In the **Targets** section, if the runbook you chose is one that runs tasks on resources, identify the targets on which you want to run this automation by specifying tags or by selecting instances manually.

 **Note**

If you want to pass the resources through input parameters instead of targets, you don't need to specify a maintenance window target.

In many cases, you don't need to explicitly specify a target for an automation task. For example, say that you're creating an Automation-type task to update an Amazon Machine Image (AMI) for Linux using the `AWS-UpdateLinuxAmi` runbook. When the task runs, the AMI is updated with the latest available Linux distribution packages and Amazon software. New instances created from the AMI already have these updates installed. Because the ID of the AMI to be updated is specified in the input parameters for the runbook, there is no need to specify a target again in the maintenance window task.

For information about maintenance window tasks that don't require targets, see [the section called "Registering maintenance window tasks without targets"](#).

10. (Optional) For **Rate control**:

**Note**

If the task you're running doesn't specify targets, you don't need to specify rate controls.

- For **Concurrency**, specify either a number or a percentage of targets on which to run the automation at the same time.

If you selected targets by choosing tag key-value pairs, and you aren't certain how many targets use the selected tags, then limit the number of automations that can run at the same time by specifying a percentage.

When the maintenance window runs, a new automation is initiated per target. There is a limit of 100 concurrent automations per AWS account. If you specify a concurrency rate greater than 100, concurrent automations greater than 100 are automatically added to the automation queue. For information, see [Systems Manager service quotas](#) in the *Amazon Web Services General Reference*.

- For **Error threshold**, specify when to stop running the automation on other targets after it fails on either a number or a percentage of targets. For example, if you specify three errors, then Systems Manager stops running automations when the fourth error is received. Targets still processing the automation might also send errors.

11. In the **Input Parameters** section, specify parameters for the runbook. For runbooks, the system auto-populates some of the values. You can keep or replace these values.

**Important**

For runbooks, you can optionally specify an Automation Assume Role. If you don't specify a role for this parameter, then the automation assumes the maintenance window service role you choose in step 11. As such, you must ensure that the maintenance window service role you choose has the appropriate AWS Identity and Access Management (IAM) permissions to perform the actions defined within the runbook.

For example, the service-linked role for Systems Manager doesn't have the IAM permission `ec2:CreateSnapshot`, which is required to use the runbook `AWS-CopySnapshot`. In this scenario, you must either use a custom maintenance window

service role or specify an Automation assume role that has `ec2:CreateSnapshot` permissions. For information, see [Setting up Automation](#).

12. In the **IAM service role** area, choose a role to provide permissions for Systems Manager to start the automation.

To create a service role for maintenance window tasks, see [Setting up Maintenance Windows](#).

13. Choose **Register Automation task**.

## Registering an Automation task to a maintenance window (command line)

The following procedure describes how to use the AWS CLI (on Linux or Windows) or AWS Tools for PowerShell to configure an automation as a registered task for a maintenance window.

### Before you begin

Before you complete the following procedure, you must create a maintenance window and register at least one target. For more information, see the following procedures:

- [Step 1: Create the maintenance window using the AWS CLI](#).
- [Step 2: Register a target node with the maintenance window using the AWS CLI](#)

## To configure an automation as a registered task for a maintenance window

1. Install and configure the AWS CLI or the AWS Tools for PowerShell, if you haven't already.

For information, see [Installing or updating the latest version of the AWS CLI](#) and [Installing the AWS Tools for PowerShell](#).

2. Create a command to configure an automation as a registered task for a maintenance window. Replace each *example resource placeholder* with your own information.

### Linux & macOS

```
aws ssm register-task-with-maintenance-window \  
--window-id window ID \  
--name task name \  
--task-arn runbook name \  
--targets Key=targets,Values=value \  
--service-role-arn IAM role arn \  

```

```
--task-type AUTOMATION \
--task-invocation-parameters task parameters \
--priority task priority \
--max-concurrency 10% \
--max-errors 5
```

### Note

If you configure an automation as a registered task by using the AWS CLI, use the `--Task-Invocation-Parameters` parameter to specify parameters to pass to a task when it runs. Don't use the `--Task-Parameters` parameter. The `--Task-Parameters` parameter is a legacy parameter.

For maintenance window tasks without a target specified, you can't supply values for `--max-errors` and `--max-concurrency`. Instead, the system inserts a placeholder value of 1, which might be reported in the response to commands such as [describe-maintenance-window-tasks](#) and [get-maintenance-window-task](#). These values don't affect the running of your task and can be ignored.

For information about maintenance window tasks that don't require targets, see [Registering maintenance window tasks without targets](#).

## Windows

```
aws ssm register-task-with-maintenance-window ^
--window-id window ID ^
--name task name ^
--task-arn runbook name ^
--targets Key=targets,Values=value ^
--service-role-arn IAM role arn ^
--task-type AUTOMATION ^
--task-invocation-parameters task parameters ^
--priority task priority ^
--max-concurrency 10% ^
--max-errors 5
```

### Note

If you configure an automation as a registered task by using the AWS CLI, use the `--task-invocation-parameters` parameter to specify parameters to pass to

a task when it runs. Don't use the `--task-parameters` parameter. The `--task-parameters` parameter is a legacy parameter.

For maintenance window tasks without a target specified, you can't supply values for `--max-errors` and `--max-concurrency`. Instead, the system inserts a placeholder value of 1, which might be reported in the response to commands such as [describe-maintenance-window-tasks](#) and [get-maintenance-window-task](#). These values don't affect the running of your task and can be ignored.

For information about maintenance window tasks that don't require targets, see [Registering maintenance window tasks without targets](#).

## PowerShell

```
Register-SSMTaskWithMaintenanceWindow `
-WindowId window ID `
-Name "task name" `
-TaskArn "runbook name" `
-Target @{ Key="targets";Values="value" } `
-ServiceRoleArn "IAM role arn" `
-TaskType "AUTOMATION" `
-Automation_Parameter @{ "task parameter"="task parameter value"} `
-Priority task priority `
-MaxConcurrency 10% `
-MaxError 5
```

### Note

If you configure an automation as a registered task by using the AWS Tools for PowerShell, use the `-Automation_Parameter` parameter to specify parameters to pass to a task when the task runs. Don't use the `-TaskParameters` parameter. The `-TaskParameters` parameter is a legacy parameter.

For maintenance window tasks without a target specified, you can't supply values for `-MaxError` and `-MaxConcurrency`. Instead, the system inserts a placeholder value of 1, which might be reported in the response to commands such as `Get-SSMMaintenanceWindowTaskList` and `Get-SSMMaintenanceWindowTask`. These values don't affect the running of your task and can be ignored.

For information about maintenance window tasks that don't require targets, see [Registering maintenance window tasks without targets](#).

The following example configures an automation as a registered task to a maintenance window with priority 1. It also demonstrates omitting the `--targets`, `--max-errors`, and `--max-concurrency` options for a targetless maintenance window task. The automation uses the `AWS-StartEC2Instance` runbook and the specified Automation assume role to start EC2 instances registered as targets to the maintenance window. The maintenance window runs the automation simultaneously on 5 instances maximum at any given time. Also, the registered task stops running on more instances for a particular interval if the error count exceeds 1.

## Linux & macOS

```
aws ssm register-task-with-maintenance-window \
--window-id mw-0c50858d01EXAMPLE \
--name StartEC2Instances \
--task-arn AWS-StartEC2Instance \
--service-role-arn arn:aws:iam::123456789012:role/MaintenanceWindowRole \
--task-type AUTOMATION \
--task-invocation-parameters "{\"Automation\":{\"Parameters\":{\"InstanceId\":
[\"{{TARGET_ID}}\"],\"AutomationAssumeRole\":[\"arn:aws:iam::123456789012:role/
AutomationAssumeRole\"]}}}" \
--priority 1
```

## Windows

```
aws ssm register-task-with-maintenance-window ^
--window-id mw-0c50858d01EXAMPLE ^
--name StartEC2Instances ^
--task-arn AWS-StartEC2Instance ^
--service-role-arn arn:aws:iam::123456789012:role/MaintenanceWindowRole ^
--task-type AUTOMATION ^
--task-invocation-parameters "{\"Automation\":{\"Parameters\":{\"InstanceId\":
[\"{{TARGET_ID}}\"],\"AutomationAssumeRole\":[\"arn:aws:iam::123456789012:role/
AutomationAssumeRole\"]}}}" ^
--priority 1
```

## PowerShell

```
Register-SSMTaskWithMaintenanceWindow `
-WindowId mw-0c50858d01EXAMPLE `
-Name "StartEC2" `
-TaskArn "AWS-StartEC2Instance" `
-ServiceRoleArn "arn:aws:iam::123456789012:role/MaintenanceWindowRole" `
-TaskType "AUTOMATION" `
-Automation_Parameter
@{ "InstanceId"="{{TARGET_ID}}";"AutomationAssumeRole"="arn:aws:iam::123456789012:role/
AutomationAssumeRole" } `
-Priority 1
```

The command returns details for the new registered task similar to the following.

## Linux & macOS

```
{
  "WindowTaskId": "4f7ca192-7e9a-40fe-9192-5cb15EXAMPLE"
}
```

## Windows

```
{
  "WindowTaskId": "4f7ca192-7e9a-40fe-9192-5cb15EXAMPLE"
}
```

## PowerShell

```
4f7ca192-7e9a-40fe-9192-5cb15EXAMPLE
```

3. To view the registered task, run the following command. Replace *maintenance windows ID* with your own information.

## Linux & macOS

```
aws ssm describe-maintenance-window-tasks \
--window-id maintenance window ID
```

## Windows

```
aws ssm describe-maintenance-window-tasks ^  
--window-id maintenance window ID
```

## PowerShell

```
Get-SSMMaintenanceWindowTaskList `   
-WindowId maintenance window ID
```

The system returns information like the following.

## Linux & macOS

```
{  
  "Tasks": [  
    {  
      "ServiceRoleArn": "arn:aws:iam::123456789012:role/  
MaintenanceWindowRole",  
      "MaxErrors": "1",  
      "TaskArn": "AWS-StartEC2Instance",  
      "MaxConcurrency": "1",  
      "WindowTaskId": "4f7ca192-7e9a-40fe-9192-5cb15EXAMPLE",  
      "TaskParameters": {},  
      "Priority": 1,  
      "WindowId": "mw-0c50858d01EXAMPLE",  
      "Type": "AUTOMATION",  
      "Targets": [  
      ],  
      "Name": "StartEC2"  
    }  
  ]  
}
```

## Windows

```
{  
  "Tasks": [  
    {
```

```

        "ServiceRoleArn": "arn:aws:iam::123456789012:role/
MaintenanceWindowRole",
        "MaxErrors": "1",
        "TaskArn": "AWS-StartEC2Instance",
        "MaxConcurrency": "1",
        "WindowTaskId": "4f7ca192-7e9a-40fe-9192-5cb15EXAMPLE",
        "TaskParameters": {},
        "Priority": 1,
        "WindowId": "mw-0c50858d01EXAMPLE",
        "Type": "AUTOMATION",
        "Targets": [
        ],
        "Name": "StartEC2"
    }
]
}

```

## PowerShell

```

Description      :
LoggingInfo     :
MaxConcurrency   : 5
MaxErrors       : 1
Name            : StartEC2
Priority        : 1

```

## Systems Manager Automation actions reference

This reference describes the Automation actions that you can specify in an Automation runbook. Automation is a capability of AWS Systems Manager. These actions can't be used in other types of Systems Manager (SSM) documents. For information about plugins for other types of SSM documents, see [Command document plugin reference](#).

Systems Manager Automation runs steps defined in Automation runbooks. Each step is associated with a particular action. The action determines the inputs, behavior, and outputs of the step. Steps are defined in the `mainSteps` section of your runbook.

You don't need to specify the outputs of an action or step. The outputs are predetermined by the action associated with the step. When you specify step inputs in your runbooks, you can reference one or more outputs from an earlier step. For example, you can make the output of `aws:runInstances` available for a subsequent `aws:runCommand` action. You can also reference outputs from earlier steps in the `Output` section of the runbook.

### Important

If you run an automation workflow that invokes other services by using an AWS Identity and Access Management (IAM) service role, be aware that the service role must be configured with permission to invoke those services. This requirement applies to all AWS Automation runbooks (AWS- \* runbooks) such as the `AWS-ConfigureS3BucketLogging`, `AWS-CreateDynamoDBBackup`, and `AWS-RestartEC2Instance` runbooks, to name a few. This requirement also applies to any custom Automation runbooks you create that invoke other AWS services by using actions that call other services. For example, if you use the `aws:executeAwsApi`, `aws:createStack`, or `aws:copyImage` actions, configure the service role with permission to invoke those services. You can give permissions to other AWS services by adding an IAM inline policy to the role. For more information, see [\(Optional\) Add an Automation inline policy or customer managed policy to invoke other AWS services](#).

## Topics

- [Properties shared by all actions](#)
- [aws:approve – Pause an automation for manual approval](#)
- [aws:assertAwsResourceProperty – Assert an AWS resource state or event state](#)
- [aws:branch – Run conditional automation steps](#)
- [aws:changeInstanceState – Change or assert instance state](#)
- [aws:copyImage – Copy or encrypt an Amazon Machine Image](#)
- [aws:createImage – Create an Amazon Machine Image](#)
- [aws:createStack – Create an AWS CloudFormation stack](#)
- [aws:createTags – Create tags for AWS resources](#)

- [aws:deleteImage](#) – Delete an Amazon Machine Image
- [aws:deleteStack](#) – Delete an AWS CloudFormation stack
- [aws:executeAutomation](#) – Run another automation
- [aws:executeAwsApi](#) – Call and run AWS API operations
- [aws:executeScript](#) – Run a script
- [aws:executeStateMachine](#) – Run an AWS Step Functions state machine
- [aws:invokeWebhook](#) – Invoke an Automation webhook integration
- [aws:invokeLambdaFunction](#) – Invoke an AWS Lambda function
- [aws:loop](#) – Iterate over steps in an automation
- [aws:pause](#) – Pause an automation
- [aws:runCommand](#) – Run a command on a managed instance
- [aws:runInstances](#) – Launch an Amazon EC2 instance
- [aws:sleep](#) – Delay an automation
- [aws:updateVariable](#) – Updates a value for a runbook variable
- [aws:waitForAwsResourceProperty](#) – Wait on an AWS resource property
- [Automation system variables](#)

## Properties shared by all actions

Common properties are parameters or options that are found in all actions. Some options define behavior for a step, such as how long to wait for a step to complete and what to do if the step fails. The following properties are common to all actions.

### [description](#)

Information you provide to describe the purpose of a runbook or a step.

Type: String

Required: No

### [name](#)

An identifier that must be unique across all step names in the runbook.

Type: String

Allowed pattern: `[a-zA-Z0-9_]+$`

Required: Yes

### [action](#)

The name of the action the step is to run. [aws:runCommand – Run a command on a managed instance](#) is an example of an action you can specify here. This document provides detailed information about all available actions.

Type: String

Required: Yes

### [maxAttempts](#)

The number of times the step should be retried in case of failure. If the value is greater than 1, the step isn't considered to have failed until all retry attempts have failed. The default value is 1.

Type: Integer

Required: No

### [timeoutSeconds](#)

The timeout value for the step. If the timeout is reached and the value of `maxAttempts` is greater than 1, then the step isn't considered to have timed out until all retries have been attempted.

Type: Integer

Required: No

### [onFailure](#)

Indicates whether the automation should stop, continue, or go to a different step on failure. The default value for this option is `abort`.

Type: String

Valid values: `Abort` | `Continue` | `step:step_name`

Required: No

### [onCancel](#)

Indicates which step the automation should go to in the event that a user cancels the automation. Automation runs the cancellation workflow for a maximum of two minutes.

Type: String

Valid values: Abort | step:*step\_name*

Required: No

The `onCancel` property doesn't support moving to the following actions:

- `aws:approve`
- `aws:copyImage`
- `aws:createImage`
- `aws:createStack`
- `aws:createTags`
- `aws:loop`
- `aws:pause`
- `aws:runInstances`
- `aws:sleep`

### [isEnd](#)

This option stops an automation at the end of a specific step. The automation stops if the step failed or succeeded. The default value is false.

Type: Boolean

Valid values: true | false

Required: No

### [nextStep](#)

Specifies which step in an automation to process next after successfully completing a step.

Type: String

Required: No

### [isCritical](#)

Designates a step as critical for the successful completion of the Automation. If a step with this designation fails, then Automation reports the final status of the Automation as Failed. This property is only evaluated if you explicitly define it in your step. If the `onFailure` property

is set to Continue in a step, the value defaults to false. Otherwise, the default value for this option is true.

Type: Boolean

Valid values: true | false

Required: No

### inputs

The properties specific to the action.

Type: Map

Required: Yes

### Example

```
---
description: "Custom Automation Example"
schemaVersion: '0.3'
assumeRole: "{{ AutomationAssumeRole }}"
parameters:
  AutomationAssumeRole:
    type: String
    description: "(Required) The ARN of the role that allows Automation to perform
      the actions on your behalf. If no role is specified, Systems Manager Automation
      uses your IAM permissions to run this runbook."

## aws:approve – Pause an automation for manual approval

Temporarily pauses an automation until designated principals either approve or reject the action. After the required number of approvals is reached, the automation resumes. You can insert the approval step any place in the `mainSteps` section of your runbook.

### Note

This action doesn't support multi-account and Region automations. The default timeout for this action is 7 days (604800 seconds) and the maximum value is 30 days (2592000 seconds). You can limit or extend the timeout by specifying the `timeoutSeconds` parameter for an `aws:approve` step.

In the following example, the `aws:approve` action temporarily pauses the automation until one approver either accepts or rejects the automation. Upon approval, the automation runs a simple PowerShell command.

### YAML

```
---
description: RunInstancesDemo1
schemaVersion: '0.3'
assumeRole: "{{ assumeRole }}"
parameters:
  assumeRole:
    type: String
  message:
    type: String
mainSteps:
- name: approve
  action: aws:approve
  timeoutSeconds: 1000
  onFailure: Abort
  inputs:
    NotificationArn: arn:aws:sns:us-east-2:12345678901:AutomationApproval
    Message: "{{ message }}"
    MinRequiredApprovals: 1
    Approvers:
```

```

- arn:aws:iam::12345678901:user/AWS-User-1
- name: run
  action: aws:runCommand
  inputs:
    InstanceIds:
    - i-1a2b3c4d5e6f7g
    DocumentName: AWS-RunPowerShellScript
    Parameters:
      commands:
      - date

```

## JSON

```

{
  "description": "RunInstancesDemo1",
  "schemaVersion": "0.3",
  "assumeRole": "[{ assumeRole }]",
  "parameters": {
    "assumeRole": {
      "type": "String"
    },
    "message": {
      "type": "String"
    }
  },
  "mainSteps": [
    {
      "name": "approve",
      "action": "aws:approve",
      "timeoutSeconds": 1000,
      "onFailure": "Abort",
      "inputs": {
        "NotificationArn": "arn:aws:sns:us-
east-2:12345678901:AutomationApproval",
        "Message": "[{ message }]",
        "MinRequiredApprovals": 1,
        "Approvers": [
          "arn:aws:iam::12345678901:user/AWS-User-1"
        ]
      }
    },
    {
      "name": "run",

```

```

    "action": "aws:runCommand",
    "inputs": {
      "InstanceIds": [
        "i-1a2b3c4d5e6f7g"
      ],
      "DocumentName": "AWS-RunPowerShellScript",
      "Parameters": {
        "commands": [
          "date"
        ]
      }
    }
  ]
}

```

You can approve or deny Automations that are waiting for approval in the console.

### To approve or deny waiting Automations

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Automation**.
3. Choose the option next to an Automation with a status of **Waiting**.

The screenshot shows the 'Automation executions' page in the AWS Systems Manager console. At the top right, there are buttons for 'View details', 'Cancel execution', and 'Approve/Deny'. The 'Approve/Deny' button is highlighted with a red border. Below the buttons is a search bar and a table of automation executions.

| Execution ID                         | Document name                      | Status  | Start time (UTC)              | End time (UTC) |
|--------------------------------------|------------------------------------|---------|-------------------------------|----------------|
| 7e4e1ea9-f186-11e7-9a57-e1a762426a2a | AWS-RestartEC2InstanceWithApproval | Waiting | Thu, 04 Jan 2018 19:36:00 GMT | -              |

4. Choose **Approve/Deny**.
5. Review the details of the Automation.
6. Choose either **Approve** or **Deny**, type an optional comment, and then choose **Submit**.

### Input example

## YAML

```
NotificationArn: arn:aws:sns:us-west-1:12345678901:Automation-ApprovalRequest
Message: Please approve this step of the Automation.
MinRequiredApprovals: 3
Approvers:
- IamUser1
- IamUser2
- arn:aws:iam::12345678901:user/IamUser3
- arn:aws:iam::12345678901:role/IamRole
```

## JSON

```
{
  "NotificationArn": "arn:aws:sns:us-west-1:12345678901:Automation-ApprovalRequest",
  "Message": "Please approve this step of the Automation.",
  "MinRequiredApprovals": 3,
  "Approvers": [
    "IamUser1",
    "IamUser2",
    "arn:aws:iam::12345678901:user/IamUser3",
    "arn:aws:iam::12345678901:role/IamRole"
  ]
}
```

## NotificationArn

The Amazon Resource Name (ARN) of an Amazon Simple Notification Service (Amazon SNS) topic for Automation approvals. When you specify an `aws:approve` step in a runbook, Automation sends a message to this topic letting principals know that they must either approve or reject an Automation step. The title of the Amazon SNS topic must be prefixed with "Automation".

Type: String

Required: No

## Message

The information you want to include in the Amazon SNS topic when the approval request is sent. The maximum message length is 4096 characters.

Type: String

Required: No

### MinRequiredApprovals

The minimum number of approvals required to resume the automation. If you don't specify a value, the system defaults to one. The value for this parameter must be a positive number. The value for this parameter can't exceed the number of approvers defined by the `Approvers` parameter.

Type: Integer

Required: No

### Approvers

A list of AWS authenticated principals who are able to either approve or reject the action. The maximum number of approvers is 10. You can specify principals by using any of the following formats:

- A user name
- A user ARN
- An IAM role ARN
- An IAM assume role ARN

Type: StringList

Required: Yes

### EnhancedApprovals

This input is only used for Change Manager templates. A list of AWS authenticated principals who are able to either approve or reject the action, the type of IAM principal, and the minimum number of approvers. The following is an example:

```
schemaVersion: "0.3"
emergencyChange: false
autoApprovable: false
mainSteps:
  - name: ApproveAction1
    action: aws:approve
    timeoutSeconds: 604800
```

```
inputs:
  Message: Please approve this change request
  MinRequiredApprovals: 3
  EnhancedApprovals:
  Approvers:
    - approver: John Stiles
      type: IamUser
      minRequiredApprovals: 0
    - approver: Ana Carolina Silva
      type: IamUser
      minRequiredApprovals: 0
    - approver: GroupOfThree
      type: IamGroup
      minRequiredApprovals: 0
    - approver: RoleOfTen
      type: IamRole
      minRequiredApprovals: 0
```

Type: StringList

Required: Yes

## Output

### ApprovalStatus

The approval status of the step. The status can be one of the following: Approved, Rejected, or Waiting. Waiting means that Automation is waiting for input from approvers.

Type: String

### ApproverDecisions

A JSON map that includes the approval decision of each approver.

Type: MapList

## **aws:assertAwsResourceProperty – Assert an AWS resource state or event state**

The `aws:assertAwsResourceProperty` action allows you to assert a specific resource state or event state for a specific Automation step.

For more examples of how to use this action, see [Additional runbook examples](#).

## Input

Inputs are defined by the API operation that you choose.

## YAML

```
action: aws:assertAwsResourceProperty
inputs:
  Service: The official namespace of the service
  Api: The API operation or method name
  API operation inputs or parameters: A value
  PropertySelector: Response object
  DesiredValues:
    - Desired property values
```

## JSON

```
{
  "action": "aws:assertAwsResourceProperty",
  "inputs": {
    "Service": "The official namespace of the service",
    "Api": "The API operation or method name",
    "API operation inputs or parameters": "A value",
    "PropertySelector": "Response object",
    "DesiredValues": [
      "Desired property values"
    ]
  }
}
```

## Service

The AWS service namespace that contains the API operation that you want to run. For example, the namespace for Systems Manager is `ssm`. The namespace for Amazon EC2 is `ec2`. You can view a list of supported AWS service namespaces in the [Available Services](#) section of the *AWS CLI Command Reference*.

Type: String

Required: Yes

## Api

The name of the API operation that you want to run. You can view the API operations (also called methods) by choosing a service in the left navigation on the following [Services Reference](#) page. Choose a method in the **Client** section for the service that you want to invoke. For example, all API operations (methods) for Amazon Relational Database Service (Amazon RDS) are listed on the following page: [Amazon RDS methods](#).

Type: String

Required: Yes

### API operation inputs

One or more API operation inputs. You can view the available inputs (also called parameters) by choosing a service in the left navigation on the following [Services Reference](#) page. Choose a method in the **Client** section for the service that you want to invoke. For example, all methods for Amazon RDS are listed on the following page: [Amazon RDS methods](#). Choose the [describe\\_db\\_instances](#) method and scroll down to see the available parameters, such as **DBInstanceIdentifier**, **Name**, and **Values**. Use the following format to specify more than one input.

### YAML

```
inputs:
  Service: The official namespace of the service
  Api: The API operation name
  API input 1: A value
  API Input 2: A value
  API Input 3: A value
```

### JSON

```
"inputs":{
  "Service":"The official namespace of the service",
  "Api":"The API operation name",
  "API input 1":"A value",
  "API Input 2":"A value",
  "API Input 3":"A value"
}
```

Type: Determined by chosen API operation

Required: Yes

### PropertySelector

The JSONPath to a specific attribute in the response object. You can view the response objects by choosing a service in the left navigation on the following [Services Reference](#) page. Choose a method in the **Client** section for the service that you want to invoke. For example, all methods for Amazon RDS are listed on the following page: [Amazon RDS methods](#). Choose the [describe\\_db\\_instances](#) method and scroll down to the **Response Structure** section. **DBInstances** is listed as a response object.

Type: String

Required: Yes

### DesiredValues

The expected status or state on which to continue the automation. If you specify a Boolean value, you must use a capital letter such as True or False.

Type: StringList

Required: Yes

## **aws:branch – Run conditional automation steps**

The `aws:branch` action allows you to create a dynamic automation that evaluates different choices in a single step and then jumps to a different step in the runbook based on the results of that evaluation.

When you specify the `aws:branch` action for a step, you specify `Choices` that the automation must evaluate. The `Choices` can be based on either a value that you specified in the `Parameters` section of the runbook, or a dynamic value generated as the output from the previous step. The automation evaluates each choice by using a Boolean expression. If the first choice is true, then the automation jumps to the step designated for that choice. If the first choice is false, the automation evaluates the next choice. The automation continues evaluating each choice until it process a true choice. The automation then jumps to the designated step for the true choice.

If none of the choices are true, the automation checks to see if the step contains a `default` value. A default value defines a step that the automation should jump to if none of the choices are true. If no `default` value is specified for the step, then the automation processes the next step in the runbook.

The `aws:branch` action supports complex choice evaluations by using a combination of `And`, `Not`, and `Or` operators. For more information about how to use `aws:branch`, including example runbooks and examples that use different operators, see [Using conditional statements in runbooks](#).

## Input

Specify one or more Choices in a step. The Choices can be based on either a value that you specified in the Parameters section of the runbook, or a dynamic value generated as the output from the previous step. Here is a YAML sample that evaluates a parameter.

```
mainSteps:
- name: chooseOS
  action: aws:branch
  inputs:
    Choices:
      - NextStep: runWindowsCommand
        Variable: "{{Name of a parameter defined in the Parameters section. For example: OS_name}}"
        StringEquals: windows
      - NextStep: runLinuxCommand
        Variable: "{{Name of a parameter defined in the Parameters section. For example: OS_name}}"
        StringEquals: linux
    Default:
      sleep3
```

Here is a YAML sample that evaluates output from a previous step.

```
mainSteps:
- name: chooseOS
  action: aws:branch
  inputs:
    Choices:
      - NextStep: runPowerShellCommand
        Variable: "{{Name of a response object. For example: GetInstance.platform}}"
        StringEquals: Windows
      - NextStep: runShellCommand
        Variable: "{{Name of a response object. For example: GetInstance.platform}}"
        StringEquals: Linux
    Default:
      sleep3
```

## Choices

One or more expressions that the Automation should evaluate when determining the next step to process. Choices are evaluated by using a Boolean expression. Each choice must define the following options:

- **NextStep:** The next step in the runbook to process if the designated choice is true.
- **Variable:** Specify either the name of a parameter that is defined in the Parameters section of the runbook. Or specify an output object from a previous step in the runbook. For more information about creating variables for `aws:branch`, see [About creating the output variable](#).
- **Operation:** The criteria used to evaluate the choice. The `aws:branch` action supports the following operations:

### String operations

- `StringEquals`
- `EqualsIgnoreCase`
- `StartsWith`
- `EndsWith`
- `Contains`

### Numeric operations

- `NumericEquals`
- `NumericGreater`
- `NumericLesser`
- `NumericGreaterOrEquals`
- `NumericLesser`
- `NumericLesserOrEquals`

### Boolean operation

- `BooleanEquals`

**⚠ Important**

When you create a runbook, the system validates each operation in the runbook. If an operation isn't supported, the system returns an error when you try to create the runbook.

**Default**

The name of a step the automation should jump to if none of the Choices are true.

Type: String

Required: No

**ℹ Note**

The `aws:branch` action supports `And`, `Or`, and `Not` operators. For examples of `aws:branch` that use operators, see [Using conditional statements in runbooks](#).

**aws:changeInstanceState – Change or assert instance state**

Changes or asserts the state of the instance.

This action can be used in assert mode (doesn't run the API to change the state but verifies the instance is in the desired state.) To use assert mode, set the `CheckStateOnly` parameter to `true`. This mode is useful when running the `Sysprep` command on Windows, which is an asynchronous command that can run in the background for a long time. You can ensure that the instance is stopped before you create an Amazon Machine Image (AMI).

**ℹ Note**

The default timeout value for this action is 3600 seconds (one hour). You can limit or extend the timeout by specifying the `timeoutSeconds` parameter for an `aws:changeInstanceState` step.

**Input**

## YAML

```
name: stopMyInstance
action: aws:changeInstanceState
maxAttempts: 3
timeoutSeconds: 3600
onFailure: Abort
inputs:
  InstanceIds:
  - i-1234567890abcdef0
  CheckStateOnly: true
  DesiredState: stopped
```

## JSON

```
{
  "name": "stopMyInstance",
  "action": "aws:changeInstanceState",
  "maxAttempts": 3,
  "timeoutSeconds": 3600,
  "onFailure": "Abort",
  "inputs": {
    "InstanceIds": ["i-1234567890abcdef0"],
    "CheckStateOnly": true,
    "DesiredState": "stopped"
  }
}
```

### InstanceIds

The IDs of the instances.

Type: StringList

Required: Yes

### CheckStateOnly

If false, sets the instance state to the desired state. If true, asserts the desired state using polling.

Default: false

Type: Boolean

Required: No

### DesiredState

The desired state. When set to `running`, this action waits for the Amazon EC2 state to be `Running`, the Instance Status to be `OK`, and the System Status to be `OK` before completing.

Type: String

Valid values: `running` | `stopped` | `terminated`

Required: Yes

### Force

If set, forces the instances to stop. The instances don't have an opportunity to flush file system caches or file system metadata. If you use this option, you must perform file system check and repair procedures. This option isn't recommended for EC2 instances for Windows Server.

Type: Boolean

Required: No

### AdditionalInfo

Reserved.

Type: String

Required: No

## Output

None

### **aws : copyImage – Copy or encrypt an Amazon Machine Image**

Copies an Amazon Machine Image (AMI) from any AWS Region into the current Region. This action can also encrypt the new AMI.

## Input

This action supports most CopyImage parameters. For more information, see [CopyImage](#).

The following example creates a copy of an AMI in the Seoul region (SourceImageID: ami-0fe10819. SourceRegion: ap-northeast-2). The new AMI is copied to the region where you initiated the Automation action. The copied AMI will be encrypted because the optional Encrypted flag is set to true.

## YAML

```
name: createEncryptedCopy
action: aws:copyImage
maxAttempts: 3
onFailure: Abort
inputs:
  SourceImageId: ami-0fe10819
  SourceRegion: ap-northeast-2
  ImageName: Encrypted Copy of LAMP base AMI in ap-northeast-2
  Encrypted: true
```

## JSON

```
{
  "name": "createEncryptedCopy",
  "action": "aws:copyImage",
  "maxAttempts": 3,
  "onFailure": "Abort",
  "inputs": {
    "SourceImageId": "ami-0fe10819",
    "SourceRegion": "ap-northeast-2",
    "ImageName": "Encrypted Copy of LAMP base AMI in ap-northeast-2",
    "Encrypted": true
  }
}
```

## SourceRegion

The region where the source AMI exists.

Type: String

Required: Yes

## SourceImageId

The AMI ID to copy from the source Region.

Type: String

Required: Yes

## ImageName

The name for the new image.

Type: String

Required: Yes

## ImageDescription

A description for the target image.

Type: String

Required: No

## Encrypted

Encrypt the target AMI.

Type: Boolean

Required: No

## KmsKeyId

The full Amazon Resource Name (ARN) of the AWS KMS key to use when encrypting the snapshots of an image during a copy operation. For more information, see [CopyImage](#).

Type: String

Required: No

## ClientToken

A unique, case-sensitive identifier that you provide to ensure request idempotency. For more information, see [CopyImage](#).

Type: String

Required: No

## Output

### ImageId

The ID of the copied image.

### ImageState

The state of the copied image.

Valid values: available | pending | failed

## aws:createImage – Create an Amazon Machine Image

Creates an Amazon Machine Image (AMI) from an instance that is either running, stopping, or stopped, and polls for the ImageState to be available.

## Input

This action supports the following CreateImage parameters. For more information, see [CreateImage](#).

## YAML

```
name: createMyImage
action: aws:createImage
maxAttempts: 3
onFailure: Abort
inputs:
  InstanceId: i-1234567890abcdef0
  ImageName: AMI Created on{{global:DATE_TIME}}
  NoReboot: true
  ImageDescription: My newly created AMI
```

## JSON

```
{
  "name": "createMyImage",
  "action": "aws:createImage",
  "maxAttempts": 3,
```

```
"onFailure": "Abort",
"inputs": {
  "InstanceId": "i-1234567890abcdef0",
  "ImageName": "AMI Created on{{global:DATE_TIME}}",
  "NoReboot": true,
  "ImageDescription": "My newly created AMI"
}
}
```

## InstanceId

The ID of the instance.

Type: String

Required: Yes

## ImageName

The name for the image.

Type: String

Required: Yes

## ImageDescription

A description of the image.

Type: String

Required: No

## NoReboot

A Boolean literal.

By default, Amazon Elastic Compute Cloud (Amazon EC2) attempts to shut down and reboot the instance before creating the image. If the **No Reboot** option is set to `true`, Amazon EC2 doesn't shut down the instance before creating the image. When this option is used, file system integrity on the created image can't be guaranteed.

If you don't want the instance to run after you create an AMI from it, first use the [aws:changeInstanceState – Change or assert instance state](#) action to stop the instance, and then use this `aws:createImage` action with the **NoReboot** option set to `true`.

Type: Boolean

Required: No

### BlockDeviceMappings

The block devices for the instance.

Type: Map

Required: No

## Output

### ImageId

The ID of the newly created image.

Type: String

### ImageState

The current state of the image. If the state is available, the image is successfully registered and can be used to launch an instance.

Type: String

## aws:createStack – Create an AWS CloudFormation stack

Creates an AWS CloudFormation stack from a template.

For supplemental information about creating CloudFormation stacks, see [CreateStack](#) in the *AWS CloudFormation API Reference*.

## Input

### YAML

```
name: makeStack
action: aws:createStack
maxAttempts: 1
onFailure: Abort
inputs:
  Capabilities:
```

```

- CAPABILITY_IAM
StackName: myStack
TemplateURL: http://s3.amazonaws.com/amzn-s3-demo-bucket/myStackTemplate
TimeoutInMinutes: 5
Parameters:
  - ParameterKey: LambdaRoleArn
    ParameterValue: "{{LambdaAssumeRole}}"
  - ParameterKey: createdResource
    ParameterValue: createdResource-{{automation:EXECUTION_ID}}

```

## JSON

```

{
  "name": "makeStack",
  "action": "aws:createStack",
  "maxAttempts": 1,
  "onFailure": "Abort",
  "inputs": {
    "Capabilities": [
      "CAPABILITY_IAM"
    ],
    "StackName": "myStack",
    "TemplateURL": "http://s3.amazonaws.com/amzn-s3-demo-bucket/
myStackTemplate",
    "TimeoutInMinutes": 5,
    "Parameters": [
      {
        "ParameterKey": "LambdaRoleArn",
        "ParameterValue": "{{LambdaAssumeRole}}"
      },
      {
        "ParameterKey": "createdResource",
        "ParameterValue": "createdResource-{{automation:EXECUTION_ID}}"
      }
    ]
  }
}

```

## Capabilities

A list of values that you specify before CloudFormation can create certain stacks. Some stack templates include resources that can affect permissions in your AWS account. For those stacks, you must explicitly acknowledge their capabilities by specifying this parameter.

Valid values include `CAPABILITY_IAM`, `CAPABILITY_NAMED_IAM`, and `CAPABILITY_AUTO_EXPAND`.

### **CAPABILITY\_IAM and CAPABILITY\_NAMED\_IAM**

If you have IAM resources, you can specify either capability. If you have IAM resources with custom names, you must specify `CAPABILITY_NAMED_IAM`. If you don't specify this parameter, this action returns an `InsufficientCapabilities` error. The following resources require you to specify either `CAPABILITY_IAM` or `CAPABILITY_NAMED_IAM`.

- [AWS::IAM::AccessKey](#)
- [AWS::IAM::Group](#)
- [AWS::IAM::InstanceProfile](#)
- [AWS::IAM::Policy](#)
- [AWS::IAM::Role](#)
- [AWS::IAM::User](#)
- [AWS::IAM::UserToGroupAddition](#)

If your stack template contains these resources, we recommend that you review all permissions associated with them and edit their permissions, if necessary.

For more information, see [Acknowledging IAM Resources in AWS CloudFormation Templates](#).

### **CAPABILITY\_AUTO\_EXPAND**

Some template contain macros. Macros perform custom processing on templates; this can include simple actions like find-and-replace operations, all the way to extensive transformations of entire templates. Because of this, users typically create a change set from the processed template, so that they can review the changes resulting from the macros before actually creating the stack. If your stack template contains one or more macros, and you choose to create a stack directly from the processed template, without first reviewing the resulting changes in a change set, you must acknowledge this capability.

For more information, see [Using AWS CloudFormation Macros to Perform Custom Processing on Templates](#) in the *AWS CloudFormation User Guide*.

Type: array of Strings

Valid Values: `CAPABILITY_IAM` | `CAPABILITY_NAMED_IAM` | `CAPABILITY_AUTO_EXPAND`

Required: No

### ClientRequestToken

A unique identifier for this CreateStack request. Specify this token if you set maxAttempts in this step to a value greater than 1. By specifying this token, CloudFormation knows that you aren't attempting to create a new stack with the same name.

Type: String

Required: No

Length Constraints: Minimum length of 1. Maximum length of 128.

Pattern: [a-zA-Z0-9][-a-zA-Z0-9]\*

### DisableRollback

Set to true to turn off rollback of the stack if stack creation failed.

Conditional: You can specify either the DisableRollback parameter or the OnFailure parameter, but not both.

Default: false

Type: Boolean

Required: No

### NotificationARNs

The Amazon Simple Notification Service (Amazon SNS) topic ARNs for publishing stack-related events. You can find SNS topic ARNs using the Amazon SNS console, <https://console.aws.amazon.com/sns/v3/home>.

Type: array of Strings

Array Members: Maximum number of 5 items.

Required: No

### OnFailure

Determines the action to take if stack creation failed. You must specify DO\_NOTHING, ROLLBACK, or DELETE.

**Conditional:** You can specify either the `OnFailure` parameter or the `DisableRollback` parameter, but not both.

**Default:** `ROLLBACK`

**Type:** String

**Valid Values:** `DO_NOTHING` | `ROLLBACK` | `DELETE`

**Required:** No

## Parameters

A list of `Parameter` structures that specify input parameters for the stack. For more information, see the [Parameter](#) data type.

**Type:** array of [Parameter](#) objects

**Required:** No

## ResourceTypes

The template resource types that you have permissions to work with for this create stack action. For example: `AWS::EC2::Instance`, `AWS::EC2::*`, or `Custom::MyCustomInstance`. Use the following syntax to describe template resource types.

- For all AWS resources:

```
AWS::*
```

- For all custom resources:

```
Custom::*
```

- For a specific custom resource:

```
Custom::logical_ID
```

- For all resources of a particular AWS service:

```
AWS::service_name::*
```

- For a specific AWS resource:

```
AWS::service_name::resource_logical_ID
```

If the list of resource types doesn't include a resource that you're creating, the stack creation fails. By default, CloudFormation grants permissions to all resource types. IAM uses this parameter for CloudFormation-specific condition keys in IAM policies. For more information, see [Controlling Access with AWS Identity and Access Management](#).

Type: array of Strings

Length Constraints: Minimum length of 1. Maximum length of 256.

Required: No

### RoleARN

The Amazon Resource Name (ARN) of an IAM role that CloudFormation assumes to create the stack. CloudFormation uses the role's credentials to make calls on your behalf. CloudFormation always uses this role for all future operations on the stack. As long as users have permission to operate on the stack, CloudFormation uses this role even if the users don't have permission to pass it. Ensure that the role grants the least amount of privileges.

If you don't specify a value, CloudFormation uses the role that was previously associated with the stack. If no role is available, CloudFormation uses a temporary session that is generated from your user credentials.

Type: String

Length Constraints: Minimum length of 20. Maximum length of 2048.

Required: No

### StackName

The name that is associated with the stack. The name must be unique in the Region in which you're creating the stack.

#### Note

A stack name can contain only alphanumeric characters (case sensitive) and hyphens. It must start with an alphabetic character and can't be longer than 128 characters.

Type: String

Required: Yes

### StackPolicyBody

Structure containing the stack policy body. For more information, see [Prevent Updates to Stack Resources](#).

Conditional: You can specify either the StackPolicyBody parameter or the StackPolicyURL parameter, but not both.

Type: String

Length Constraints: Minimum length of 1. Maximum length of 16384.

Required: No

### StackPolicyURL

Location of a file containing the stack policy. The URL must point to a policy located in an S3 bucket in the same region as the stack. The maximum file size allowed for the stack policy is 16 KB.

Conditional: You can specify either the StackPolicyBody parameter or the StackPolicyURL parameter, but not both.

Type: String

Length Constraints: Minimum length of 1. Maximum length of 1350.

Required: No

### Tags

Key-value pairs to associate with this stack. CloudFormation also propagates these tags to the resources created in the stack. You can specify a maximum number of 10 tags.

Type: array of [Tag](#) objects

Required: No

### TemplateBody

Structure containing the template body with a minimum length of 1 byte and a maximum length of 51,200 bytes. For more information, see [Template Anatomy](#).

Conditional: You can specify either the `TemplateBody` parameter or the `TemplateURL` parameter, but not both.

Type: String

Length Constraints: Minimum length of 1.

Required: No

### TemplateURL

Location of a file containing the template body. The URL must point to a template that is located in an S3 bucket. The maximum size allowed for the template is 460,800 bytes. For more information, see [Template Anatomy](#).

Conditional: You can specify either the `TemplateBody` parameter or the `TemplateURL` parameter, but not both.

Type: String

Length Constraints: Minimum length of 1. Maximum length of 1024.

Required: No

### TimeoutInMinutes

The amount of time that can pass before the stack status becomes `CREATE_FAILED`. If `DisableRollback` isn't set or is set to `false`, the stack will be rolled back.

Type: Integer

Valid Range: Minimum value of 1.

Required: No

## Outputs

### StackId

Unique identifier of the stack.

Type: String

## StackStatus

Current status of the stack.

Type: String

Valid Values: CREATE\_IN\_PROGRESS | CREATE\_FAILED | CREATE\_COMPLETE  
| ROLLBACK\_IN\_PROGRESS | ROLLBACK\_FAILED | ROLLBACK\_COMPLETE  
| DELETE\_IN\_PROGRESS | DELETE\_FAILED | DELETE\_COMPLETE |  
UPDATE\_IN\_PROGRESS | UPDATE\_COMPLETE\_CLEANUP\_IN\_PROGRESS |  
UPDATE\_COMPLETE | UPDATE\_ROLLBACK\_IN\_PROGRESS | UPDATE\_ROLLBACK\_FAILED |  
UPDATE\_ROLLBACK\_COMPLETE\_CLEANUP\_IN\_PROGRESS | UPDATE\_ROLLBACK\_COMPLETE  
| REVIEW\_IN\_PROGRESS

Required: Yes

## StackStatusReason

Success or failure message associated with the stack status.

Type: String

Required: No

For more information, see [CreateStack](#).

## Security considerations

Before you can use the `aws:createStack` action, you must assign the following policy to the IAM Automation assume role. For more information about the assume role, see [Task 1: Create a service role for Automation](#).

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "sqs:*",
        "cloudformation:CreateStack",
        "cloudformation:DescribeStacks"
      ]
    }
  ]
}
```

```
        "Resource": "*"
      }
    ]
  }
```

## aws:createTags – Create tags for AWS resources

Creates new tags for Amazon Elastic Compute Cloud (Amazon EC2) instances or AWS Systems Manager managed instances.

### Input

This action supports most Amazon EC2 `CreateTags` and Systems Manager `AddTagsToResource` parameters. For more information, see [CreateTags](#) and [AddTagsToResource](#).

The following example shows how to tag an Amazon Machine Image (AMI) and an instance as production resources for a particular department.

### YAML

```
name: createTags
action: aws:createTags
maxAttempts: 3
onFailure: Abort
inputs:
  ResourceType: EC2
  ResourceIds:
    - ami-9a3768fa
    - i-02951acd5111a8169
  Tags:
    - Key: production
      Value: ''
    - Key: department
      Value: devops
```

### JSON

```
{
  "name": "createTags",
  "action": "aws:createTags",
  "maxAttempts": 3,
  "onFailure": "Abort",
```

```
"inputs": {
  "ResourceType": "EC2",
  "ResourceIds": [
    "ami-9a3768fa",
    "i-02951acd5111a8169"
  ],
  "Tags": [
    {
      "Key": "production",
      "Value": ""
    },
    {
      "Key": "department",
      "Value": "devops"
    }
  ]
}
```

## ResourceIds

The IDs of the resource(s) to be tagged. If resource type isn't "EC2", this field can contain only a single item.

Type: String List

Required: Yes

## Tags

The tags to associate with the resource(s).

Type: List of Maps

Required: Yes

## ResourceType

The type of resource(s) to be tagged. If not supplied, the default value of "EC2" is used.

Type: String

Required: No

Valid Values: EC2 | ManagedInstance | MaintenanceWindow | Parameter

## Output

None

### aws:deleteImage – Delete an Amazon Machine Image

Deletes the specified Amazon Machine Image (AMI) and all related snapshots.

## Input

This action supports only one parameter. For more information, see the documentation for [DeregisterImage](#) and [DeleteSnapshot](#).

## YAML

```
name: deleteMyImage
action: aws:deleteImage
maxAttempts: 3
timeoutSeconds: 180
onFailure: Abort
inputs:
  ImageId: ami-12345678
```

## JSON

```
{
  "name": "deleteMyImage",
  "action": "aws:deleteImage",
  "maxAttempts": 3,
  "timeoutSeconds": 180,
  "onFailure": "Abort",
  "inputs": {
    "ImageId": "ami-12345678"
  }
}
```

## ImageId

The ID of the image to be deleted.

Type: String

Required: Yes

## Output

None

## aws:deleteStack – Delete an AWS CloudFormation stack

Deletes an AWS CloudFormation stack.

## Input

YAML

```
name: deleteStack
action: aws:deleteStack
maxAttempts: 1
onFailure: Abort
inputs:
  StackName: "{{stackName}}"
```

JSON

```
{
  "name": "deleteStack",
  "action": "aws:deleteStack",
  "maxAttempts": 1,
  "onFailure": "Abort",
  "inputs": {
    "StackName": "{{stackName}}"
  }
}
```

## ClientRequestToken

A unique identifier for this DeleteStack request. Specify this token if you plan to retry requests so that CloudFormation knows that you aren't attempting to delete a stack with the same name. You can retry DeleteStack requests to verify that CloudFormation received them.

Type: String

Length Constraints: Minimum length of 1. Maximum length of 128.

Pattern: [a-zA-Z][-a-zA-Z0-9]\*

Required: No

#### RetainResources.member.N

This input applies only to stacks that are in a `DELETE_FAILED` state. A list of logical resource IDs for the resources you want to retain. During deletion, CloudFormation deletes the stack, but doesn't delete the retained resources.

Retaining resources is useful when you can't delete a resource, such as a non-empty S3 bucket, but you want to delete the stack.

Type: array of strings

Required: No

#### RoleARN

The Amazon Resource Name (ARN) of an AWS Identity and Access Management (IAM) role that CloudFormation assumes to create the stack. CloudFormation uses the role's credentials to make calls on your behalf. CloudFormation always uses this role for all future operations on the stack. As long as users have permission to operate on the stack, CloudFormation uses this role even if the users don't have permission to pass it. Ensure that the role grants the least amount of privileges.

If you don't specify a value, CloudFormation uses the role that was previously associated with the stack. If no role is available, CloudFormation uses a temporary session that is generated from your user credentials.

Type: String

Length Constraints: Minimum length of 20. Maximum length of 2048.

Required: No

#### StackName

The name or the unique stack ID that is associated with the stack.

Type: String

Required: Yes

## Security considerations

Before you can use the `aws:deleteStack` action, you must assign the following policy to the IAM Automation assume role. For more information about the assume role, see [Task 1: Create a service role for Automation](#).

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "sqs:*",
        "cloudformation:DeleteStack",
        "cloudformation:DescribeStacks"
      ],
      "Resource": "*"
    }
  ]
}
```

## `aws:executeAutomation` – Run another automation

Runs a secondary automation by calling a secondary runbook. With this action, you can create runbooks for your most common operations, and reference those runbooks during an automation. This action can simplify your runbooks by removing the need to duplicate steps across similar runbooks.

The secondary automation runs in the context of the user who initiated the primary automation. This means that the secondary automation uses the same AWS Identity and Access Management (IAM) role or user as the user who started the first automation.

### Important

If you specify parameters in a secondary automation that use an assume role (a role that uses the `iam:passRole` policy), then the user or role that initiated the primary automation must have permission to pass the assume role specified in the secondary automation. For

more information about setting up an assume role for Automation, see [Create the service roles for Automation using the console](#).

## Input

### YAML

```
name: Secondary_Automation
action: aws:executeAutomation
maxAttempts: 3
timeoutSeconds: 3600
onFailure: Abort
inputs:
  DocumentName: secondaryAutomation
  RuntimeParameters:
    instanceIds:
      - i-1234567890abcdef0
```

### JSON

```
{
  "name": "Secondary_Automation",
  "action": "aws:executeAutomation",
  "maxAttempts": 3,
  "timeoutSeconds": 3600,
  "onFailure": "Abort",
  "inputs": {
    "DocumentName": "secondaryAutomation",
    "RuntimeParameters": {
      "instanceIds": [
        "i-1234567890abcdef0"
      ]
    }
  }
}
```

## DocumentName

The name of the secondary runbook to run during the step. For runbooks in the same AWS account, specify the runbook name. For runbooks shared from a different AWS account,

specify the Amazon Resource Name (ARN) of the runbook. For information about using shared runbooks, see [Using shared SSM documents](#).

Type: String

Required: Yes

#### DocumentVersion

The version of the secondary runbook to run. If not specified, Automation runs the default runbook version.

Type: String

Required: No

#### MaxConcurrency

The maximum number of targets allowed to run this task in parallel. You can specify a number, such as 10, or a percentage, such as 10%.

Type: String

Required: No

#### MaxErrors

The number of errors that are allowed before the system stops running the automation on additional targets. You can specify either an absolute number of errors, for example 10, or a percentage of the target set, for example 10%. If you specify 3, for example, the system stops running the automation when the fourth error is received. If you specify 0, then the system stops running the automation on additional targets after the first error result is returned. If you run an automation on 50 resources and set `MaxErrors` to 10%, then the system stops running the automation on additional targets when the sixth error is received.

Automations that are already running when the `MaxErrors` threshold is reached are allowed to complete, but some of these automations may fail as well. If you need to ensure that there won't be more failed automations than the specified `MaxErrors`, set `MaxConcurrency` to 1 so the automations proceed one at a time.

Type: String

Required: No

## RuntimeParameters

Required parameters for the secondary runbook. The mapping uses the following format:  
`{"parameter1" : "value1", "parameter2" : "value2" }`

Type: Map

Required: No

## Tags

Optional metadata that you assign to a resource. You can specify a maximum of five tags for an automation.

Type: MapList

Required: No

## TargetLocations

A location is a combination of AWS Regions and/or AWS accounts where you want to run the automation. A minimum number of 1 item must be specified and a maximum number of 100 items can be specified.

Type: MapList

Required: No

## TargetMaps

A list of key-value mappings of document parameters to target resources. Both Targets and TargetMaps can't be specified together.

Type: MapList

Required: No

## TargetParameterName

The name of the parameter used as the target resource for the rate-controlled automation. Required if you specify Targets.

Type: String

Required: No

## Targets

A list of key-value mappings to target resources. Required if you specify `TargetParameterName`.

Type: `MapList`

Required: No

## Output

### Output

The output generated by the secondary automation. You can reference the output by using the following format: *Secondary\_Automation\_Step\_Name*.Output

Type: `StringList`

Here is an example:

```
- name: launchNewWindowsInstance
  action: 'aws:executeAutomation'
  onFailure: Abort
  inputs:
    DocumentName: launchWindowsInstance
    nextStep: getNewInstanceRootVolume
- name: getNewInstanceRootVolume
  action: 'aws:executeAwsApi'
  onFailure: Abort
  inputs:
    Service: ec2
    Api: DescribeVolumes
    Filters:
      - Name: attachment.device
        Values:
          - /dev/sda1
      - Name: attachment.instance-id
        Values:
          - '{{launchNewWindowsInstance.Output}}'
  outputs:
    - Name: rootVolumeId
      Selector: '$.Volumes[0].VolumeId'
      Type: String
```

```
nextStep: snapshotRootVolume
- name: snapshotRootVolume
  action: 'aws:executeAutomation'
  onFailure: Abort
  inputs:
    DocumentName: AWS-CreateSnapshot
    RuntimeParameters:
      VolumeId:
        - '{{getNewInstanceRootVolume.rootVolumeId}}'
    Description:
      - 'Initial root snapshot for {{launchNewWindowsInstance.Output}}'
```

## ExecutionId

The ID of the secondary automation.

Type: String

## Status

The status of the secondary automation.

Type: String

## aws:executeAwsApi – Call and run AWS API operations

Calls and runs AWS API operations. Most API operations are supported, although not all API operations have been tested. Streaming API operations, such as the [GetObject](#) operation, aren't supported. If you're not sure if an API operation you want to use is a streaming operation, review the [Boto3](#) documentation for the service to determine if an API requires streaming inputs or outputs. We regularly update the Boto3 version used by this action. However, following the release of a new Boto3 version it can take up to a few weeks for changes to be reflected in this action. Each `aws:executeAwsApi` action can run up to a maximum duration of 25 seconds. For more examples of how to use this action, see [Additional runbook examples](#).

## Inputs

Inputs are defined by the API operation that you choose.

## YAML

```
action: aws:executeAwsApi
inputs:
```

Service: *The official namespace of the service*  
 Api: *The API operation or method name*  
 API operation inputs or parameters: *A value*  
 outputs: # *These are user-specified outputs*  
 - Name: *The name for a user-specified output key*  
 Selector: *A response object specified by using jsonpath format*  
 Type: *The data type*

## JSON

```

{
  "action": "aws:executeAwsApi",
  "inputs": {
    "Service": "The official namespace of the service",
    "Api": "The API operation or method name",
    "API operation inputs or parameters": "A value"
  },
  "outputs": [ These are user-specified outputs
    {
      "Name": "The name for a user-specified output key",
      "Selector": "A response object specified by using JSONPath format",
      "Type": "The data type"
    }
  ]
}

```

## Service

The AWS service namespace that contains the API operation that you want to run. You can view a list of supported AWS service namespaces in [Available services](#) of the AWS SDK for Python (Boto3). The namespace can be found in the **Client** section. For example, the namespace for Systems Manager is `ssm`. The namespace for Amazon Elastic Compute Cloud (Amazon EC2) is `ec2`.

Type: String

Required: Yes

## Api

The name of the API operation that you want to run. You can view the API operations (also called methods) by choosing a service in the left navigation on the following [Services Reference](#)

page. Choose a method in the **Client** section for the service that you want to invoke. For example, all API operations (methods) for Amazon Relational Database Service (Amazon RDS) are listed on the following page: [Amazon RDS methods](#).

Type: String

Required: Yes

### API operation inputs

One or more API operation inputs. You can view the available inputs (also called parameters) by choosing a service in the left navigation on the following [Services Reference](#) page. Choose a method in the **Client** section for the service that you want to invoke. For example, all methods for Amazon RDS are listed on the following page: [Amazon RDS methods](#). Choose the [describe\\_db\\_instances](#) method and scroll down to see the available parameters, such as **DBInstanceIdentifier**, **Name**, and **Values**.

### YAML

```
inputs:
  Service: The official namespace of the service
  Api: The API operation name
  API input 1: A value
  API Input 2: A value
  API Input 3: A value
```

### JSON

```
"inputs":{
  "Service":"The official namespace of the service",
  "Api":"The API operation name",
  "API input 1":"A value",
  "API Input 2":"A value",
  "API Input 3":"A value"
}
```

Type: Determined by chosen API operation

Required: Yes

## Outputs

Outputs are specified by the user based on the response from the chosen API operation.

### Name

A name for the output.

Type: String

Required: Yes

### Selector

The JSONPath to a specific attribute in the response object. You can view the response objects by choosing a service in the left navigation on the following [Services Reference](#) page. Choose a method in the **Client** section for the service that you want to invoke. For example, all methods for Amazon RDS are listed on the following page: [Amazon RDS methods](#). Choose the [describe\\_db\\_instances](#) method and scroll down to the **Response Structure** section. **DBInstances** is listed as a response object.

Type: Integer, Boolean, String, StringList, StringMap, or MapList

Required: Yes

### Type

The data type for the response element.

Type: Varies

Required: Yes

## **aws:executeScript – Run a script**

### **Important**

Starting December 4, 2024, you won't be able to create or update runbooks that use the `aws:executeScript` action with the Python 3.6, 3.7, or 3.8 runtimes. Starting February 18, 2025, you won't be able to execute runbooks that use the `aws:executeScript` action with the Python 3.6, 3.7, or 3.8 runtimes. We recommend upgrading your runbooks that use the `aws:executeScript` action with Python runtimes, to Python 3.11 before December 4, 2024.

Runs the Python or PowerShell script provided using the specified runtime and handler. Each `aws:executeScript` action can run up to a maximum duration of 600 seconds (10 minutes). You can limit the timeout by specifying the `timeoutSeconds` parameter for an `aws:executeScript` step.

Use return statements in your function to add outputs to your output payload. For examples of defining outputs for your `aws:executeScript` action, see [Example 2: Scripted runbook](#). You can also send the output from `aws:executeScript` actions in your runbooks to the Amazon CloudWatch Logs log group you specify. For more information, see [Logging Automation action output with CloudWatch Logs](#).

If you want to send output from `aws:executeScript` actions to CloudWatch Logs, or if the scripts you specify for `aws:executeScript` actions call AWS API operations, an AWS Identity and Access Management (IAM) service role (or assume role) is always required to run the runbook.

The `aws:executeScript` action contains the following preinstalled PowerShell Core modules:

- Microsoft.PowerShell.Host
- Microsoft.PowerShell.Management
- Microsoft.PowerShell.Security
- Microsoft.PowerShell.Utility
- PackageManagement
- PowerShellGet

To use PowerShell Core modules that aren't preinstalled, your script must install the module with the `-Force` flag, as shown in the following command. The `AWSPowerShell.NetCore` module isn't supported. Replace *ModuleName* with the module you want to install.

```
Install-Module ModuleName -Force
```

To use PowerShell Core cmdlets in your script, we recommend using the `AWS.Tools` modules, as shown in the following commands. Replace each *example resource placeholder* with your own information.

- Amazon S3 cmdlets.

```
Install-Module AWS.Tools.S3 -Force
```

```
Get-S3Bucket -BucketName amzn-s3-demo-bucket
```

- Amazon EC2 cmdlets.

```
Install-Module AWS.Tools.EC2 -Force  
Get-EC2InstanceStatus -InstanceId instance-id
```

- Common, or service independent AWS Tools for Windows PowerShell cmdlets.

```
Install-Module AWS.Tools.Common -Force  
Get-AWSRegion
```

If your script initializes new objects in addition to using PowerShell Core cmdlets, you must also import the module as shown in the following command.

```
Install-Module AWS.Tools.EC2 -Force  
Import-Module AWS.Tools.EC2  
  
$tag = New-Object Amazon.EC2.Model.Tag  
$tag.Key = "Tag"  
$tag.Value = "TagValue"  
  
New-EC2Tag -Resource i-02573cafcfEXAMPLE -Tag $tag
```

For examples of installing and importing AWS.Tools modules, and using PowerShell Core cmdlets in runbooks, see [Visual design experience for Automation runbooks](#).

## Input

Provide the information required to run your script. Replace each *example resource placeholder* with your own information.

### Note

The attachment for a Python script can be a .py file or a .zip file that contains the script. PowerShell scripts must be stored in .zip files.

## YAML

```
action: "aws:executeScript"
inputs:
  Runtime: runtime
  Handler: "functionName"
  InputPayload:
    scriptInput: '{{parameterValue}}'
  Script: |-
    def functionName(events, context):
      ...
  Attachment: "scriptAttachment.zip"
```

## JSON

```
{
  "action": "aws:executeScript",
  "inputs": {
    "Runtime": "runtime",
    "Handler": "functionName",
    "InputPayload": {
      "scriptInput": "{{parameterValue}}"
    },
    "Attachment": "scriptAttachment.zip"
  }
}
```

## Runtime

The runtime language to be used for running the provided script. `aws:executeScript` supports Python 3.7 (`python3.7`), Python 3.8 (`python3.8`), Python 3.9 (`python3.9`) Python 3.10 (`python3.10`), Python 3.11 (`python3.11`) PowerShell Core 6.0 (`dotnetcore2.1`), and PowerShell 7.0 (`dotnetcore3.1`) scripts.

Supported values: **`python3.7` | `python3.8` | `python3.9` | `python3.10` | `python3.11` | `PowerShell Core 6.0` | `PowerShell 7.0`**

Type: String

Required: Yes

## Handler

The name of your function. You must ensure the function defined in the handler has two parameters, events and context. The PowerShell runtime does not support this parameter.

Type: String

Required: Yes (Python) | Not supported (PowerShell)

## InputPayload

A JSON or YAML object that will be passed to the first parameter of the handler. This can be used to pass input data to the script.

Type: String

Required: No

Python

```
description: Tag an instance
schemaVersion: '0.3'
assumeRole: '{{AutomationAssumeRole}}'
parameters:
  AutomationAssumeRole:
    type: String
    description: '(Required) The Amazon Resource Name (ARN) of the IAM role
that allows Automation to perform the actions on your behalf. If no role is
specified, Systems Manager Automation uses your IAM permissions to operate this
runbook.'
  InstanceId:
    type: String
    description: (Required) The ID of the EC2 instance you want to tag.
mainSteps:
- name: tagInstance
  action: 'aws:executeScript'
  inputs:
    Runtime: "python3.8"
    Handler: tagInstance
    InputPayload:
      instanceId: '{{InstanceId}}'
    Script: |-
      def tagInstance(events,context):
        import boto3
```

```

#Initialize client
ec2 = boto3.client('ec2')
instanceId = events['instanceId']
tag = {
    "Key": "Env",
    "Value": "Example"
}
ec2.create_tags(
    Resources=[instanceId],
    Tags=[tag]
)

```

## PowerShell

```

description: Tag an instance
schemaVersion: '0.3'
assumeRole: '{{AutomationAssumeRole}}'
parameters:
  AutomationAssumeRole:
    type: String
    description: '(Required) The Amazon Resource Name (ARN) of the IAM role
that allows Automation to perform the actions on your behalf. If no role is
specified, Systems Manager Automation uses your IAM permissions to operate this
runbook.'
  InstanceId:
    type: String
    description: (Required) The ID of the EC2 instance you want to tag.
mainSteps:
- name: tagInstance
  action: 'aws:executeScript'
  inputs:
    Runtime: PowerShell 7.0
    InputPayload:
      instanceId: '{{InstanceId}}'
    Script: |-
      Install-Module AWS.Tools.EC2 -Force
      Import-Module AWS.Tools.EC2

      $input = $env:InputPayload | ConvertFrom-Json

      $tag = New-Object Amazon.EC2.Model.Tag
      $tag.Key = "Env"
      $tag.Value = "Example"

```

```
New-EC2Tag -Resource $input.instanceId -Tag $tag
```

## Script

An embedded script that you want to run during the automation.

Type: String

Required: No (Python) | Yes (PowerShell)

## Attachment

The name of a standalone script file or .zip file that can be invoked by the action. Specify the same value as the Name of the document attachment file you specify in the Attachments request parameter. For more information, see [Attachments](#) in the *AWS Systems Manager API Reference*. If you're providing a script using an attachment, you must also define a `files` section in the top-level elements of your runbook. For more information, see [Schema version 0.3](#).

To invoke a file for Python, use the `filename.method_name` format in `Handler`.

### Note

The attachment for a Python script can be a .py file or a .zip file that contains the script. PowerShell scripts must be stored in .zip files.

When including Python libraries in your attachment, we recommend adding an empty `__init__.py` file in each module directory. This allows you to import the modules from the library in your attachment within your script content. For example: `from library import module`

Type: String

Required: No

## Output

### Payload

The JSON representation of the object returned by your function. Up to 100KB is returned. If you output a list, a maximum of 100 items is returned.

### **aws:executeStateMachine** – Run an AWS Step Functions state machine

Runs an AWS Step Functions state machine.

### Input

This action supports most parameters for the Step Functions [StartExecution](#) API operation.

### Required AWS Identity and Access Management (IAM) permissions

- `states:DescribeExecution`
- `states:StartExecution`
- `states:StopExecution`

### YAML

```
name: executeTheStateMachine
action: aws:executeStateMachine
inputs:
  stateMachineArn: StateMachine_ARN
  input: '{"parameters":"values"}'
  name: name
```

### JSON

```
{
  "name": "executeTheStateMachine",
  "action": "aws:executeStateMachine",
  "inputs": {
    "stateMachineArn": "StateMachine_ARN",
    "input": "{\"parameters\":\"values\"}",
    "name": "name"
  }
}
```

```
}
```

### stateMachineArn

The Amazon Resource Name (ARN) of the Step Functions state machine.

Type: String

Required: Yes

### name

The name of the execution.

Type: String

Required: No

### input

A string that contains the JSON input data for the execution.

Type: String

Required: No

## Outputs

The following outputs are predefined for this action.

### executionArn

The ARN of the execution.

Type: String

### input

The string that contains the JSON input data of the execution. Length constraints apply to the payload size, and are expressed as bytes in UTF-8 encoding..

Type: String

### name

The name of the execution.

Type: String

output

The JSON output data of the execution. Length constraints apply to the payload size, and are expressed as bytes in UTF-8 encoding.

Type: String

startDate

The date the execution is started.

Type: String

stateMachineArn

The ARN of the executed stated machine.

Type: String

status

The current status of the execution.

Type: String

stopDate

If the execution has already ended, the date the execution stopped.

Type: String

### **aws: invokeWebhook – Invoke an Automation webhook integration**

Invokes the specified Automation webhook integration. For information about creating Automation integrations, see [Creating webhook integrations for Automation](#).

#### **Note**

To use the `aws: invokeWebhook` action, your user or service role must allow the following actions:

- `ssm:GetParameter`
- `kms:Decrypt`

Permission for the AWS Key Management Service (AWS KMS) Decrypt operation is only required if you use a customer managed key to encrypt the parameter for your integration.

## Input

Provide the information for the Automation integration you want to invoke.

### YAML

```
action: "aws:invokeWebhook"
inputs:
  IntegrationName: "exampleIntegration"
  Body: "Request body"
```

### JSON

```
{
  "action": "aws:invokeWebhook",
  "inputs": {
    "IntegrationName": "exampleIntegration",
    "Body": "Request body"
  }
}
```

## IntegrationName

The name of the Automation integration. For example, `exampleIntegration`. The integration you specify must already exist.

Type: String

Required: Yes

## Body

The payload you want to send when your webhook integration is invoked.

Type: String

Required: No

## Output

### Response

The text received from the webhook provider response.

### ResponseCode

The HTTP status code received from the webhook provider response.

## **aws:invokeLambdaFunction – Invoke an AWS Lambda function**

Invokes the specified AWS Lambda function.

### Note

Each `aws:invokeLambdaFunction` action can run up to a maximum duration of 300 seconds (5 minutes). You can limit the timeout by specifying the `timeoutSeconds` parameter for an `aws:invokeLambdaFunction` step.

## Input

This action supports most invoked parameters for the Lambda service. For more information, see [Invoke](#).

### YAML

```
name: invokeMyLambdaFunction
action: aws:invokeLambdaFunction
maxAttempts: 3
timeoutSeconds: 120
onFailure: Abort
inputs:
  FunctionName: MyLambdaFunction
```

### JSON

```
{
  "name": "invokeMyLambdaFunction",
  "action": "aws:invokeLambdaFunction",
  "maxAttempts": 3,
```

```
"timeoutSeconds": 120,  
"onFailure": "Abort",  
"inputs": {  
  "FunctionName": "MyLambdaFunction"  
}  
}
```

### FunctionName

The name of the Lambda function. This function must exist.

Type: String

Required: Yes

### Qualifier

The function version or alias name.

Type: String

Required: No

### InvocationType

The invocation type. The default value is RequestResponse.

Type: String

Valid values: Event | RequestResponse | DryRun

Required: No

### LogType

If the default value is Tail, the invocation type must be RequestResponse. Lambda returns the last 4 KB of log data produced by your Lambda function, base64-encoded.

Type: String

Valid values: None | Tail

Required: No

### ClientContext

The client-specific information.

Required: No

### InputPayload

A YAML or JSON object that is passed to the first parameter of the handler. You can use this input to pass data to the function. This input provides more flexibility and support than the legacy `Payload` input. If you define both `InputPayload` and `Payload` for the action, `InputPayload` takes precedence and the `Payload` value is not used.

Type: `StringMap`

Required: No

### Payload

A JSON string that's passed to the first parameter of the handler. This can be used to pass input data to the function. We recommend using `InputPayload` input for added functionality.

Type: `String`

Required: No

## Output

### StatusCode

The HTTP status code.

### FunctionError

If present, it indicates that an error occurred while executing the function. Error details are included in the response payload.

### LogResult

The base64-encoded logs for the Lambda function invocation. Logs are present only if the invocation type is `RequestResponse`, and the logs were requested.

### Payload

The JSON representation of the object returned by the Lambda function. Payload is present only if the invocation type is `RequestResponse`. Up to 200KB is returned

The following is a portion from the `AWS-PatchInstanceWithRollback` runbook demonstrating how to reference outputs from the `aws:invokeLambdaFunction` action.

## YAML

```

- name: IdentifyRootVolume
  action: aws:invokeLambdaFunction
  inputs:
    FunctionName: "IdentifyRootVolumeLambda-{{automation:EXECUTION_ID}}"
    Payload: '{"InstanceId": "{{InstanceId}}}'
- name: PrePatchSnapshot
  action: aws:executeAutomation
  inputs:
    DocumentName: "AWS-CreateSnapshot"
    RuntimeParameters:
      VolumeId: "{{IdentifyRootVolume.Payload}}"
      Description: "ApplyPatchBaseline restoration case contingency"

```

## JSON

```

{
  "name": "IdentifyRootVolume",
  "action": "aws:invokeLambdaFunction",
  "inputs": {
    "FunctionName": "IdentifyRootVolumeLambda-{{automation:EXECUTION_ID}}",
    "Payload": "{\"InstanceId\": \"{{InstanceId}}}"
  }
},
{
  "name": "PrePatchSnapshot",
  "action": "aws:executeAutomation",
  "inputs": {
    "DocumentName": "AWS-CreateSnapshot",
    "RuntimeParameters": {
      "VolumeId": "{{IdentifyRootVolume.Payload}}",
      "Description": "ApplyPatchBaseline restoration case contingency"
    }
  }
}

```

### aws:loop – Iterate over steps in an automation

This action iterates over a subset of steps in an automation runbook. You can choose a `do while` or `for each` style loop. To construct a `do while` loop, use the `LoopCondition` input parameter. To construct a `for each` loop, use the `Iterators` and `IteratorDataType` input parameters.

When using an `aws:loop` action, only specify either the `Iterators` or `LoopCondition` input parameter. The maximum number of iterations is 100.

The `onCancel` property can only be used for steps defined within a loop. The `onCancel` property isn't supported for the `aws:loop` action. The `onFailure` property can be used for an `aws:loop` action, however it will only be used if an unexpected error occurs causing the step to fail. If you define `onFailure` properties for the steps within a loop, the `aws:loop` action inherits those properties and reacts accordingly when a failure occurs.

## Examples

The following are examples of how to construct the different types of loop actions.

### do while

```
name: RepeatMyLambdaFunctionUntilOutputIsReturned
action: aws:loop
inputs:
  Steps:
    - name: invokeMyLambda
      action: aws:invokeLambdaFunction
      inputs:
        FunctionName: LambdaFunctionName
      outputs:
        - Name: ShouldRetry
          Selector: $.Retry
          Type: Boolean
  LoopCondition:
    Variable: "{{ invokeMyLambda.ShouldRetry }}"
    BooleanEquals: true
  MaxIterations: 3
```

### for each

```
name: stopAllInstancesWithWaitTime
action: aws:loop
inputs:
  Iterators: "{{ DescribeInstancesStep.InstanceIds }}"
  IteratorDataType: "String"
  Steps:
    - name: stopOneInstance
      action: aws:changeInstanceState
```

```
inputs:
  InstanceIds:
    - "{{stopAllInstancesWithWaitTime.CurrentIteratorValue}}"
  CheckStateOnly: false
  DesiredState: stopped
- name: wait10Seconds
  action: aws:sleep
  inputs:
    Duration: PT10S
```

## Input

The input is as follows.

### Iterators

The list of items for the steps to iterate over. The maximum number of iterators is 100.

Type: StringList

Required: No

### IteratorDataType

An optional parameter to specify the data type of the `Iterators`. A value for this parameter can be provided along with the `Iterators` input parameter. If you don't specify a value for this parameter and `Iterators`, then you must specify a value for the `LoopCondition` parameter.

Type: String

Valid values: Boolean | Integer | String | StringMap

Default: String

Required: No

### LoopCondition

Consists of a `Variable` and an operator condition to evaluate. If you don't specify a value for this parameter, then you must specify values for the `Iterators` and `IteratorDataType` parameters. You can use complex operator evaluations by using a combination of `And`, `Not`, and `Or` operators. The condition is evaluated after the steps in the loop complete. If the condition is

`true` and the `MaxIterations` value has not been reached, the steps in the loop run again. The operator conditions are as follows:

### String operations

- `StringEquals`
- `EqualsIgnoreCase`
- `StartsWith`
- `EndsWith`
- `Contains`

### Numeric operations

- `NumericEquals`
- `NumericGreater`
- `NumericLesser`
- `NumericGreaterOrEquals`
- `NumericLesser`
- `NumericLesserOrEquals`

### Boolean operation

- `BooleanEquals`

Type: `StringMap`

Required: No

### MaxIterations

The maximum number of times the steps in the loop run. Once the value specified for this input is reached, the loop stops running even if the `LoopCondition` is still `true` or if there are objects remaining in the `Iterators` parameter.

Type: `Integer`

Valid values: 1 - 100

Required: No

## Steps

The list of steps to run in the loop. These function like a nested runbook. Within these steps you can access the current iterator value for a `for` each loop using the syntax `{{loopStepName.CurrentIteratorValue}}`. You can also access an integer value of the current iteration for both loop types using the syntax `{{loopStepName.CurrentIteration}}`.

Type: List of steps

Required: Yes

## Output

### CurrentIteration

The current loop iteration as an integer. Iteration values start at 1.

Type: Integer

### CurrentIteratorValue

The value of the current iterator as a string. This output is only present in `for` each loops.

Type: String

## **aws:pause – Pause an automation**

This action pauses the automation. Once paused, the automation status is *Waiting*. To continue the automation, use the [SendAutomationSignal](#) API operation with the Resume signal type. We recommend using the `aws:sleep` or `aws:approve` action for more granular control of your workflows.

## Input

The input is as follows.

## YAML

```
name: pauseThis
action: aws:pause
```

```
inputs: {}
```

## JSON

```
{
  "name": "pauseThis",
  "action": "aws:pause",
  "inputs": {}
}
```

## Output

None

### **aws:runCommand – Run a command on a managed instance**

Runs the specified commands.

#### Note

Automation only supports *output* of one AWS Systems Manager Run Command action. A runbook can include multiple Run Command actions, but output is supported for only one action at a time.

## Input

This action supports most send command parameters. For more information, see [SendCommand](#).

## YAML

```
- name: checkMembership
  action: 'aws:runCommand'
  inputs:
    DocumentName: AWS-RunPowerShellScript
    InstanceIds:
      - '{{InstanceIds}}'
    Parameters:
      commands:
```

```
- (Get-WmiObject -Class Win32_ComputerSystem).PartOfDomain
```

## JSON

```
{
  "name": "checkMembership",
  "action": "aws:runCommand",
  "inputs": {
    "DocumentName": "AWS-RunPowerShellScript",
    "InstanceIds": [
      "{{InstanceIds}}"
    ],
    "Parameters": {
      "commands": [
        "(Get-WmiObject -Class Win32_ComputerSystem).PartOfDomain"
      ]
    }
  }
}
```

### DocumentName

If the Command type document is owned by you or AWS, specify the name of the document. If you're using a document shared with you by a different AWS account, specify the Amazon Resource Name (ARN) of the document. For more information about using shared documents, see [Using shared SSM documents](#).

Type: String

Required: Yes

### InstanceIds

The instance IDs where you want the command to run. You can specify a maximum of 50 IDs.

You can also use the pseudo parameter `{{RESOURCE_ID}}` in place of instance IDs to run the command on all instances in the target group. For more information about pseudo parameters, see [Using pseudo parameters when registering maintenance window tasks](#).

Another alternative is to send commands to a fleet of instances by using the `Targets` parameter. The `Targets` parameter accepts Amazon Elastic Compute Cloud (Amazon EC2) tags. For more information about how to use the `Targets` parameter, see [Run commands at scale](#).

## Type: StringList

Required: No (If you don't specify InstanceIds or use the `{{RESOURCE_ID}}` pseudo parameter, then you must specify the Targets parameter.)

## Targets

An array of search criteria that targets instances by using a Key,Value combination that you specify. Targets is required if you don't provide one or more instance IDs in the call. For more information about how to use the Targets parameter, see [Run commands at scale](#).

Type: MapList (The schema of the map in the list must match the object.) For information, see [Target](#) in the *AWS Systems Manager API Reference*.

Required: No (If you don't specify Targets, then you must specify InstanceIds or use the `{{RESOURCE_ID}}` pseudo parameter.)

Following is an example.

## YAML

```
- name: checkMembership
  action: aws:runCommand
  inputs:
    DocumentName: AWS-RunPowerShellScript
    Targets:
      - Key: tag:Stage
        Values:
          - Gamma
          - Beta
      - Key: tag-key
        Values:
          - Suite
    Parameters:
      commands:
        - (Get-WmiObject -Class Win32_ComputerSystem).PartOfDomain
```

## JSON

```
{
  "name": "checkMembership",
  "action": "aws:runCommand",
  "inputs": {
```

```
"DocumentName": "AWS-RunPowerShellScript",
"Targets": [
  {
    "Key": "tag:Stage",
    "Values": [
      "Gamma", "Beta"
    ]
  },
  {
    "Key": "tag:Application",
    "Values": [
      "Suite"
    ]
  }
],
"Parameters": {
  "commands": [
    "(Get-WmiObject -Class Win32_ComputerSystem).PartOfDomain"
  ]
}
}
```

## Parameters

The required and optional parameters specified in the document.

Type: Map

Required: No

## CloudWatchOutputConfig

Configuration options for sending command output to Amazon CloudWatch Logs. For more information about sending command output to CloudWatch Logs, see [Configuring Amazon CloudWatch Logs for Run Command](#).

Type: StringMap (The schema of the map must match the object. For more information, see [CloudWatchOutputConfig](#) in the *AWS Systems Manager API Reference*).

Required: No

Following is an example.

## YAML

```
- name: checkMembership
  action: aws:runCommand
  inputs:
    DocumentName: AWS-RunPowerShellScript
    InstanceIds:
      - "{{InstanceIds}}"
    Parameters:
      commands:
        - "(Get-WmiObject -Class Win32_ComputerSystem).PartOfDomain"
  CloudWatchOutputConfig:
    CloudWatchLogGroupName: CloudWatchGroupForSSMAutomationService
    CloudWatchOutputEnabled: true
```

## JSON

```
{
  "name": "checkMembership",
  "action": "aws:runCommand",
  "inputs": {
    "DocumentName": "AWS-RunPowerShellScript",
    "InstanceIds": [
      "{{InstanceIds}}"
    ],
    "Parameters": {
      "commands": [
        "(Get-WmiObject -Class Win32_ComputerSystem).PartOfDomain"
      ]
    }
  },
  "CloudWatchOutputConfig" : {
    "CloudWatchLogGroupName":
"CloudWatchGroupForSSMAutomationService",
    "CloudWatchOutputEnabled": true
  }
}
```

## Comment

User-defined information about the command.

Type: String

Required: No

### DocumentHash

The hash for the document.

Type: String

Required: No

### DocumentHashType

The type of the hash.

Type: String

Valid values: Sha256 | Sha1

Required: No

### NotificationConfig

The configurations for sending notifications.

Required: No

### OutputS3BucketName

The name of the S3 bucket for command output responses.

Type: String

Required: No

### OutputS3KeyPrefix

The prefix.

Type: String

Required: No

### ServiceRoleArn

The ARN of the AWS Identity and Access Management (IAM) role.

Type: String

Required: No

### TimeoutSeconds

The amount of time in seconds to wait for a command to deliver to the AWS Systems Manager SSM Agent on an instance. If the command isn't received by the SSM Agent on the instance before the value specified is reached, then the status of the command changes to `DeliveryTimedOut`.

Type: Integer

Required: No

Valid values: 30-2592000

## Output

### CommandId

The ID of the command.

### Status

The status of the command.

### ResponseCode

The response code of the command. If the document you run has more than 1 step, a value isn't returned for this output.

### Output

The output of the command. If you target a tag or multiple instances with your command, no output value is returned. You can use the `GetCommandInvocation` and `ListCommandInvocations` API operations to retrieve output for individual instances.

## **aws:runInstances – Launch an Amazon EC2 instance**

Launches a new Amazon Elastic Compute Cloud (Amazon EC2) instance.

## Input

The action supports most API parameters. For more information, see the [RunInstances](#) API documentation.

## YAML

```
name: launchInstance
action: aws:runInstances
maxAttempts: 3
timeoutSeconds: 1200
onFailure: Abort
inputs:
  ImageId: ami-12345678
  InstanceType: t2.micro
  MinInstanceCount: 1
  MaxInstanceCount: 1
  IamInstanceProfileName: myRunCmdRole
  TagSpecifications:
  - ResourceType: instance
    Tags:
    - Key: LaunchedBy
      Value: SSMAutomation
    - Key: Category
      Value: HighAvailabilityFleetHost
```

## JSON

```
{
  "name": "launchInstance",
  "action": "aws:runInstances",
  "maxAttempts": 3,
  "timeoutSeconds": 1200,
  "onFailure": "Abort",
  "inputs": {
    "ImageId": "ami-12345678",
    "InstanceType": "t2.micro",
    "MinInstanceCount": 1,
    "MaxInstanceCount": 1,
    "IamInstanceProfileName": "myRunCmdRole",
    "TagSpecifications": [
      {
        "ResourceType": "instance",
        "Tags": [
          {
            "Key": "LaunchedBy",
            "Value": "SSMAutomation"
          }
        ]
      }
    ]
  }
}
```

```
    {
      "Key": "Category",
      "Value": "HighAvailabilityFleetHost"
    }
  ]
}
```

### AdditionalInfo

Reserved.

Type: String

Required: No

### BlockDeviceMappings

The block devices for the instance.

Type: MapList

Required: No

### ClientToken

The identifier to ensure idempotency of the request.

Type: String

Required: No

### DisableApiTermination

Turns on or turns off instance API termination.

Type: Boolean

Required: No

### EbsOptimized

Turns on or turns off Amazon Elastic Block Store (Amazon EBS) optimization.

Type: Boolean

Required: No

#### iamInstanceProfileArn

The Amazon Resource Name (ARN) of the AWS Identity and Access Management (IAM) instance profile for the instance.

Type: String

Required: No

#### iamInstanceProfileName

The name of the IAM instance profile for the instance.

Type: String

Required: No

#### ImageId

The ID of the Amazon Machine Image (AMI).

Type: String

Required: Yes

#### InstanceInitiatedShutdownBehavior

Indicates whether the instance stops or terminates on system shutdown.

Type: String

Required: No

#### InstanceType

The instance type.

 **Note**

If an instance type value isn't provided, the m1.small instance type is used.

Type: String

Required: No

### KernelId

The ID of the kernel.

Type: String

Required: No

### KeyName

The name of the key pair.

Type: String

Required: No

### MaxInstanceCount

The maximum number of instances to be launched.

Type: String

Required: No

### MetadataOptions

The metadata options for the instance. For more information, see [InstanceMetadataOptionsRequest](#).

Type: StringMap

Required: No

### MinInstanceCount

The minimum number of instances to be launched.

Type: String

Required: No

### Monitoring

Turns on or turns off detailed monitoring.

Type: Boolean

Required: No

### NetworkInterfaces

The network interfaces.

Type: MapList

Required: No

### Placement

The placement for the instance.

Type: StringMap

Required: No

### PrivateIpAddress

The primary IPv4 address.

Type: String

Required: No

### RamdiskId

The ID of the RAM disk.

Type: String

Required: No

### SecurityGroupIds

The IDs of the security groups for the instance.

Type: StringList

Required: No

### SecurityGroups

The names of the security groups for the instance.

Type: StringList

Required: No

## SubnetId

The subnet ID.

Type: String

Required: No

## TagSpecifications

The tags to apply to the resources during launch. You can only tag instances and volumes at launch. The specified tags are applied to all instances or volumes that are created during launch. To tag an instance after it has been launched, use the [aws:createTags – Create tags for AWS resources](#) action.

Type: MapList (For more information, see [TagSpecification](#).)

Required: No

## UserData

A script provided as a string literal value. If a literal value is entered, then it must be Base64-encoded.

Type: String

Required: No

## Output

### InstanceIds

The IDs of the instances.

### InstanceStates

The current state of the instance.

## aws:sleep – Delay an automation

Delays an automation for a specified amount of time. This action uses the International Organization for Standardization (ISO) 8601 date and time format. For more information about this date and time format, see [ISO 8601](#).

## Input

You can delay an automation for a specified duration.

### YAML

```
name: sleep
action: aws:sleep
inputs:
  Duration: PT10M
```

### JSON

```
{
  "name": "sleep",
  "action": "aws:sleep",
  "inputs": {
    "Duration": "PT10M"
  }
}
```

You can also delay an automation until a specified date and time. If the specified date and time has passed, the action proceeds immediately.

### YAML

```
name: sleep
action: aws:sleep
inputs:
  Timestamp: '2020-01-01T01:00:00Z'
```

### JSON

```
{
  "name": "sleep",
  "action": "aws:sleep",
  "inputs": {
    "Timestamp": "2020-01-01T01:00:00Z"
  }
}
```

**Note**

Automation supports a maximum delay of 604799 seconds (7 days).

**Duration**

An ISO 8601 duration. You can't specify a negative duration.

Type: String

Required: No

**Timestamp**

An ISO 8601 timestamp. If you don't specify a value for this parameter, then you must specify a value for the `Duration` parameter.

Type: String

Required: No

**Output**

None

**aws:updateVariable – Updates a value for a runbook variable**

This action updates a value for a runbook variable. The data type of the value must match the data type of the variable you want to update. Data type conversions aren't supported. The `onCancel` property isn't supported for the `aws:updateVariable` action.

**Input**

The input is as follows.

**YAML**

```
name: updateStringList
```

```
action: aws:updateVariable
inputs:
  Name: variable:variable name
  Value:
    - "1"
    - "2"
```

## JSON

```
{
  "name": "updateStringList",
  "action": "aws:updateVariable",
  "inputs": {
    "Name": "variable:variable name",
    "Value": ["1","2"]
  }
}
```

## Name

The name of the variable whose value you want to update. You must use the format `variable:variable name`

Type: String

Required: Yes

## Value

The new value to assign to the variable. The value must match the data type of the variable. Data type conversions aren't supported.

Type: Boolean | Integer | MapList | String | StringList | StringMap

Required: Yes

Constraints:

- MapList can contain a maximum number of 200 items.
- Key lengths can be a minimum length of 1 and a maximum length of 50.
- StringList can be a minimum number of 0 items and a maximum number of 50 items.

- String lengths can be a minimum length of 1 and a maximum length of 512.

## Output

None

### **aws:waitForAwsResourceProperty** – Wait on an AWS resource property

The `aws:waitForAwsResourceProperty` action allows your automation to wait for a specific resource state or event state before continuing the automation. For more examples of how to use this action, see [Additional runbook examples](#).

#### Note

The default timeout value for this action is 3600 seconds (one hour). You can limit or extend the timeout by specifying the `timeoutSeconds` parameter for an `aws:waitForAwsResourceProperty` step. For more information and examples of how to use this action, see [Handling timeouts in runbooks](#).

## Input

Inputs are defined by the API operation that you choose.

### YAML

```
action: aws:waitForAwsResourceProperty
inputs:
  Service: The official namespace of the service
  Api: The API operation or method name
  API operation inputs or parameters: A value
  PropertySelector: Response object
  DesiredValues:
    - Desired property value
```

### JSON

```
{
```

```
"action": "aws:waitForAwsResourceProperty",
"inputs": {
  "Service": "The official namespace of the service",
  "Api": "The API operation or method name",
  "API operation inputs or parameters": "A value",
  "PropertySelector": "Response object",
  "DesiredValues": [
    "Desired property value"
  ]
}
```

## Service

The AWS service namespace that contains the API operation that you want to run. For example, the namespace for AWS Systems Manager is `ssm`. The namespace for Amazon Elastic Compute Cloud (Amazon EC2) is `ec2`. You can view a list of supported AWS service namespaces in the [Available Services](#) section of the *AWS CLI Command Reference*.

Type: String

Required: Yes

## Api

The name of the API operation that you want to run. You can view the API operations (also called methods) by choosing a service in the left navigation on the following [Services Reference](#) page. Choose a method in the **Client** section for the service that you want to invoke. For example, all API operations (methods) for Amazon Relational Database Service (Amazon RDS) are listed on the following page: [Amazon RDS methods](#).

Type: String

Required: Yes

## API operation inputs

One or more API operation inputs. You can view the available inputs (also called parameters) by choosing a service in the left navigation on the following [Services Reference](#) page. Choose a method in the **Client** section for the service that you want to invoke. For example, all methods for Amazon RDS are listed on the following page: [Amazon RDS methods](#). Choose

the [describe\\_db\\_instances](#) method and scroll down to see the available parameters, such as **DBInstanceIdentifier**, **Name**, and **Values**.

#### YAML

```
inputs:
  Service: The official namespace of the service
  Api: The API operation name
  API input 1: A value
  API Input 2: A value
  API Input 3: A value
```

#### JSON

```
"inputs":{
  "Service":"The official namespace of the service",
  "Api":"The API operation name",
  "API input 1":"A value",
  "API Input 2":"A value",
  "API Input 3":"A value"
}
```

Type: Determined by chosen API operation

Required: Yes

#### PropertySelector

The JSONPath to a specific attribute in the response object. You can view the response objects by choosing a service in the left navigation on the following [Services Reference](#) page. Choose a method in the **Client** section for the service that you want to invoke. For example, all methods for Amazon RDS are listed on the following page: [Amazon RDS methods](#). Choose the [describe\\_db\\_instances](#) method and scroll down to the **Response Structure** section. **DBInstances** is listed as a response object.

Type: String

Required: Yes

#### DesiredValues

The expected status or state on which to continue the automation.

Type: MapList, StringList

Required: Yes

## Automation system variables

AWS Systems Manager Automation runbooks use the following variables. For an example of how these variables are used, view the JSON source of the `AWS-UpdateWindowsAmi` runbook.

### To view the JSON source of the `AWS-UpdateWindowsAmi` runbook

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Documents**.
3. In the document list, use either the Search bar or the numbers to the right of the Search bar to choose the runbook **AWS-UpdateWindowsAmi**.
4. Choose the **Content** tab.

## System variables

Automation runbooks support the following system variables.

| Variable                          | Details   |
|-----------------------------------|---|
| <code>global:ACCOUNT_ID</code>    | The AWS account ID of the user or role in which Automation runs.  |
| <code>global:DATE</code>          | The date (at run time) in the format <code>yyyy-MM-dd</code> .  |
| <code>global:DATE_TIME</code>     | The date and time (at run time) in the format <code>yyyy-MM-dd_HH.mm.ss</code> .  |
| <code>global:AWS_PARTITION</code> | The partition that the resource is in. For standard AWS Regions, the partition is <code>aws</code> . For resources in other partitions, the partition is <code>aws-<i>partitionname</i></code> . For example, the partition for resources in the AWS GovCloud (US-West) Region is <code>aws-us-gov</code> . |

| Variable                   | Details  |
|----------------------------|--|
| <code>global:REGION</code> | The Region that the runbook is run in. For example, <code>us-east-2</code> . |

## Automation variables

Automation runbooks support the following automation variables.

| Variable                             | Details   |
|--------------------------------------|---|
| <code>automation:EXECUTION_ID</code> | The unique identifier assigned to the current automation. For example, <code>1a2b3c-1a2b3c-1a2b3c-1a2b3c1a2b3c1a2b3c</code> . |

## Topics

- [Terminology](#)
- [Supported scenarios](#)
- [Unsupported scenarios](#)

## Terminology

The following terms describe how variables and parameters are resolved.

| Term              | Definition   | Example  |
|-------------------|--|--|
| Constant ARN      | A valid Amazon Resource Name (ARN) without variables .   | <code>arn:aws:iam::123456789012:role/roleName</code>                     |
| Runbook parameter | A parameter defined at the runbook level (for example, <code>instanceId</code> ). The parameter is used in a basic string replace. Its value | <pre>{   "description":   "Create Image Demo",   "version": "0.3",</pre> |

| Term | Definition                           | Example   |
|------|--------------------------------------|---|
|      | is supplied at Start Execution time. | <pre>"assumeRole":<br/>  "<i>Your_Automation_Assume_Role_ARN</i> ",<br/>  "parameters":{<br/>    "instanceId": {<br/>      "type":<br/>        "String",<br/>      "description":<br/>        "Instance to create<br/>        image from"<br/>    }<br/>  }<br/>}</pre> |

| Term            | Definition   | Example   |
|-----------------|--|---|
| System variable | A general variable substituted into the runbook when any part of the runbook is evaluated. | <pre>"activities": [<br/>  {<br/>    "id": "copyImage",<br/>    "activityType":<br/>    "AWS-CopyImage",<br/>    "maxAttempts": 1,<br/>    "onFailure":<br/>    "Continue",<br/>    "inputs": {<br/>      "imageName":<br/>      "{{imageName}}",<br/>      "sourceImageId": "{{sourceImageId}}",<br/>      "sourceRegion": "{{sourceRegion}}",<br/>      "Encrypted":<br/>      true,<br/>      "ImageDescription": "Test<br/>CopyImage Description<br/>created on <b>{{global:<br/>DATE}}</b> "<br/>    }<br/>  }<br/>]</pre> |

| Term                | Definition  | Example  |
|---------------------|---|--|
| Automation variable | A variable relating to the automation substituted into the runbook when any part of the runbook is evaluated. | <pre data-bbox="1073 239 1507 1472"> {   "name": "runFixed Cmds",   "action": "aws:runC ommand",   "maxAttempts": 1,   "onFailure": "Continue",   "inputs": {     "DocumentName": "AWS-RunPowerShell Script",     "InstanceIds": [       "{{Launch Instance.InstanceI ds}}"     ],     "Parameters": {       "commands": [         "dir",         "date",         "{{outpu tFormat}}"         -f "left","r ight","{{global:DA TE}}"," {{automat ion:EXECUTION_ID}}  "       ]     }   } } </pre> |

| Term                      | Definition   | Example  |
|---------------------------|--|--|
| Systems Manager Parameter | A variable defined within AWS Systems Manager Parameter Store. It can't be directly referenced in step input. Permissions might be required to access the parameter. | <pre> description: Launch new   Windows test instance schemaVersion: '0.3' assumeRole: '{{AutomationAssumeRole}}' parameters:   AutomationAssumeRole:     type: String     default: ''     description: &gt;-       (Required) The       ARN of the role that       allows Automation to       perform the       actions on your       behalf. If no role is       specified, Systems       Manager       Automation uses       your IAM permissions       to run this runbook.   LatestAmi:     type: String     default: &gt;-       {{ssm:/aws/ service/ami-wind ows-latest/Windows _Server-2016-English- Full-Base}}     description: The     latest Windows Server     2016 AMI queried from     the public parameter. mainSteps:   - name: launchIns tance     action: 'aws:runI nstances'     maxAttempts: 3 </pre> |

| Term | Definition | Example  |
|------|------------|--|
|      |            | <pre> timeoutSeconds:   1200   onFailure: Abort   inputs:     ImageId: '{{Latest Ami}}' ... </pre> |

## Supported scenarios

| Scenario  | Comments  | Example   |
|---|---|---|
| Constant ARN assumeRole at creation.                                      | An authorization check is performed to verify that the calling user is permitted to pass the given assumeRole . | <pre> {   "description":     "Test all Automation     resolvable parameter     s",   "schemaVersion":     "0.3",   "assumeRo   le": "<b>arn:aws:   iam::123456789012:   role/roleName</b>" ,   "parameters": {     ...   } } </pre> |
| Runbook parameter supplied for AssumeRole when the automation is started. | Must be defined in the parameter list of the runbook.   | <pre> {   "description":     "Test all Automation     resolvable parameter     s",   "schemaVersion":     "0.3",   "assumeRo   le": "<b>{{dynamicARN}}</b>" ,   "parameters": {     ...   } } </pre>                                |

| Scenario                                       | Comments   | Example   |
|--|--|---|
| Value supplied for runbook parameter at start. | Customer supplies the value to use for a parameter. Any inputs supplied at start time need to be defined in the parameter list of the runbook. | <pre data-bbox="1068 226 1510 739">... "parameters": {   "amiId": {     "type": "String",     "default":       "ami-12345678 ",     "description":       "list of commands to       run as part of first       step"   },   ... }</pre> <p data-bbox="1068 781 1510 961">Inputs to Start Automation Execution include :<br/>{"amiId" : ["ami-12345678 " ] }</p> |

| Scenario  | Comments  | Example  |
|---|---|--|
| <p>Systems Manager Parameter referenced within runbook content.</p> | <p>The variable exists within the customer's account, or is a publicly accessible parameter, and the <code>AssumeRole</code> for the runbook has access to the variable. A check is performed at create time to confirm the <code>AssumeRole</code> has access. The parameter can't be directly referenced in step input.</p> | <pre> ... parameters:   LatestAmi:     type: String     default: &gt;-       {{ssm:/aws/ service/ami-wind ows-latest/Windows _Server-2016-English- Full-Base}}     description: The latest Windows Server 2016 AMI queried from the public parameter. mainSteps:   - name: launchIns tance     action: 'aws:runI nstances'     maxAttempts: 3     timeoutSeconds: 1200     onFailure: Abort     inputs:       ImageId: '{{Latest Ami}}' ... </pre> |

| Scenario  | Comments  | Example   |
|---|---|---|
| System variable referenced within step definition | A system variable is substituted into the runbook when the automation is started. The value injected into the runbook is relative to when the substitution occurs. That is, the value of a time variable injected at step 1 is different from the value injected at step 3 because of the time it takes to run the steps between. System variables don't need to be set in the parameter list of the runbook. | <pre>...   "mainSteps": [     {       "name": "RunSomeC ommands",       "action": "aws:runCommand",       "maxAttempts": 1,       "onFailure": "Continue",       "inputs": {         "DocumentName": "AWS:RunPowerShell",         "InstanceIds": ["{{LaunchInstance .InstanceIds}}"],         "Parameters": {           "commands " : [               "echo {The time is now {{global:DATE_TIME }}}"             ]           }         }       }, ...</pre> |

| Scenario   | Comments   | Example   |
|--|--|---|
| Automation variable referenced within step definition. | Automation variables don't need to be set in the parameter list of the runbook. The only supported Automation variable is <b>automation:EXECUTION_ID</b> . | <pre>... "mainSteps": [   {     "name": "invokeLambdaFunction",     "action":       "aws:invokeLambdaFunction",     "maxAttempts": 1,     "onFailure":       "Continue",     "inputs": {       "FunctionName":         "Hello-World-LambdaFunction",        "Payload" :         "{ \"executionId\" :           \"{{automation:EXECUTION_ID}}\" }"     }   } ] ...</pre> |

| Scenario   | Comments   | Example   |
|--|--|---|
| <p>Refer to output from previous step within next step definition.</p> | <p>This is parameter redirection. The output of a previous step is referenced using the syntax <code>{{stepName.OutputName}}</code>. This syntax can't be used by the customer for runbook parameters. This is resolved when the referring step runs. The parameter isn't listed in the parameters of the runbook.</p> | <pre> ... "mainSteps": [   {     "name": "LaunchInstance",     "action":       "aws:runInstances",     "maxAttempts": 1,     "onFailure":       "Continue",     "inputs": {       "ImageId":         "{{amiId}}",       "MinInstanceCount": 1,       "MaxInstanceCount": 2     }   },   {     "name": "changeState",     "action":       "aws:changeInstanceState",     "maxAttempts": 1,     "onFailure":       "Continue",     "inputs": {       "InstanceIds":         ["{{LaunchInstance.InstanceIds}}"],       "DesiredState":         "terminated"     }   } ] ... </pre> |

## Unsupported scenarios

| Scenario   | Comment   | Example   |
|--|---|---|
| Systems Manager Parameter supplied for <code>assumeRole</code> at create | Not supported.  | <pre> ...  {   "description":     "Test all Automation     resolvable parameter s",   "schemaVersion":     "0.3",   "assumeRole":     "{{ssm:administrato rRoleARN}} ",   "parameters": { ... </pre>  |
| Systems Manager Parameter directly referenced in step input.             | Returns <code>InvalidDocumentContent</code> exception at create time. | <pre> ... mainSteps:   - name: launchIns tance     action: 'aws:runI nstances'     maxAttempts: 3     timeoutSeconds: 1200     onFailure: Abort     inputs:       ImageId: '{{ssm:/ aws/service/ami-win dows-latest/Window s_Server-2016-Engl ish-Full-Base}}' ... </pre> |

| Scenario                 | Comment  | Example  |
|--------------------------|--|--|
| Variable step definition | The definition of a step in the runbook is constructed by variables. | <pre>...  "mainSteps": [   {     "name": "LaunchIn stance",     "action": "aws:runInstances",     "{{attempt Model}} ": 1,     "onFailure": "Continue",     "inputs": {       "ImageId": "ami-12345678 ",       "MinInsta nceCount": 1,       "MaxInsta nceCount": 2     }   } }  ...  User supplies input : { "attemptModel" : "minAttempts " }</pre> |

| Scenario                             | Comment   | Example   |
|--------------------------------------|---|---|
| Cross referencing runbook parameters | The user supplies an input parameter at start time, which is a reference to another parameter in the runbook. | <pre>... "parameters": {   "amiId": {     "type": "String",     "default":       "ami-7f2e6015 ",     "description":       "list of commands to       run as part of first       step"   },   "alternateAmiId": {     "type": "String",     "description":       "The alternate AMI       to try if this first       fails".      "default" : "{{amiId}}   }" }, ... </pre> |

| Scenario              | Comment   | Example  |
|-----------------------|---|--|
| Multi-level expansion | The runbook defines a variable that evaluates to the name of a variable. This sits within the variable delimiters (that is <code>{{}}</code> ) and is expanded to the value of that variable/parameter. | <pre> ... "parameters": {   "firstParameter ": {     "type": "String",     "default": "param2",     "description": "The parameter to reference"   },   "secondParameter ": {   "type": "String",   "default" : "echo {Hello world}",   "description": "What to run" } }, "mainSteps": [{   "name": "runFixed Cmds",   "action": "aws:runCommand",   "maxAttempts": 1,   "onFailure": "Continue",   "inputs": {     "DocumentName": "AWS-RunPowerShell Script",  "InstanceIds" : "{{LaunchInstance. InstanceIds}}",     "Parameters": {       "commands ": [ "{{ {{firstPa rameter}} }}" ] } } </pre> |

| Scenario | Comment | Example   |
|----------|---------|---|
|          |         | <p>...</p> <p>Note: The customer intention here would be to run a command of "echo {Hello world}"</p> |

| Scenario   | Comment   | Example  |
|--|---|--|
| Referencing output from a runbook step that is a different variable type | The user references the output from a preceding runbook step within a subsequent step. The output is a variable type that doesn't meet the requirements of the action in the subsequent step. | <pre> ... mainSteps: - name: getImageId   action: aws:executeAwsApi   inputs:     Service: ec2     Api: DescribeImages     Filters:       - Name: "name"         Values:           - "{{ImageName}}"   outputs:     - Name: ImageIdList       Selector: "\$.Images"     Type: "StringList" - name: copyMyImages   action: aws:copyImage   maxAttempts: 3   onFailure: Abort   inputs:     SourceImageId:       {{getImageId.ImageIdList}}     SourceRegion: ap-northeast-2     ImageName:       Encrypted Copies of LAMP base AMI in ap-northeast-2     Encrypted: true ... Note: You must provide the type required by the Automation action. In this case, aws:copyImage requires a "String" type variable but the preceding step </pre> |

| Scenario | Comment | Example                               |
|----------|---------|---------------------------------------|
|          |         | outputs a "StringList" type variable. |

## Creating your own runbooks

An Automation runbook defines the *actions* that Systems Manager performs on your managed instances and other AWS resources when an automation runs. Automation is a capability of AWS Systems Manager. A runbook contains one or more steps that run in sequential order. Each step is built around a single action. Output from one step can be used as input in a later step.

The process of running these actions and their steps is called the *automation*.

Action types supported for runbooks let you automate a wide variety of operations in your AWS environment. For example, using the `executeScript` action type, you can embed a python or PowerShell script directly in your runbook. (When you create a custom runbook, you can add your script inline, or attach it from an S3 bucket or from your local machine.) You can automate management of your AWS CloudFormation resources by using the `createStack` and `deleteStack` action types. In addition, using the `executeAwsApi` action type, a step can run *any* API operation in any AWS service, including creating or deleting AWS resources, starting other processes, initiating notifications, and many more.

For a list of all 20 supported action types for Automation, see [Systems Manager Automation actions reference](#).

AWS Systems Manager Automation provides several runbooks with pre-defined steps that you can use to perform common tasks like restarting one or more Amazon Elastic Compute Cloud (Amazon EC2) instances or creating an Amazon Machine Image (AMI). You can also create your own runbooks and share them with other AWS accounts, or make them public for all Automation users.

Runbooks are written using YAML or JSON. Using the **Document Builder** in the Systems Manager Automation console, however, you can create a runbook without having to author in native JSON or YAML.

**⚠ Important**

If you run an automation workflow that invokes other services by using an AWS Identity and Access Management (IAM) service role, be aware that the service role must be configured with permission to invoke those services. This requirement applies to all AWS Automation runbooks (AWS- \* runbooks) such as the `AWS-ConfigureS3BucketLogging`, `AWS-CreateDynamoDBBackup`, and `AWS-RestartEC2Instance` runbooks, to name a few. This requirement also applies to any custom Automation runbooks you create that invoke other AWS services by using actions that call other services. For example, if you use the `aws:executeAwsApi`, `aws:createStack`, or `aws:copyImage` actions, configure the service role with permission to invoke those services. You can give permissions to other AWS services by adding an IAM inline policy to the role. For more information, see [\(Optional\) Add an Automation inline policy or customer managed policy to invoke other AWS services](#).

For information about the actions that you can specify in a runbook, see [Systems Manager Automation actions reference](#).

For information about using the AWS Toolkit for Visual Studio Code to create runbooks, see [Working with Systems Manager Automation documents](#) in the *AWS Toolkit for Visual Studio Code User Guide*.

For information about using the visual designer to create a custom runbook, see [Visual design experience for Automation runbooks](#).

## Visual design experience for Automation runbooks

AWS Systems Manager Automation provides a low-code visual design experience that helps you create automation runbooks. The visual design experience provides a drag-and-drop interface with the option to add your own code so you can create and edit runbooks more easily. With the visual design experience, you can do the following:

- Control conditional statements.

- Control how input and output is filtered or transformed for each action.
- Configure error handling.
- Prototype new runbooks.
- Use your prototype runbooks as the starting point for local development with the AWS Toolkit for Visual Studio Code.

When you create or edit a runbook, you can access the visual design experience from the [Automation console](#). As you create a runbook, the visual design experience validates your work and auto-generates code. You can review the generated code, or export it for local development. When you're finished, you can save your runbook, run it, and examine the results in the Systems Manager Automation console.

### Before you begin

To use the visual design experience, you need an AWS account, and credentials that provide the correct permissions for any resources that you want to use.

In the visual design experience, Automation integrates with Amazon CodeGuru Security to help you detect security policy violations and vulnerabilities in your Python scripts. To use this feature for `aws:executeScript` actions, your AWS Identity and Access Management (IAM) policy must include the following permissions:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "codeguru-security:CreateUploadUrl",
        "codeguru-security:CreateScan",
        "codeguru-security:GetScan",
        "codeguru-security:GetFindings"
      ]
    }
  ]
}
```

### Topics

- [Overview of the visual design experience interface](#)

- [Using the visual design experience](#)
- [Configuring inputs and outputs for your actions](#)
- [Error handling with the visual design experience](#)
- [Tutorial: Create a runbook using the visual design experience](#)

## Overview of the visual design experience interface

The visual design experience for Systems Manager Automation is a low-code visual workflow designer that helps you create automation runbooks.

Get to know the visual design experience with an overview of the interface components:

- The **Actions** browser contains the **Actions**, **AWS APIs**, and **Runbooks** tabs.
- The *canvas* is where you drag and drop actions into your workflow graph, change the order of actions, and select actions to configure or view.
- The **Form** panel is where you can view and edit the properties of any action that you selected on the canvas. Select the **Content** toggle to view the YAML or JSON for your runbook, with the currently selected action highlighted.

**Info** links open a panel with contextual information when you need help. These panels also include links to related topics in the Systems Manager Automation documentation.

## Actions browser

From the **Actions** browser, you can select actions to drag and drop into your workflow graph. You can search all actions using the search field at the top of the **Actions** browser. The **Actions** browser contains the following tabs:

- The **Actions** tab provides a list of automation actions that you can drag and drop into your runbook's workflow graph in the canvas.
- The **AWS APIs** tab provides a list of AWS APIs that you can drag and drop into your runbook's workflow graph in the canvas.
- The **Runbooks** tab provides several ready-to-use, reusable runbooks as building blocks that you can use for a variety of use cases. For example, you can use runbooks to perform common remediation tasks on Amazon EC2 instances in your workflow without having to re-create the same actions.

## Canvas

After you choose an action to add to your automation, drag it to the canvas and drop it into your workflow graph. You can also drag and drop actions to move them to different places in your runbook's workflow. If your workflow is complex, you might not be able to view all of it in the

canvas panel. Use the controls at the top of the canvas to zoom in or out. To view different parts of a workflow, you can drag the workflow graph in the canvas.

Drag an action from the **Actions** browser, and drop it into your runbook's workflow graph. A line shows where it will be placed in your workflow. To change the order of an action, you can drag it to a different place in your workflow. The new action has been added to your workflow, and its code is auto-generated.

## Form

After you add an action to your runbook workflow, you can configure it to meet your use case. Choose the action that you want to configure, and you will see its parameters and options in the **Form** panel. You can also see the YAML or JSON code by choosing the **Content** toggle. The code associated with the action you have selected is highlighted.

← Back to Runbook attributes

**ExecutePythonScript3Times** Content

General | **Inputs** | Outputs | Configuration

Configure one or more inputs for the action type you selected. The input fields provided for you depend on the action type you selected for the step.

**Loop type**  
The type of loop: Do while or For each loop  
Do while

**Loop condition**  
The condition that Automation will evaluate before starting another loop iteration.  
Condition definition: `{{ RunHelloWorldSteps }} == true`

**Maximum iterations**  
The maximum number of times the steps in the loop run. Once the value specified for this input is reached, the loop stops running even if the LoopCondition is still true or if there are objects remaining in the Iterators parameter. The maximum value is 100.  
3

**Content (read-only)** Copy Content

```

1 schemaVersion: '0.3'
2 parameters:
3   AutomationAssumeRole:
4     type: AWS::IAM::Role::Arn
5     default: ''
6     description: (Optional) The ARN of the role that allows
7       Automation to perform the actions on your behalf.
8   RunHelloWorldSteps:
9     type: Boolean
10    description: Determines which branch of actions to run.
11  Approvers:
12    type: StringList
13    description: (Required) IAM user or user arn of approvers
14    for the automation action
15  assumeRole: '{{ AutomationAssumeRole }}'
16  description: |-
17    This sample runbook demonstrates the usage of the following
18    Automation actions:
19    * aws:branch
20    * aws:approve
21    * aws:sleep
22    * aws:loop
23    * aws:executeScript
24  mainSteps:
25  - name: Run_Hello_World_Steps
26    action: aws:branch
27    isEnd: true
28    inputs:
29      Choices:
30        - NextStep: RequestApprove
31          Variable: '{{ RunHelloWorldSteps }}'
32          BooleanEquals: true
  
```

### Keyboard shortcuts

The visual design experience supports the keyboard shortcuts shown in the following table.

## Keyboard shortcut

**Undo**  
The last operation.

**Redo**  
The last operation.

**Enter**  
The workflow in the canvas.

**Backspace**  
all selected states.

**Delete**  
all selected states.

**Duplicate**  
The selected state.

## Using the visual design experience

Learn to create, edit and run runbook workflows using the visual design experience. After your workflow is ready, you can save it or export it. You can also use the visual design experience for rapid prototyping.

### Create a runbook workflow

1. Sign in to the [Systems Manager Automation console](#).
2. Choose **Create runbook**.
3. In the **Name** box, enter a name for your runbook, for example, *MyNewRunbook*.
4. Next to the **Design** and **Code** toggle, select the pencil icon and enter a name for your runbook.

You can now design a workflow for your new runbook.

### Design a runbook

To design a runbook workflow using the visual design experience, you drag an automation action from the **Actions** browser into the canvas, placing it where you want it in your runbook's workflow. You can also re-order actions in your workflow by dragging them to a different location. As you drag an action onto the canvas, a line appears wherever you can drop the action in your workflow. After an action is dropped onto the canvas, its code is auto-generated and added inside your runbook's content.

If you know the name of the action you want to add, use the search box at the top of the **Actions** browser to find the action.

After you drop an action onto the canvas, configure it using the **Form** panel on the right. This panel contains the **General**, **Inputs**, **Outputs**, and **Configuration** tabs for each automation action or API action that you place on the canvas. For example, the **General** tab consists of the following sections:

- The **Step name** identifies the step. Specify a unique value for the step name.
- The **Description** helps you describe what the action is doing in your runbook's workflow.

The **Inputs** tab contains fields that vary based on the action. For example, the `aws:executeScript` automation action consists of the following sections:

- The **Runtime** is the language to use for running the provided script.
- The **Handler** is the name of your function. You must ensure that the function defined in the handler has two parameters: `events` and `context`. The PowerShell runtime doesn't support this parameter.
- The **Script** is an embedded script that you want to run during the workflow.
- (Optional) The **Attachment** is for standalone scripts or .zip files that can be invoked by the action. This parameter is required for JSON runbooks.

The **Outputs** tab helps you specify the values that you want to output from an action. You can reference output values in later actions of your workflow, or generate output from actions for logging purposes. Not all actions will have an **Outputs** tab because not all actions support outputs. For example, the `aws:pause` action doesn't support outputs. For actions that do support outputs, the **Outputs** tab consists of the following sections:

- The **Name** is the name to be used for the output value. You can reference outputs in later actions of your workflow.
- The **Selector** is a JSONPath expression string beginning with "\$ ." that is used to select one or more components within a JSON element.
- The **Type** is the data type for the output value. For example, a `String` or `Integer` data type.

The **Configuration** tab contains properties and options that all automation actions can use. The action consists of the following sections:

- The **Max attempts** property is the number of times an action retries if it fails.
- The **Timeout seconds** property specifies the timeout value for an action.
- The **Is critical** property determines if the action failure stops the entire automation.
- The **Next step** property determines which action the automation goes to next in the runbook.
- The **On failure** property determines which action the automation goes to next in the runbook if the action fails.
- The **On cancel** property determines which action the automation goes to next in the runbook if the action is canceled by a user.

To delete an action, you can use backspace, the toolbar above the canvas, or right-click and choose **Delete action**.

As your workflow grows, it might not fit in the canvas. To help make the workflow fit in the canvas, try one of the following options:

- Use the controls on the side panels to resize or close the panels.
- Use the toolbar at the top of the canvas to zoom the workflow graph in or out.

## Update your runbook

You can update an existing runbook workflow by creating a new version of your runbook. Updates to your runbooks can be made by using the visual design experience, or by editing the code directly. To update an existing runbook, use the following procedure:

1. Sign in to the [Systems Manager Automation console](#).
2. Choose the runbook that you want to update.
3. Choose **Create new version**.
4. The visual design experience has two panes: A code pane and a visual workflow pane. Choose **Design** in the visual workflow pane to edit your workflow with the visual design experience. When you're done, choose **Create new version** to save your changes and exit.
5. (Optional) Use the code pane to edit the runbook content in YAML or JSON.

## Export your runbook

To export your runbook's workflow YAML or JSON code, and also a graph of your workflow, use the following procedure:

1. Choose your runbook in the **Documents** console.
2. Choose **Create new version**.
3. In the **Actions** dropdown, choose whether you want to export the graph or runbook, and which format you prefer.

## Configuring inputs and outputs for your actions

Each automation action responds based on input that it receives. In most cases, you then pass output to the subsequent actions. In the visual design experience, you can configure an action's input and output data in the **Inputs** and **Outputs** tabs of the **Form** panel.

For detailed information about how to define and use output for automation actions, see [Using action outputs as inputs](#).

## Provide input data for an action

Each automation action has one or more inputs that you must provide a value for. The value you provide for an action's input is determined by the data type and format that's accepted by the action. For example, the `aws:sleep` action requires an ISO 8601 formatted string value for the `Duration` input.

Generally, you use actions in your runbook's workflow that return output that you want to use in subsequent actions. It's important to make sure your input values are correct to avoid errors in your runbook's workflow. Input values are also important because they determine whether the action returns the expected output. For example, when using the `aws:executeAwsApi` action, you want to make sure that you're providing the right value for the API operation.

## Define output data for an action

Some automation actions return output after performing their defined operations. Actions that return output either have predefined outputs, or allow you to define the outputs yourself. For example, the `aws:createImage` action has predefined outputs that return an `ImageId` and `ImageState`. Comparatively, with the `aws:executeAwsApi` action, you can define the outputs you want from the specified API operation. As a result, you can return one or more values from a single API operation to use in subsequent actions.

Defining your own outputs for an automation action requires that you specify a name of the output, the data type, and the output value. To continue using the `aws:executeAwsApi` action as an example, let's say you're calling the `DescribeInstances` API operation from Amazon EC2. In this example, you want to return, or output, the `State` of an Amazon EC2 instance and branch your runbook's workflow based on the output. You choose to name the output **InstanceState**, and use the **String** data type.

The process to define the actual value of the output differs, depending on the action. For example, if you're using the `aws:executeScript` action, you must use `return` statements in your functions to provide data to your outputs. With other actions like `aws:executeAwsApi`, `aws:waitForAwsResourceProperty`, and `aws:assertAwsResourceProperty`, a `Selector` is required. The `Selector`, or `PropertySelector` as some actions refer to it, is a `JSONPath` string that is used to process the JSON response from an API operation. It's important to understand how the JSON response object from an API operation is structured so you can select the correct

value for your output. Using the DescribeInstances API operation mentioned earlier, see the following example JSON response:

```
{
  "reservationSet": {

    "coreCount": 1,
    "threadsPerCore": 1
}
}
}
}
```

```
}
```

In the JSON response object, the instance State is nested in an Instances object, which is nested in the Reservations object. To return the value of the instance State, use the following string for the Selector so the value can be used in our output:

```
$.Reservations[0].Instances[0].State.Name.
```

To reference an output value in subsequent actions of your runbook's workflow, the following format is used: `{{ StepName.NameOfOutput }}`. For example, `{{ GetInstanceState.InstanceState }}`. In the visual design experience, you can choose output values to use in subsequent actions using the dropdown for the input. When using outputs in subsequent actions, the data type of the output must match the data type for the input. In this example, the InstanceState output is a String. Therefore, to use the value in a subsequent action's input, the input must accept a String.

### Error handling with the visual design experience

By default, when an action reports an error, Automation stops the runbook's workflow entirely. This is because the default value for the onFailure property on all actions is Abort. You can configure how Automation handles errors in your runbook's workflow. Even if you have configured error handling, some errors might still cause an automation to fail. For more information, see [Troubleshooting Systems Manager Automation](#). In the visual design experience, you configure error handling in the **Configuration** panel.

## getInstanceState Content >

**General** | **Inputs** | **Outputs** | **Configuration**

The following properties define execution behavior for a step. For example, how long to wait for a step to complete and what to do if it fails. [Learn more](#)

**Max attempts**

Valid characters include integers only

**Timeout seconds**

Valid characters include integers only

**Is critical**

**Next step**

**On failure**

**On cancel**

## Retry action on error

To retry an action in case of an error, specify a value for the **Max attempts** property. The default value is 1. If you specify a value greater than 1, the action isn't considered to have failed until all of the retry attempts have failed.

## Timeouts

You can configure a timeout for actions to set the maximum number of seconds your action can run before it fails. To configure a timeout, enter the number of seconds that your action should wait before the action fails in the **Timeout seconds** property. If the timeout is reached and the

action has a value of `Max attempts` that is greater than 1, the step isn't considered to have timed out until the retries complete.

## Failed actions

By default, when an action fails, Automation stops the runbook's workflow entirely. You can modify this behavior by specifying an alternative value for the **On failure** property of the actions in your runbook. If you want the workflow to continue to the next step in the runbook, choose **Continue**. If you want the workflow to jump to a different subsequent step in the runbook, choose **Step** and then enter the name of the step.

## Canceled actions

By default, when an action is canceled by a user, Automation stops the runbook's workflow entirely. You can modify this behavior by specifying an alternative value for the **On cancel** property of the actions in your runbook. If you want the workflow to jump to a different subsequent step in the runbook, choose **Step** and then enter the name of the step.

## Critical actions

You can designate an action as *critical*, meaning it determines the overall reporting status of your automation. If a step with this designation fails, Automation reports the final status as `Failed` regardless of the success of other actions. To configure an action as critical, leave the default value as **True** for the **Is critical** property.

## Ending actions

The **Is end** property stops an automation at the end of the specified action. The default value for this property is `false`. If you configure this property for an action, the automation stops whether the action succeeds or fails. This property is most often used with `aws:branch` actions to handle unexpected or undefined input values. The following example shows a runbook that is expecting an instance state of either `running`, `stopping`, or `stopped`. If an instance is in a different state, the automation ends.

**branchOnInstanceState**

```
- name: branchOnInstanceState
  action: aws:branch
  isEnd: true
  inputs:
    Choices:
      - NextStep: startInstance
        Variable: '{{getInstanceState.instanceState}}'
        StringEquals: stopped
      - NextStep: verifyInstanceStopped
        Variable: '{{getInstanceState.instanceState}}'
        StringEquals: stopping
      - NextStep: patchInstance
        Variable: '{{getInstanceState.instanceState}}'
        StringEquals: running
```

## Tutorial: Create a runbook using the visual design experience

In this tutorial, you will learn the basics of working with the visual design experience provided by Systems Manager Automation. In the visual design experience, you can create a runbook that uses multiple actions. You use the drag and drop feature to arrange actions on the canvas. You also search for, select, and configure these actions. Then, you can view the auto-generated YAML code for your runbook's workflow, exit the visual design experience, run the runbook, and review the execution details.

This tutorial also shows you how to update the runbook and view the new version. At the end of the tutorial, you perform a clean-up step and delete your runbook.

After you complete this tutorial, you'll know how to use the visual design experience to create a runbook. You'll also know how to update, run, and delete your runbook.

**Note**

Before you start this tutorial, make sure to complete [Setting up Automation](#).

**Topics**

- [Step 1: Navigate to the visual design experience](#)
- [Step 2: Create a workflow](#)
- [Step 3: Review the auto-generated code](#)
- [Step 4: Run your new runbook](#)
- [Step 5: Clean up](#)

**Step 1: Navigate to the visual design experience**

1. Sign in to the [Systems Manager Automation console](#).
2. Choose **Create automation runbook**.

**Step 2: Create a workflow**

In the visual design experience, a workflow is a graphical representation of your runbook on the canvas. You can use the visual design experience to define, configure, and examine the individual actions of your runbook.

**To create a workflow**

1. Next to the **Design** and **Code** toggle, select the pencil icon and enter a name for your runbook. For this tutorial, enter **VisualDesignExperienceTutorial**.

**Design**

Code

2. In the **Document attributes** section of the **Form** panel, expand the **Input parameters** dropdown, and select **Add a parameter**.
  - a. In the **Parameter name** field, enter **InstanceId**.
  - b. In the **Type** dropdown, choose **AWS::EC2::Instance**.
  - c. Select the **Required** toggle.

# Runbook attributes

Attributes **2**

Parameters **1**

Variables

✕ Close

**Parameter name**  
Enter a unique name.

**Type**  
Specify a data type.

**Required**  
Specify if the parameter is required.

3. In the **AWS APIs** browser, enter **DescribeInstances** in the search bar.
4. Drag an **Amazon EC2 – DescribeInstances** action to the empty canvas.
5. For **Step name**, enter a value. For this tutorial, you can use the name **GetInstanceState**.

**GetInstanceState**  Content >

**General** | Inputs | Outputs | Configuration

**Step name**  
Enter a unique name for this step

Between 3 and 128 characters, alphanumeric characters and `_` only.

**Action type**  
aws:executeAwsApi

**Description**  
Enter information to describe the purpose or usage of this step. Use Markdown to format the content.

**Markdown preview**

- a. Expand the **Additional inputs** dropdown, and in the **Input name** field, enter **InstanceIds**.
  - b. Choose the **Inputs** tab.
  - c. In the **Input value** field, choose the **InstanceId** document input. This references the value of the input parameter that you created at the beginning of the procedure. Since the **InstanceIds** input for the `DescribeInstances` action accepts `StringList` values, you must wrap the **InstanceId** input in square brackets. The YAML for the **Input value** should match the following: `[ '{{ InstanceId }} ]'`.
  - d. In the **Outputs** tab, select **Add an output** and enter **InstanceState** in the **Name** field.
  - e. In the **Selector** field, enter `$.Reservations[0].Instances[0].State.Name`.
  - f. In the **Type** dropdown, choose **String**.
6. Drag a **Branch** action from the **Actions** browser, and drop it below the **GetInstanceState** step.
  7. For **Step name**, enter a value. For this tutorial, use the name **BranchOnInstanceState**.

To define the branching logic, do the following:

- a. Choose the **Branch** state on the canvas. Then, under **Inputs** and **Choices**, select the pencil icon to edit **Rule #1**.
- b. Choose **Add conditions**.
- c. In the **Conditions for rule #1** dialog box, choose the **GetInstanceState.InstanceState** step output from the **Variable** dropdown.
- d. For **Operator**, choose **is equal to**.
- e. For **Value**, choose **String** from the dropdown list. Enter **stopped**.

**Conditions for choice #1** ✕

Choice rules are conditional statements that the Automation evaluates when determining the next step to process. [Learn more](#)

Simple  
Evaluates a single conditional statement.

| Not | Variable                             | Operator    | Value             |
|-----|--------------------------------------|-------------|-------------------|
| ▼   | {{ GetInstanceState.InstanceState }} | is equal to | String<br>stopped |

Cancel Save conditions

- f. Select **Save conditions**.
- g. Choose **Add new choice rule**.
- h. Choose **Add conditions for Rule #2**.

- i. In the **Conditions for rule #2** dialog box, choose the **GetInstanceState.InstanceState** step output from the **Variable** dropdown.
  - j. For **Operator**, choose **is equal to**.
  - k. For **Value**, choose **String** from the dropdown list. Enter **stopping**.
  - l. Select **Save conditions**.
  - m. Choose **Add new choice rule**.
  - n. For **Rule #3**, choose **Add conditions**.
  - o. In the **Conditions for rule #3** dialog box, choose the **GetInstanceState.InstanceState** step output from the **Variable** dropdown.
  - p. For **Operator**, choose **is equal to**.
  - q. For **Value**, choose **String** from the dropdown list. Enter **running**.
  - r. Select **Save conditions**.
  - s. In the **Default rule**, choose **Go to end** for the **Default step**.
8. Drag a **Change an instance state** action to the empty **Drag action here** box under the **{{ GetInstanceState.InstanceState }} == "stopped"** condition.
- a. For the **Step name**, enter **StartInstance**.
  - b. In the **Inputs** tab, under **Instance IDs**, choose the **InstanceId** document input value from the dropdown.
  - c. For the **Desired state**, specify **running**.
9. Drag a **Wait on AWS resource** action to the empty **Drag action here** box under the **{{ GetInstanceState.InstanceState }} == "stopping"** condition.
10. For **Step name**, enter a value. For this tutorial, use the name **WaitForInstanceStop**.
- a. For the **Service** field, choose **Amazon EC2**.
  - b. For the **API** field, choose **DescribeInstances**.
  - c. For the **Property selector** field, enter **\$.Reservations[0].Instances[0].State.Name**.
  - d. For the **Desired values** parameter, enter **["stopped"]**.
  - e. In the **Configuration** tab of the **WaitForInstanceStop** action, choose **StartInstance** from the **Next step** dropdown.
11. Drag a **Run command on instances** action to the empty **Drag action here** box under the **{{ GetInstanceState.InstanceState }} == "running"** condition.

## 12. For the **Step name**, enter **SayHello**.

- In the **Inputs** tab, enter **AWS-RunShellScript** for the **Document name** parameter.
- For **InstanceIds**, choose the **InstanceId** document input value from the dropdown.
- Expand the **Additional inputs** dropdown, and in the **Input name** dropdown, choose **Parameters**.
- In the **Input value** field, enter `{"commands": "echo 'Hello World'"}`.

## 13. Review the completed runbook in the canvas and select **Create runbook** to save the tutorial runbook.

The screenshot displays the AWS Systems Manager Runbook Designer interface. The main canvas shows a visual flowchart for a runbook. The flow starts at a 'Start' node, followed by an 'aws:executeAwsApi EC2: DescribeInstances GetInstanceState' action. This leads to a 'BranchOnInstanceState' action. The flow then branches into two paths: one leading to 'aws:changeInstanceState StartInstance' and another to 'aws:waitForAwsResourceProperty WaitForInstanceStop'. Both paths converge at an 'End' node. A 'SayHello' action is also present. The right sidebar shows 'Runbook attributes' with a 'Parameters' tab active, displaying a parameter named 'InstanceId' of type 'AWS::EC2::Instance:Id'.

### Step 3: Review the auto-generated code

As you drag and drop actions from the **Actions** browser onto the canvas, the visual design experience automatically composes the YAML or JSON content of your runbook in real-time. You can view and edit this code. To view the auto-generated code, select **Code** for the **Design** and **Code** toggle.

### Step 4: Run your new runbook

After creating your runbook, you can run the automation.

#### To run your new automation runbook

- Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.

2. In the navigation pane, choose **Automation**, and then choose **Execute automation**.
3. In the **Automation document** list, choose a runbook. Choose one or more options in the **Document categories** pane to filter SSM documents according to their purpose. To view a runbook that you own, choose the **Owned by me** tab. To view a runbook that is shared with your account, choose the **Shared with me** tab. To view all runbooks, choose the **All documents** tab.

 **Note**

You can view information about a runbook by choosing the runbook name.

4. In the **Document details** section, verify that **Document version** is set to the version that you want to run. The system includes the following version options:
  - **Default version at runtime** – Choose this option if the Automation runbook is updated periodically and a new default version is assigned.
  - **Latest version at runtime** – Choose this option if the Automation runbook is updated periodically, and you want to run the version that was most recently updated.
  - **1 (Default)** – Choose this option to run the first version of the document, which is the default.
5. Choose **Next**.
6. In the **Execute automation runbook** section, choose **Simple execution**.
7. In the **Input parameters** section, specify the required inputs. Optionally, you can choose an IAM service role from the **AutomationAssumeRole** list.
8. (Optional) Choose an Amazon CloudWatch alarm to apply to your automation for monitoring. To attach a CloudWatch alarm to your automation, the IAM principal that starts the automation must have permission for the `iam:createServiceLinkedRole` action. For more information about CloudWatch alarms, see [Using Amazon CloudWatch alarms](#). If your alarm activates, the automation is stopped. If you use AWS CloudTrail, you will see the API call in your trail.
9. Choose **Execute**.

## Step 5: Clean up

### To delete your runbook

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Documents**.
3. Select the **Owned by me** tab.
4. Locate the **VisualDesignExperienceTutorial** runbook.
5. Select the button on the document card page, and then choose **Delete document** from the **Actions** dropdown.

### Authoring Automation runbooks

Each runbook in Automation, a capability of AWS Systems Manager, defines an automation. Automation runbooks define the actions that are performed during an automation. In the runbook content, you define the input parameters, outputs, and actions that Systems Manager performs on your managed instances and AWS resources.

Automation includes several pre-defined runbooks that you can use to perform common tasks like restarting one or more Amazon Elastic Compute Cloud (Amazon EC2) instances or creating an Amazon Machine Image (AMI). However, your use cases might extend beyond the capabilities of the pre-defined runbooks. If this is the case, you can create your own runbooks and modify them to your needs.

A runbook consists of automation actions, parameters for those actions, and input parameters that you specify. A runbook's content is written in either YAML or JSON. If you're not familiar with either YAML or JSON, we recommend using the visual designer, or learning more about either markup language before attempting to author your own runbook. For more information about the visual designer, see [Visual design experience for Automation runbooks](#).

The following sections will help you author your first runbook.

### Identify your use case

The first step in authoring a runbook is identifying your use case. For example, you scheduled the `AWS-CreateImage` runbook to run daily on all of your production Amazon EC2 instances. At the end of the month, you decide you have more images than are necessary for recovery points. Going

forward, you want to automatically delete the oldest AMI of an Amazon EC2 instance when a new AMI is created. To accomplish this, you create a new runbook that does the following:

1. Runs the `aws:createImage` action and specifies the instance ID in the image description.
2. Runs the `aws:waitForAwsResourceProperty` action to poll the state of the image until it's available.
3. After the image state is available, the `aws:executeScript` action runs a custom Python script that gathers the IDs of all images associated with your Amazon EC2 instance. The script does this by filtering, using the instance ID in the image description you specified at creation. Then, the script sorts the list of image IDs based on the `creationDate` of the image and outputs the ID of the oldest AMI.
4. Lastly, the `aws:deleteImage` action runs to delete the oldest AMI using the ID from the output of the previous step.

In this scenario, you were already using the `AWS-CreateImage` runbook but found that your use case required greater flexibility. This is a common situation because there can be overlap between runbooks and automation actions. As a result, you might have to adjust which runbooks or actions you use to address your use case.

For example, the `aws:executeScript` and `aws:invokeLambdaFunction` actions both allow you to run custom scripts as part of your automation. To choose between them, you might prefer `aws:invokeLambdaFunction` because of the additional supported runtime languages. However, you might prefer `aws:executeScript` because it allows you to author your script content directly in YAML runbooks and provide script content as attachments for JSON runbooks. You might also consider `aws:executeScript` to be simpler in terms of AWS Identity and Access Management (IAM) setup. Because it uses the permissions provided in the `AutomationAssumeRole`, `aws:executeScript` doesn't require an additional AWS Lambda function execution role.

In any given scenario, one action might provide more flexibility, or added functionality, over another. Therefore, we recommend that you review the available input parameters for the runbook or action you want to use to determine which best fits your use case and preferences.

## Set up your development environment

After you've identified your use case and the pre-defined runbooks or automation actions you want to use in your runbook, it's time to set up your development environment for the content of your

runbook. To develop your runbook content, we recommend using the AWS Toolkit for Visual Studio Code instead of the Systems Manager Documents console.

The Toolkit for VS Code is an open-source extension for Visual Studio Code (VS Code) that offers more features than the Systems Manager Documents console. Helpful features include schema validation for both YAML and JSON, snippets for automation action types, and auto-complete support for various options in both YAML and JSON.

For more information about installing the Toolkit for VS Code, see [Installing the AWS Toolkit for Visual Studio Code](#). For more information about using the Toolkit for VS Code to develop runbooks, see [Working with Systems Manager Automation documents](#) in the *AWS Toolkit for Visual Studio Code User Guide*.

## Develop runbook content

With your use case identified and environment set up, you're ready to develop the content for your runbook. Your use case and preferences will largely dictate the automation actions or runbooks you use in your runbook content. Some actions support only a subset of input parameters when compared to another action that allows you to accomplish a similar task. Other actions have specific outputs, such as `aws:createImage`, where some actions allow you to define your own outputs, such as `aws:executeAwsApi`.

If you're unsure how to use a particular action in your runbook, we recommend reviewing the corresponding entry for the action in the [Systems Manager Automation actions reference](#). We also recommend reviewing the content of pre-defined runbooks to see real-world examples of how these actions are used. For more examples of real-world applications of runbooks, see [Additional runbook examples](#).

To demonstrate the differences in simplicity and flexibility that runbook content provides, the following tutorials provide an example of how to patch groups of Amazon EC2 instances in stages:

- [the section called “Example 1: Creating parent-child runbooks”](#) – In this example, two runbooks are used in a parent-child relationship. The parent runbook initiates a rate control automation of the child runbook.
- [the section called “Example 2: Scripted runbook”](#) – This example demonstrates how you can accomplish the same tasks of Example 1 by condensing the content into a single runbook and using scripts in your runbook.

## Example 1: Creating parent-child runbooks

The following example demonstrates how to create two runbooks that patch tagged groups of Amazon Elastic Compute Cloud (Amazon EC2) instances in stages. These runbooks are used in a parent-child relationship with the parent runbook used to initiate a rate control automation of the child runbook. For more information about rate control automations, see [Run automated operations at scale](#). For more information about the automation actions used in this example, see the [Systems Manager Automation actions reference](#).

### Create the child runbook

This example runbook addresses the following scenario. Emily is a Systems Engineer at AnyCompany Consultants, LLC. She needs to configure patching for groups of Amazon Elastic Compute Cloud (Amazon EC2) instances that host primary and secondary databases. Applications access these databases 24 hours a day, so one of the database instances must always be available.

She decides that patching the instances in stages is the best approach. The primary group of database instances will be patched first, followed by the secondary group of database instances. Also, to avoid incurring additional costs by leaving instances running that were previously stopped, Emily wants the patched instances to be returned to their original state before the patching occurred.

Emily identifies the primary and secondary groups of database instances by the tags associated with the instances. She decides to create a parent runbook that starts a rate control automation of a child runbook. By doing that, she can target the tags associated with the primary and secondary groups of database instances and manage the concurrency of the child automations. After reviewing the available Systems Manager (SSM) documents for patching, she chooses the `AWS-RunPatchBaseline` document. By using this SSM document, her colleagues can review the associated patch compliance information after the patching operation completes.

To start creating her runbook content, Emily reviews the available automation actions and begins authoring the content for the child runbook as follows:

1. First, she provides values for the schema and description of the runbook, and defines the input parameters for the child runbook.

By using the `AutomationAssumeRole` parameter, Emily and her colleagues can use an existing IAM role that allows Automation to perform the actions in the runbook on their behalf. Emily uses the `InstanceId` parameter to determine the instance that should be patched. Optionally, the `Operation`, `RebootOption`, and `SnapshotId` parameters can be used to provide values

to document parameters for `AWS-RunPatchBaseline`. To prevent invalid values from being provided to those document parameters, she defines the `allowedValues` as needed.

## YAML

```
schemaVersion: '0.3'
description: 'An example of an Automation runbook that patches groups of Amazon
  EC2 instances in stages.'
assumeRole: '{{AutomationAssumeRole}}'
parameters:
  AutomationAssumeRole:
    type: String
    description: >-
      '(Optional) The Amazon Resource Name (ARN) of the IAM role that allows
  Automation to perform the
      actions on your behalf. If no role is specified, Systems Manager
  Automation uses your IAM permissions to operate this runbook.'
    default: ''
  InstanceId:
    type: String
    description: >-
      '(Required) The instance you want to patch.'
  SnapshotId:
    type: String
    description: '(Optional) The snapshot ID to use to retrieve a patch baseline
  snapshot.'
    default: ''
  RebootOption:
    type: String
    description: '(Optional) Reboot behavior after a patch Install operation. If
  you choose NoReboot and patches are installed, the instance is marked as non-
  compliant until a subsequent reboot and scan.'
    allowedValues:
      - NoReboot
      - RebootIfNeeded
    default: RebootIfNeeded
  Operation:
    type: String
    description: '(Optional) The update or configuration to perform on the
  instance. The system checks if patches specified in the patch baseline are
  installed on the instance. The install operation installs patches missing from
  the baseline.'
    allowedValues:
      - Install
```

```
- Scan
default: Install
```

## JSON

```
{
  "schemaVersion":"0.3",
  "description":"An example of an Automation runbook that patches groups of
Amazon EC2 instances in stages.",
  "assumeRole":"{{AutomationAssumeRole}}",
  "parameters":{
    "AutomationAssumeRole":{
      "type":"String",
      "description":"(Optional) The Amazon Resource Name (ARN) of the IAM role
that allows Automation to perform the actions on your behalf. If no role is
specified, Systems Manager Automation uses your IAM permissions to operate this
runbook.",
      "default":""
    },
    "InstanceId":{
      "type":"String",
      "description":"(Required) The instance you want to patch."
    },
    "SnapshotId":{
      "type":"String",
      "description":"(Optional) The snapshot ID to use to retrieve a patch
baseline snapshot.",
      "default":""
    },
    "RebootOption":{
      "type":"String",
      "description":"(Optional) Reboot behavior after a patch Install
operation. If you choose NoReboot and patches are installed, the instance is
marked as non-compliant until a subsequent reboot and scan.",
      "allowedValues":[
        "NoReboot",
        "RebootIfNeeded"
      ],
      "default":"RebootIfNeeded"
    },
    "Operation":{
      "type":"String",
```

```

        "description":"(Optional) The update or configuration to perform on
the instance. The system checks if patches specified in the patch baseline are
installed on the instance. The install operation installs patches missing from
the baseline.",
        "allowedValues":[
            "Install",
            "Scan"
        ],
        "default":"Install"
    }
}
},

```

2. With the top-level elements defined, Emily proceeds with authoring the actions that make up the `mainSteps` of the runbook. The first step outputs the current state of the target instance specified in the `InstanceId` input parameter using the `aws:executeAwsApi` action. The output of this action is used in later actions.

## YAML

```

mainSteps:
  - name: getInstanceState
    action: 'aws:executeAwsApi'
    onFailure: Abort
    inputs:
      inputs:
        Service: ec2
        Api: DescribeInstances
        InstanceIds:
          - '{{InstanceId}}'
    outputs:
      - Name: instanceState
        Selector: '$.Reservations[0].Instances[0].State.Name'
        Type: String
    nextStep: branchOnInstanceState

```

## JSON

```

"mainSteps": [
  {
    "name": "getInstanceState",
    "action": "aws:executeAwsApi",
    "onFailure": "Abort",

```

```

    "inputs":{
      "inputs":null,
      "Service":"ec2",
      "Api":"DescribeInstances",
      "InstanceIds":[
        "{{InstanceId}}"
      ]
    },
    "outputs":[
      {
        "Name":"instanceState",
        "Selector":"$.Reservations[0].Instances[0].State.Name",
        "Type":"String"
      }
    ],
    "nextStep":"branchOnInstanceState"
  },

```

3. Rather than manually starting and keeping track of the original state of every instance that needs to be patched, Emily uses the output from the previous action to branch the automation based on the state of the target instance. This allows the automation to run different steps depending on the conditions defined in the `aws:branch` action and improves the overall efficiency of the automation without manual intervention.

If the instance state is already `running`, the automation proceeds with patching the instance with the `AWS-RunPatchBaseline` document using the `aws:runCommand` action.

If the instance state is `stopping`, the automation polls for the instance to reach the `stopped` state using the `aws:waitForAwsResourceProperty` action, starts the instance using the `executeAwsApi` action, and polls for the instance to reach a `running` state before patching the instance.

If the instance state is `stopped`, the automation starts the instance and polls for the instance to reach a `running` state before patching the instance using the same actions.

#### YAML

```

- name: branchOnInstanceState
  action: 'aws:branch'
  onFailure: Abort
  inputs:
    Choices:

```

```
- NextStep: startInstance
  Variable: '{{getInstanceState.instanceState}}'
  StringEquals: stopped
- NextStep: verifyInstanceStopped
  Variable: '{{getInstanceState.instanceState}}'
  StringEquals: stopping
- NextStep: patchInstance
  Variable: '{{getInstanceState.instanceState}}'
  StringEquals: running
isEnd: true
- name: startInstance
  action: 'aws:executeAwsApi'
  onFailure: Abort
  inputs:
    Service: ec2
    Api: StartInstances
    InstanceIds:
      - '{{InstanceId}}'
  nextStep: verifyInstanceRunning
- name: verifyInstanceRunning
  action: 'aws:waitForAwsResourceProperty'
  timeoutSeconds: 120
  inputs:
    Service: ec2
    Api: DescribeInstances
    InstanceIds:
      - '{{InstanceId}}'
    PropertySelector: '$.Reservations[0].Instances[0].State.Name'
    DesiredValues:
      - running
  nextStep: patchInstance
- name: verifyInstanceStopped
  action: 'aws:waitForAwsResourceProperty'
  timeoutSeconds: 120
  inputs:
    Service: ec2
    Api: DescribeInstances
    InstanceIds:
      - '{{InstanceId}}'
    PropertySelector: '$.Reservations[0].Instances[0].State.Name'
    DesiredValues:
      - stopped
  nextStep: startInstance
- name: patchInstance
```

```

action: 'aws:runCommand'
onFailure: Abort
timeoutSeconds: 5400
inputs:
  DocumentName: 'AWS-RunPatchBaseline'
  InstanceIds:
  - '{{InstanceId}}'
  Parameters:
    SnapshotId: '{{SnapshotId}}'
    RebootOption: '{{RebootOption}}'
    Operation: '{{Operation}}'

```

## JSON

```

        "Parameters": {
          "SnapshotId": "{{SnapshotId}}",
          "RebootOption": "{{RebootOption}}",
          "Operation": "{{Operation}}"
        }
      }
    }
  },
},

```

4. After the patching operation completes, Emily wants the automation to return the target instance to the same state it was in before the automation started. She does this by again using the output from the first action. The automation branches based on the original state of the target instance using the `aws:branch` action. If the instance was previously in any state other than `running`, the instance is stopped. Otherwise, if the instance state is `running`, the automation ends.

#### YAML

```

- name: branchOnOriginalInstanceState
  action: 'aws:branch'
  onFailure: Abort
  inputs:
    Choices:
      - NextStep: stopInstance
      Not:
        Variable: '{{getInstanceState.instanceState}}'
        StringEquals: running
  isEnd: true
- name: stopInstance
  action: 'aws:executeAwsApi'
  onFailure: Abort

```

```

inputs:
  Service: ec2
  Api: StopInstances
  InstanceIds:
    - '{{InstanceId}}'

```

## JSON

```

{
  "name": "branchOnOriginalInstanceState",
  "action": "aws:branch",
  "onFailure": "Abort",
  "inputs": {
    "Choices": [
      {
        "NextStep": "stopInstance",
        "Not": {
          "Variable": "{{getInstanceState.instanceState}}",
          "StringEquals": "running"
        }
      }
    ]
  },
  "isEnd": true
},
{
  "name": "stopInstance",
  "action": "aws:executeAwsApi",
  "onFailure": "Abort",
  "inputs": {
    "Service": "ec2",
    "Api": "StopInstances",
    "InstanceIds": [
      "{{InstanceId}}"
    ]
  }
}
]
}

```

- Emily reviews the completed child runbook content and creates the runbook in the same AWS account and AWS Region as the target instances. Now she's ready to continue with the creation of the parent runbook's content. The following is the completed child runbook content.

## YAML

```
schemaVersion: '0.3'
description: 'An example of an Automation runbook that patches groups of Amazon
  EC2 instances in stages.'

}

```

For more information about the automation actions used in this example, see the [Systems Manager Automation actions reference](#).

## Create the parent runbook

This example runbook continues the scenario described in the previous section. Now that Emily has created the child runbook, she begins authoring the content for the parent runbook as follows:

1. First, she provides values for the schema and description of the runbook, and defines the input parameters for the parent runbook.

By using the `AutomationAssumeRole` parameter, Emily and her colleagues can use an existing IAM role that allows Automation to perform the actions in the runbook on their behalf. Emily

uses the `PatchGroupPrimaryKey` and `PatchGroupPrimaryValue` parameters to specify the tag associated with the primary group of database instances that will be patched. She uses the `PatchGroupSecondaryKey` and `PatchGroupSecondaryValue` parameters to specify the tag associated with the secondary group of database instances that will be patched.

## YAML

```
description: 'An example of an Automation runbook that patches groups of Amazon
  EC2 instances in stages.'
schemaVersion: '0.3'
assumeRole: '{{AutomationAssumeRole}}'
parameters:
  AutomationAssumeRole:
    type: String
    description: '(Optional) The Amazon Resource Name (ARN) of the IAM role that
      allows Automation to perform the actions on your behalf. If no role is specified,
      Systems Manager Automation uses your IAM permissions to operate this runbook.'
    default: ''
  PatchGroupPrimaryKey:
    type: String
    description: '(Required) The key of the tag for the primary group of instances
      you want to patch.'
  PatchGroupPrimaryValue:
    type: String
    description: '(Required) The value of the tag for the primary group of
      instances you want to patch.'
  PatchGroupSecondaryKey:
    type: String
    description: '(Required) The key of the tag for the secondary group of
      instances you want to patch.'
  PatchGroupSecondaryValue:
    type: String
    description: '(Required) The value of the tag for the secondary group of
      instances you want to patch.'
```

## JSON

```
{
  "schemaVersion": "0.3",
  "description": "An example of an Automation runbook that patches groups of
  Amazon EC2 instances in stages.",
  "assumeRole": "{{AutomationAssumeRole}}",
  "parameters": {
```

```
    "AutomationAssumeRole": {
      "type": "String",
      "description": "(Optional) The Amazon Resource Name (ARN) of the IAM
role that allows Automation to perform the actions on your behalf. If no role is
specified, Systems Manager Automation uses your IAM permissions to operate this
runbook.",
      "default": ""
    },
    "PatchGroupPrimaryKey": {
      "type": "String",
      "description": "(Required) The key of the tag for the primary group of
instances you want to patch."
    },
    "PatchGroupPrimaryValue": {
      "type": "String",
      "description": "(Required) The value of the tag for the primary group of
instances you want to patch."
    },
    "PatchGroupSecondaryKey": {
      "type": "String",
      "description": "(Required) The key of the tag for the secondary group of
instances you want to patch."
    },
    "PatchGroupSecondaryValue": {
      "type": "String",
      "description": "(Required) The value of the tag for the secondary group
of instances you want to patch."
    }
  }
},
```

2. With the top-level elements defined, Emily proceeds with authoring the actions that make up the `mainSteps` of the runbook.

The first action starts a rate control automation using the child runbook she just created that targets instances associated with the tag specified in the `PatchGroupPrimaryKey` and `PatchGroupPrimaryValue` input parameters. She uses the values provided to the input parameters to specify the key and value of the tag associated with the primary group of database instances she wants to patch.

After the first automation completes, the second action starts another rate control automation using the child runbook that targets instances associated with the tag specified in the

PatchGroupSecondaryKey and PatchGroupSecondaryValue input parameters. She uses the values provided to the input parameters to specify the key and value of the tag associated with the secondary group of database instances she wants to patch.

## YAML

```
mainSteps:
  - name: patchPrimaryTargets
    action: 'aws:executeAutomation'
    onFailure: Abort
    timeoutSeconds: 7200
    inputs:
      DocumentName: RunbookTutorialChildAutomation
      Targets:
        - Key: 'tag:{{PatchGroupPrimaryKey}}'
          Values:
            - '{{PatchGroupPrimaryValue}}'
      TargetParameterName: 'InstanceId'
  - name: patchSecondaryTargets
    action: 'aws:executeAutomation'
    onFailure: Abort
    timeoutSeconds: 7200
    inputs:
      DocumentName: RunbookTutorialChildAutomation
      Targets:
        - Key: 'tag:{{PatchGroupSecondaryKey}}'
          Values:
            - '{{PatchGroupSecondaryValue}}'
      TargetParameterName: 'InstanceId'
```

## JSON

```
"mainSteps": [
  {
    "name": "patchPrimaryTargets",
    "action": "aws:executeAutomation",
    "onFailure": "Abort",
    "timeoutSeconds": 7200,
    "inputs": {
      "DocumentName": "RunbookTutorialChildAutomation",
      "Targets": [
        {
          "Key": "tag:{{PatchGroupPrimaryKey}}",
```

```

        "Values": [
            "{{PatchGroupPrimaryValue}}"
        ]
    },
    "TargetParameterName": "InstanceId"
}
},
{
    "name": "patchSecondaryTargets",
    "action": "aws:executeAutomation",
    "onFailure": "Abort",
    "timeoutSeconds": 7200,
    "inputs": {
        "DocumentName": "RunbookTutorialChildAutomation",
        "Targets": [
            {
                "Key": "tag:{{PatchGroupSecondaryKey}}",
                "Values": [
                    "{{PatchGroupSecondaryValue}}"
                ]
            }
        ],
        "TargetParameterName": "InstanceId"
    }
}
]
}

```

- Emily reviews the completed parent runbook content and creates the runbook in the same AWS account and AWS Region as the target instances. Now, she is ready to test her runbooks to make sure the automation operates as desired before implementing them into her production environment. The following is the completed parent runbook content.

#### YAML

```

description: An example of an Automation runbook that patches groups of Amazon EC2
  instances in stages.
schemaVersion: '0.3'
assumeRole: '{{AutomationAssumeRole}}'
parameters:
  AutomationAssumeRole:
    type: String

```

```
description: '(Optional) The Amazon Resource Name (ARN) of the IAM role that
allows Automation to perform the actions on your behalf. If no role is specified,
Systems Manager Automation uses your IAM permissions to operate this runbook.'
default: ''

    }
  }
]
}

```

For more information about the automation actions used in this example, see the [Systems Manager Automation actions reference](#).

### Example 2: Scripted runbook

This example runbook addresses the following scenario. Emily is a Systems Engineer at AnyCompany Consultants, LLC. She previously created two runbooks that are used in a parent-child relationship to patch groups of Amazon Elastic Compute Cloud (Amazon EC2) instances that host

primary and secondary databases. Applications access these databases 24 hours a day, so one of the database instances must always be available.

Based on this requirement, she built a solution that patches the instances in stages using the `AWS-RunPatchBaseline` Systems Manager (SSM) document. By using this SSM document, her colleagues can review the associated patch compliance information after the patching operation completes.

The primary group of database instances are patched first, followed by the secondary group of database instances. Also, to avoid incurring additional costs by leaving instances running that were previously stopped, Emily made sure that the automation returned the patched instances to their original state before the patching occurred. Emily used tags that are associated with the primary and secondary groups of database instances to identify which instances should be patched in her desired order.

Her existing automated solution works, but she wants to improve her solution if possible. To help with the maintenance of the runbook content and to ease troubleshooting efforts, she would like to condense the automation into a single runbook and simplify the number of input parameters. Also, she would like to avoid creating multiple child automations.

After Emily reviews the available automation actions, she determines that she can improve her solution by using the `aws:executeScript` action to run her custom Python scripts. She now begins authoring the content for the runbook as follows:

1. First, she provides values for the schema and description of the runbook, and defines the input parameters for the parent runbook.

By using the `AutomationAssumeRole` parameter, Emily and her colleagues can use an existing IAM role that allows Automation to perform the actions in the runbook on their behalf. Unlike [Example 1](#), the `AutomationAssumeRole` parameter is now required rather than optional. Because this runbook includes `aws:executeScript` actions, an AWS Identity and Access Management (IAM) service role (or assume role) is always required. This requirement is necessary because some of the Python scripts specified for the actions call AWS API operations.

Emily uses the `PrimaryPatchGroupTag` and `SecondaryPatchGroupTag` parameters to specify the tags associated with the primary and secondary group of database instances that will be patched. To simplify the required input parameters, she decides to use `StringMap` parameters rather than using multiple `String` parameters as she used in the [Example 1](#) runbook. Optionally, the `Operation`, `RebootOption`, and `SnapshotId` parameters

can be used to provide values to document parameters for AWS-RunPatchBaseline. To prevent invalid values from being provided to those document parameters, she defines the `allowedValues` as needed.

## YAML

```
description: 'An example of an Automation runbook that patches groups of Amazon
  EC2 instances in stages.'
schemaVersion: '0.3'
assumeRole: '{{AutomationAssumeRole}}'
parameters:
  AutomationAssumeRole:
    type: String
    description: '(Required) The Amazon Resource Name (ARN) of the IAM role that
      allows Automation to perform the actions on your behalf. If no role is specified,
      Systems Manager Automation uses your IAM permissions to operate this runbook.'
  PrimaryPatchGroupTag:
    type: StringMap
    description: '(Required) The tag for the primary group of instances you want
      to patch. Specify a key-value pair. Example: {"key" : "value"}'
  SecondaryPatchGroupTag:
    type: StringMap
    description: '(Required) The tag for the secondary group of instances you want
      to patch. Specify a key-value pair. Example: {"key" : "value"}'
  SnapshotId:
    type: String
    description: '(Optional) The snapshot ID to use to retrieve a patch baseline
      snapshot.'
    default: ''
  RebootOption:
    type: String
    description: '(Optional) Reboot behavior after a patch Install operation. If
      you choose NoReboot and patches are installed, the instance is marked as non-
      compliant until a subsequent reboot and scan.'
    allowedValues:
      - NoReboot
      - RebootIfNeeded
    default: RebootIfNeeded
  Operation:
    type: String
    description: '(Optional) The update or configuration to perform on the
      instance. The system checks if patches specified in the patch baseline are
      installed on the instance. The install operation installs patches missing from
      the baseline.'
```

```

allowedValues:
  - Install
  - Scan
default: Install

```

## JSON

```

{

      "allowedValues": [
        "NoReboot",

```

```

        "RebootIfNeeded"
    ],
    "default": "RebootIfNeeded"
  },
  "Operation": {
    "type": "String",
    "description": "(Optional) The update or configuration to perform on
the instance. The system checks if patches specified in the patch baseline are
installed on the instance. The install operation installs patches missing from
the baseline.",
    "allowedValues": [
      "Install",
      "Scan"
    ],
    "default": "Install"
  }
}
},
},

```

2. With the top-level elements defined, Emily proceeds with authoring the actions that make up the `mainSteps` of the runbook. The first step gathers the IDs of all instances associated with the tag specified in the `PrimaryPatchGroupTag` parameter and outputs a `StringMap` parameter containing the instance ID and the current state of the instance. The output of this action is used in later actions.

Note that the `script` input parameter isn't supported for JSON runbooks. JSON runbooks must provide script content using the `attachment` input parameter.

## YAML

```

mainSteps:
  - name: getPrimaryInstanceState
    action: 'aws:executeScript'
    timeoutSeconds: 120
    onFailure: Abort
    inputs:
      Runtime: python3.7
      Handler: getInstanceStates
      InputPayload:
        primaryTag: '{{PrimaryPatchGroupTag}}'
      Script: |-
        def getInstanceStates(events, context):
          import boto3

```

```

#Initialize client
ec2 = boto3.client('ec2')
tag = events['primaryTag']
tagKey, tagValue = list(tag.items())[0]
instanceQuery = ec2.describe_instances(
Filters=[
    {
        "Name": "tag:" + tagKey,
        "Values": [tagValue]
    }
])
if not instanceQuery['Reservations']:
    noInstancesForTagString = "No instances found for specified tag."
    return({ 'noInstancesFound' : noInstancesForTagString })
else:
    queryResponse = instanceQuery['Reservations']
    originalInstanceStates = {}
    for results in queryResponse:
        instanceSet = results['Instances']
        for instance in instanceSet:
            instanceId = instance['InstanceId']
            originalInstanceStates[instanceId] = instance['State']
['Name']
        return originalInstanceStates
outputs:
- Name: originalInstanceStates
  Selector: $.Payload
  Type: StringMap
nextStep: verifyPrimaryInstancesRunning

```

## JSON

```

"mainSteps":[
    {
        "name":"getPrimaryInstanceState",
        "action":"aws:executeScript",
        "timeoutSeconds":120,
        "onFailure":"Abort",
        "inputs":{
            "Runtime":"python3.7",
            "Handler":"getInstanceStates",
            "InputPayload":{

```

```

        "primaryTag": "{{PrimaryPatchGroupTag}}"
    },
    "Script": "...",
  },
  "outputs": [
    {
      "Name": "originalInstanceStates",
      "Selector": "$.Payload",
      "Type": "StringMap"
    }
  ],
  "nextStep": "verifyPrimaryInstancesRunning"
},

```

- Emily uses the output from the previous action in another `aws:executeScript` action to verify all instances associated with the tag specified in the `PrimaryPatchGroupTag` parameter are in a running state.

If the instance state is already running or shutting-down, the script continues to loop through the remaining instances.

If the instance state is stopping, the script polls for the instance to reach the stopped state and starts the instance.

If the instance state is stopped, the script starts the instance.

## YAML

```

- name: verifyPrimaryInstancesRunning
  action: 'aws:executeScript'
  timeoutSeconds: 600
  onFailure: Abort
  inputs:
    Runtime: python3.7
    Handler: verifyInstancesRunning
    InputPayload:
      targetInstances: '{{getPrimaryInstanceState.originalInstanceStates}}'
  Script: |-
    def verifyInstancesRunning(events, context):
      import boto3

      #Initialize client
      ec2 = boto3.client('ec2')

```

```

instanceDict = events['targetInstances']
for instance in instanceDict:
    if instanceDict[instance] == 'stopped':
        print("The target instance " + instance + " is stopped. The
instance will now be started.")
        ec2.start_instances(
            InstanceIds=[instance]
        )
    elif instanceDict[instance] == 'stopping':
        print("The target instance " + instance + " is stopping. Polling
for instance to reach stopped state.")
        while instanceDict[instance] != 'stopped':
            poll = ec2.get_waiter('instance_stopped')
            poll.wait(
                InstanceIds=[instance]
            )
            ec2.start_instances(
                InstanceIds=[instance]
            )
        else:
            pass
nextStep: waitForPrimaryRunningInstances

```

## JSON

```

{
    "name": "verifyPrimaryInstancesRunning",
    "action": "aws:executeScript",
    "timeoutSeconds": 600,
    "onFailure": "Abort",
    "inputs": {
        "Runtime": "python3.7",
        "Handler": "verifyInstancesRunning",
        "InputPayload": {
            "targetInstances": "{getPrimaryInstanceState.originalInstanceStates}"
        },
        "Script": "..."
    },
    "nextStep": "waitForPrimaryRunningInstances"
},

```

4. Emily verifies that all instances associated with the tag specified in the `PrimaryPatchGroupTag` parameter were started or already in a `running` state. Then she uses another script to verify that all instances, including those that were started in the previous action, have reached the `running` state.

#### YAML

```
- name: waitForPrimaryRunningInstances
  action: 'aws:executeScript'
  timeoutSeconds: 300
  onFailure: Abort
  inputs:
    Runtime: python3.7
    Handler: waitForRunningInstances
    InputPayload:
      targetInstances: '{{getPrimaryInstanceState.originalInstanceStates}}'
  Script: |-
    def waitForRunningInstances(events, context):
        import boto3

        #Initialize client
        ec2 = boto3.client('ec2')
        instanceDict = events['targetInstances']
        for instance in instanceDict:
            poll = ec2.get_waiter('instance_running')
            poll.wait(
                InstanceIds=[instance]
            )
    nextStep: returnPrimaryTagKey
```

#### JSON

```
{
  "name": "waitForPrimaryRunningInstances",
  "action": "aws:executeScript",
  "timeoutSeconds": 300,
  "onFailure": "Abort",
  "inputs": {
    "Runtime": "python3.7",
    "Handler": "waitForRunningInstances",
    "InputPayload": {
      "targetInstances": "{{getPrimaryInstanceState.originalInstanceStates}}"
    }
  }
}
```

```

    },
    "Script": "...",
  },
  "nextStep": "returnPrimaryTagKey"
},

```

5. Emily uses two more scripts to return individual `String` values of the key and value of the tag specified in the `PrimaryPatchGroupTag` parameter. The values returned by these actions allows her to provide values directly to the `Targets` parameter for the `AWS-RunPatchBaseline` document. The automation then proceeds with patching the instance with the `AWS-RunPatchBaseline` document using the `aws:runCommand` action.

## YAML

```

- name: returnPrimaryTagKey
  action: 'aws:executeScript'
  timeoutSeconds: 120
  onFailure: Abort
  inputs:
    Runtime: python3.7
    Handler: returnTagValues
    InputPayload:
      primaryTag: '{{PrimaryPatchGroupTag}}'
    Script: |-
      def returnTagValues(events, context):
        tag = events['primaryTag']
        tagKey = list(tag)[0]
        stringKey = "tag:" + tagKey
        return {'tagKey' : stringKey}
  outputs:
    - Name: Payload
      Selector: $.Payload
      Type: StringMap
    - Name: primaryPatchGroupKey
      Selector: $.Payload.tagKey
      Type: String
  nextStep: returnPrimaryTagValue
- name: returnPrimaryTagValue
  action: 'aws:executeScript'
  timeoutSeconds: 120
  onFailure: Abort
  inputs:
    Runtime: python3.7

```

```

Handler: returnTagValues
InputPayload:
  primaryTag: '{{PrimaryPatchGroupTag}}'
Script: |-
  def returnTagValues(events,context):
    tag = events['primaryTag']
    tagKey = list(tag)[0]
    tagValue = tag[tagKey]
    return {'tagValue' : tagValue}
outputs:
  - Name: Payload
    Selector: $.Payload
    Type: StringMap
  - Name: primaryPatchGroupValue
    Selector: $.Payload.tagValue
    Type: String
nextStep: patchPrimaryInstances
- name: patchPrimaryInstances
  action: 'aws:runCommand'
  onFailure: Abort
  timeoutSeconds: 7200
  inputs:
    DocumentName: AWS-RunPatchBaseline
    Parameters:
      SnapshotId: '{{SnapshotId}}'
      RebootOption: '{{RebootOption}}'
      Operation: '{{Operation}}'
    Targets:
      - Key: '{{returnPrimaryTagKey.primaryPatchGroupKey}}'
        Values:
          - '{{returnPrimaryTagValue.primaryPatchGroupValue}}'
    MaxConcurrency: 10%
    MaxErrors: 10%
  nextStep: returnPrimaryToOriginalState

```

## JSON

```

{

      ]
    }
  ],
  "MaxConcurrency": "10%",
  "MaxErrors": "10%"
},
"nextStep": "returnPrimaryToOriginalState"
},

```

- After the patching operation completes, Emily wants the automation to return the target instances associated with the tag specified in the `PrimaryPatchGroupTag` parameter to the same state they were before the automation started. She does this by again using the output from the first action in a script. Based on the original state of the target instance, if the instance was previously in any state other than `running`, the instance is stopped. Otherwise, if the instance state is `running`, the script continues to loop through the remaining instances.

#### YAML

```

- name: returnPrimaryToOriginalState
  action: 'aws:executeScript'
  timeoutSeconds: 600
  onFailure: Abort

```

```

inputs:
  Runtime: python3.7
  Handler: returnToOriginalState
  InputPayload:
    targetInstances: '{{getPrimaryInstanceState.originalInstanceStates}}'
  Script: |-
    def returnToOriginalState(events,context):
        import boto3

        #Initialize client
        ec2 = boto3.client('ec2')
        instanceDict = events['targetInstances']
        for instance in instanceDict:
            if instanceDict[instance] == 'stopped' or instanceDict[instance] ==
'stopping':
                ec2.stop_instances(
                    InstanceIds=[instance]
                )
            else:
                pass
    nextStep: getSecondaryInstanceState

```

## JSON

```

{
    "name": "returnPrimaryToOriginalState",
    "action": "aws:executeScript",
    "timeoutSeconds": 600,
    "onFailure": "Abort",
    "inputs": {
        "Runtime": "python3.7",
        "Handler": "returnToOriginalState",
        "InputPayload": {
            "targetInstances": "{{getPrimaryInstanceState.originalInstanceStates}}"
        },
        "Script": "...",
    },
    "nextStep": "getSecondaryInstanceState"
},

```

7. The patching operation is completed for the instances associated with the tag specified in the PrimaryPatchGroupTag parameter. Now Emily duplicates all of the previous actions

in her runbook content to target the instances associated with the tag specified in the `SecondaryPatchGroupTag` parameter.

## YAML

```
- name: getSecondaryInstanceState
  action: 'aws:executeScript'
  timeoutSeconds: 120
  onFailure: Abort
  inputs:
    Runtime: python3.7
    Handler: getInstanceStates
    InputPayload:
      secondaryTag: '{{SecondaryPatchGroupTag}}'
  Script: |-
    def getInstanceStates(events,context):
        import boto3

        #Initialize client
        ec2 = boto3.client('ec2')
        tag = events['secondaryTag']
        tagKey, tagValue = list(tag.items())[0]
        instanceQuery = ec2.describe_instances(
            Filters=[
                {
                    "Name": "tag:" + tagKey,
                    "Values": [tagValue]
                }
            ]
        )
        if not instanceQuery['Reservations']:
            noInstancesForTagString = "No instances found for specified tag."
            return({ 'noInstancesFound' : noInstancesForTagString })
        else:
            queryResponse = instanceQuery['Reservations']
            originalInstanceStates = {}
            for results in queryResponse:
                instanceSet = results['Instances']
                for instance in instanceSet:
                    instanceId = instance['InstanceId']
                    originalInstanceStates[instanceId] = instance['State']

    ['Name']

        return originalInstanceStates

  outputs:
    - Name: originalInstanceStates
```

```
    Selector: $.Payload
    Type: StringMap
  nextStep: verifySecondaryInstancesRunning
- name: verifySecondaryInstancesRunning
  action: 'aws:executeScript'
  timeoutSeconds: 600
  onFailure: Abort
  inputs:
    Runtime: python3.7
    Handler: verifyInstancesRunning
    InputPayload:
      targetInstances: '{{getSecondaryInstanceState.originalInstanceStates}}'
  Script: |-
    def verifyInstancesRunning(events,context):

- Emily reviews the completed scripted runbook content and creates the runbook in the same AWS account and AWS Region as the target instances. Now she's ready to test her runbook

to make sure the automation operates as desired before implementing it into her production environment. The following is the completed scripted runbook content.

## YAML

```
description: An example of an Automation runbook that patches groups of Amazon EC2
  instances in stages.
schemaVersion: '0.3'
assumeRole: '{{AutomationAssumeRole}}'
parameters:
  AutomationAssumeRole:
    type: String
    description: '(Required) The Amazon Resource Name (ARN) of the IAM role that
  allows Automation to perform the actions on your behalf. If no role is specified,
  Systems Manager Automation uses your IAM permissions to operate this runbook.'
  PrimaryPatchGroupTag:
    type: StringMap
    description: '(Required) The tag for the primary group of instances you want
  to patch. Specify a key-value pair. Example: {"key" : "value"}'
  SecondaryPatchGroupTag:
    type: StringMap
    description: '(Required) The tag for the secondary group of instances you want
  to patch. Specify a key-value pair. Example: {"key" : "value"}'
  SnapshotId:
    type: String
    description: '(Optional) The snapshot ID to use to retrieve a patch baseline
  snapshot.'
    default: ''
  RebootOption:
    type: String
    description: '(Optional) Reboot behavior after a patch Install operation. If
  you choose NoReboot and patches are installed, the instance is marked as non-
  compliant until a subsequent reboot and scan.'
    allowedValues:
      - NoReboot
      - RebootIfNeeded
    default: RebootIfNeeded
  Operation:
    type: String
    description: '(Optional) The update or configuration to perform on the
  instance. The system checks if patches specified in the patch baseline are
  installed on the instance. The install operation installs patches missing from
  the baseline.'
    allowedValues:
```

```

For more information about the automation actions used in this example, see the [Systems Manager Automation actions reference](#).

## Additional runbook examples

The following example runbook demonstrate how you can use AWS Systems Manager automation actions to automate common deployment, troubleshooting, and maintenance tasks.

### Note

The example runbooks in this section are provided to demonstrate how you can create custom runbooks to support your specific operational needs. These runbooks aren't meant for use in production environments as is. However, you can customize them for your own use.

## Examples

- [Deploy VPC architecture and Microsoft Active Directory domain controllers](#)
- [Restore a root volume from the latest snapshot](#)
- [Create an AMI and cross-Region copy](#)

### Deploy VPC architecture and Microsoft Active Directory domain controllers

To increase efficiency and standardize common tasks, you might choose to automate deployments. This is useful if you regularly deploy the same architecture across multiple accounts and AWS Regions. Automating architecture deployments can also reduce the potential for human error that can occur when deploying architecture manually. AWS Systems Manager Automation actions can help you accomplish this. Automation is a capability of AWS Systems Manager.

The following example AWS Systems Manager runbook performs these actions:

- Retrieves the latest Windows Server 2016 Amazon Machine Image (AMI) using Systems Manager Parameter Store to use when launching the EC2 instances that will be configured as domain controllers. Parameter Store is a capability of AWS Systems Manager.
- Uses the `aws:executeAwsApi` automation action to call several AWS API operations to create the VPC architecture. The domain controller instances are launched in private subnets, and connect to the internet using a NAT gateway. This allows the SSM Agent on the instances to access the requisite Systems Manager endpoints.
- Uses the `aws:waitForAwsResourceProperty` automation action to confirm the instances launched by the previous action are `Online` for AWS Systems Manager.

- Uses the `aws:runCommand` automation action to configure the instances launched as Microsoft Active Directory domain controllers.

## Restore a root volume from the latest snapshot

The operating system on a root volume can become corrupted for various reasons. For example, following a patching operation, instances might fail to boot successfully due to a corrupted kernel or registry. Automating common troubleshooting tasks, like restoring a root volume from the latest snapshot taken before the patching operation, can reduce downtime and expedite your troubleshooting efforts. AWS Systems Manager Automation actions can help you accomplish this. Automation is a capability of AWS Systems Manager.

The following example AWS Systems Manager runbook performs these actions:

- Uses the `aws:executeAwsApi` automation action to retrieve details from the root volume of the instance.
- Uses the `aws:executeScript` automation action to retrieve the latest snapshot for the root volume.
- Uses the `aws:branch` automation action to continue the automation if a snapshot is found for the root volume.

            "sha256": "sampleETagValue"
        }
    }
}
}
```

## Create an AMI and cross-Region copy

Creating an Amazon Machine Image (AMI) of an instance is a common process used in backup and recovery. You might also choose to copy an AMI to another AWS Region as part of a disaster recovery architecture. Automating common maintenance tasks can reduce downtime if an issue requires failover. AWS Systems Manager Automation actions can help you accomplish this. Automation is a capability of AWS Systems Manager.

The following example AWS Systems Manager runbook performs these actions:

- Uses the `aws:executeAwsApi` automation action to create an AMI.
- Uses the `aws:waitForAwsResourceProperty` automation action to confirm the availability of the AMI.
- Uses the `aws:executeScript` automation action to copy the AMI to the destination Region.

## YAML

```
---
description: Custom Automation Backup and Recovery Example
schemaVersion: '0.3'
```

```
assumeRole: "{{ AutomationAssumeRole }}"
parameters:
  AutomationAssumeRole:
    type: String
    description: "(Required) The ARN of the role that allows Automation to
perform
the actions on your behalf. If no role is specified, Systems Manager
Automation
uses your IAM permissions to use this runbook."
    default: ''
  InstanceId:
    type: String
    description: "(Required) The ID of the EC2 instance."
    default: ''
mainSteps:
- name: createImage
  action: aws:executeAwsApi
  onFailure: Abort
  inputs:
    Service: ec2
    Api: CreateImage
    InstanceId: "{{ InstanceId }}"
    Name: "Automation Image for {{ InstanceId }}"
    NoReboot: false
  outputs:
    - Name: newImageId
      Selector: "$.ImageId"
      Type: String
  nextStep: verifyImageAvailability
- name: verifyImageAvailability
  action: aws:waitForAwsResourceProperty
  timeoutSeconds: 600
  inputs:
    Service: ec2
    Api: DescribeImages
    ImageIds:
      - "{{ createImage.newImageId }}"
    PropertySelector: "$.Images[0].State"
    DesiredValues:
      - available
  nextStep: copyImage
- name: copyImage
  action: aws:executeScript
  timeoutSeconds: 45
```

```

onFailure: Abort
inputs:
  Runtime: python3.8
  Handler: crossRegionImageCopy
  InputPayload:
    newImageId : "{{ createImage.newImageId }}"
  Script: |-
    def crossRegionImageCopy(events,context):
      import boto3

      #Initialize client
      ec2 = boto3.client('ec2', region_name='us-east-1')
      newImageId = events['newImageId']

      ec2.copy_image(
        Name='DR Copy for ' + newImageId,
        SourceImageId=newImageId,
        SourceRegion='us-west-2'
      )

```

## JSON

```

    }
}
}

```

## Creating input parameters that populate AWS resources

Automation, a capability of Systems Manager, populates AWS resources in the AWS Management Console that match the resource type you define for an input parameter. Resources in your AWS account that match the resource type are displayed in a dropdown list for you to choose. You can define input parameter types for Amazon Elastic Compute Cloud (Amazon EC2) instances, Amazon Simple Storage Service (Amazon S3) buckets, and AWS Identity and Access Management (IAM) roles. The supported type definitions and the regular expressions used to locate matching resources are as follows:

- `AWS::EC2::Instance::Id - ^m?i-([a-z0-9]{8}|[a-z0-9]{17})$`
- `List<AWS::EC2::Instance::Id> - ^m?i-([a-z0-9]{8}|[a-z0-9]{17})$`
- `AWS::S3::Bucket::Name - ^[0-9a-z][a-z0-9\\-\\.]{3,63}$`
- `List<AWS::S3::Bucket::Name> - ^[0-9a-z][a-z0-9\\-\\.]{3,63}$`
- `AWS::IAM::Role::Arn - ^arn:(aws|aws-cn|aws-us-gov|aws-iso|aws-iso-b):iam::[0-9]{12}:role/.*$`
- `List<AWS::IAM::Role::Arn> - ^arn:(aws|aws-cn|aws-us-gov|aws-iso|aws-iso-b):iam::[0-9]{12}:role/.*$`

The following is an example of input parameter types defined in runbook content.

## YAML

```

description: Enables encryption on an Amazon S3 bucket
schemaVersion: '0.3'
assumeRole: '{{ AutomationAssumeRole }}'
parameters:
  BucketName:
    type: 'AWS::S3::Bucket::Name'
    description: (Required) The name of the Amazon S3 bucket you want to encrypt.
  SSEAlgorithm:
    type: String
    description: (Optional) The server-side encryption algorithm to use for the
default encryption.
    default: AES256
  AutomationAssumeRole:
    type: 'AWS::IAM::Role::Arn'
    description: (Optional) The Amazon Resource Name (ARN) of the role that allows
Automation to perform the actions on your behalf.
    default: ''
mainSteps:
- name: enableBucketEncryption
  action: 'aws:executeAwsApi'
  inputs:
    Service: s3
    Api: PutBucketEncryption
    Bucket: '{{BucketName}}'
    ServerSideEncryptionConfiguration:
      Rules:
        - ApplyServerSideEncryptionByDefault:
            SSEAlgorithm: '{{SSEAlgorithm}}'
  isEnd: true

```

## JSON

```

{
  "description": "Enables encryption on an Amazon S3 bucket",
  "schemaVersion": "0.3",
  "assumeRole": "{{ AutomationAssumeRole }}",
  "parameters": {
    "BucketName": {
      "type": "AWS::S3::Bucket::Name",
      "description": "(Required) The name of the Amazon S3 bucket you want to
encrypt."
    }
  }
}

```

```

    },
    "SSEAlgorithm": {
      "type": "String",

        }
      },
      "isEnd": true
    }
  ]
}

```

## Using Document Builder to create runbooks

If the AWS Systems Manager public runbooks don't support all the actions you want to perform on your AWS resources, you can create your own runbooks. To create a custom runbook, you can manually create a local YAML or JSON format file with the appropriate automation actions.

Alternatively, you can use Document Builder in the Systems Manager Automation console to build a custom runbook.

Using Document Builder, you can add automation actions to your custom runbook and provide the required parameters without having to use JSON or YAML syntax. After you add steps and create the runbook, the system converts the actions you've added into the YAML format that Systems Manager can use to run automation.

Runbooks support the use of Markdown, a markup language, which allows you to add wiki-style descriptions to runbooks and individual steps within the runbook. For more information about using Markdown, see [Using Markdown in AWS](#).

## Create a runbook using Document Builder

### Before you begin

We recommend that you read about the different actions that you can use within a runbook. For more information, see [Systems Manager Automation actions reference](#).

### To create a runbook using Document Builder

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
  2. In the navigation pane, choose **Documents**.
  3. Choose **Create automation**.
  4. For **Name**, enter a descriptive name for the runbook.
  5. For **Document description**, provide the markdown style description for the runbook. You can provide instructions for using the runbook, numbered steps, or any other type of information to describe the runbook. Refer to the default text for information about formatting your content.
- 
- #### Tip
- Toggle between **Hide preview** and **Show preview** to see what your description content looks like as you compose.
6. (Optional) For **Assume role**, enter the name or ARN of a service role to perform actions on your behalf. If you don't specify a role, Automation uses the access permissions of the user who runs the automation.

**⚠ Important**

For runbooks not owned by Amazon that use the `aws:executeScript` action, a role must be specified. For information, see [Permissions for using runbooks](#).

7. (Optional) For **Outputs**, enter any outputs for the automation of this runbook to make available for other processes.

For example, if your runbook creates a new AMI, you might specify ["CreateImage.ImageId"], and then use this output to create new instances in a subsequent automation.

8. (Optional) Expand the **Input parameters** section and do the following.
  1. For **Parameter name**, enter a descriptive name for the runbook parameter you're creating.
  2. For **Type**, choose a type for the parameter, such as `String` or `MapList`.
  3. For **Required**, do one of the following:
    - Choose **Yes** if a value for this runbook parameter must be supplied at runtime.
    - Choose **No** if the parameter isn't required, and (optional) enter a default parameter value in **Default value**.
  4. For **Description**, enter a description for the runbook parameter.

**ℹ Note**

To add more runbook parameters, choose **Add a parameter**. To remove a runbook parameter, choose the **X (Remove)** button.

9. (Optional) Expand the **Target type** section and choose a target type to define the kinds of resources the automation can run on. For example, to use a runbook on EC2 instances, choose `/AWS::EC2::Instance`.

**ℹ Note**

If you specify a value of `/`, the runbook can run on all types of resources. For a list of valid resource types, see [AWS Resource Types Reference](#) in the *AWS CloudFormation User Guide*.

10. (Optional) Expand the **Document tags** section and enter one or more tag key-value pairs to apply to the runbook. Tags make it easier to identify, organize, and search for resources.
11. In the **Step 1** section, provide the following information.

- For **Step name**, enter a descriptive name for the first step of the automation.
- For **Action type**, select the action type to use for this step.

For a list and information about the available action types, see [Systems Manager Automation actions reference](#).

- For **Description**, enter a description for the automation step. You can use Markdown to format your text.
- Depending on the **Action type** selected, enter the required inputs for the action type in the **Step inputs** section. For example, if you selected the action `aws:approve`, you must specify a value for the `Approver`s property.

For information about the step input fields, see the entry in [Systems Manager Automation actions reference](#) for the action type you selected. For example: [aws:executeStateMachine – Run an AWS Step Functions state machine](#).

- (Optional) For **Additional inputs**, provide any additional input values needed for your runbook. The available input types depend on the action type you selected for the step. (Note that some action types require input values.)

 **Note**

To add more inputs, choose **Add optional input**. To remove an input, choose the **X (Remove)** button.

- (Optional) For **Outputs**, enter any outputs for this step to make available for other processes.

 **Note**

**Outputs** isn't available for all action types.

- (Optional) Expand the **Common properties** section and specify properties for the actions that are common to all automation actions. For example, for **Timeout seconds**, you can provide a value in seconds to specify how long the step can run before it's stopped.

For more information, see [Properties shared by all actions](#).

**Note**

To add more steps, select **Add step** and repeat the procedure for creating a step. To remove a step, choose **Remove step**.

12. Choose **Create automation** to save the runbook.

## Create a runbook that runs scripts

The following procedure shows how to use Document Builder in the AWS Systems Manager Automation console to create a custom runbook that runs a script.

The first step of the runbook you create runs a script to launch an Amazon Elastic Compute Cloud (Amazon EC2) instance. The second step runs another script to monitor for the instance status check to change to ok. Then, an overall status of Success is reported for the automation.

### Before you begin

Make sure you have completed the following steps:

- Verify that you have administrator privileges, or that you have been granted the appropriate permissions to access Systems Manager in AWS Identity and Access Management (IAM).

For information, see [Verifying user access for runbooks](#).

- Verify that you have an IAM service role for Automation (also known as an *assume role*) in your AWS account. The role is required because this walkthrough uses the `aws:executeScript` action.

For information about creating this role, see [Configuring a service role \(assume role\) access for automations](#).

For information about the IAM service role requirement for running `aws:executeScript`, see [Permissions for using runbooks](#).

- Verify that you have permission to launch EC2 instances.

For information, see [IAM and Amazon EC2](#) in the *Amazon EC2 User Guide*.

## To create a custom runbook that runs scripts using Document Builder

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Documents**.
3. Choose **Create automation**.
4. For **Name**, type this descriptive name for the runbook: **LaunchInstanceAndCheckStatus**.
5. (Optional) For **Document description**, replace the default text with a description for this runbook, using Markdown. The following is an example.

```
##Title: LaunchInstanceAndCheckState
-----
**Purpose**: This runbook first launches an EC2 instance using the AMI
ID provided in the parameter ``imageId``. The second step of this runbook
continuously checks the instance status check value for the launched instance
until the status ``ok`` is returned.

##Parameters:
-----
Name | Type | Description | Default Value
-----|-----|-----|-----
assumeRole | String | (Optional) The ARN of the role that allows Automation to
perform the actions on your behalf. | -
imageId | String | (Optional) The AMI ID to use for launching the instance.
The default value uses the latest Amazon Linux AMI ID available. | {{ ssm:/aws/
service/ami-amazon-linux-latest/amzn-ami-hvm-x86_64-gp2 }}
```

6. For **Assume role**, enter the ARN of the IAM service role for Automation (Assume role) for the automation, in the format **arn:aws:iam::111122223333:role/AutomationServiceRole**. Substitute your AWS account ID for 111122223333.

The role you specify is used to provide the permissions needed to start the automation.

### Important

For runbooks not owned by Amazon that use the `aws:executeScript` action, a role must be specified. For information, see [Permissions for using runbooks](#).

7. Expand **Input parameters** and do the following.

1. For **Parameter name**, enter **imageId**.
2. For **Type**, choose **String**.
3. For **Required**, choose No.
4. For **Default value**, enter the following.

```
{{ ssm:/aws/service/ami-amazon-linux-latest/amzn-ami-hvm-x86_64-gp2 }}
```

 **Note**

This value launches an Amazon EC2 instance using the latest Amazon Linux 1 Amazon Machine Image (AMI) ID. If you want to use a different AMI, replace the value with your AMI ID.

5. For **Description**, enter the following.

(Optional) The AMI ID to use for launching the instance. The default value uses the latest released Amazon Linux AMI ID.

8. Choose **Add a parameter** to create the second parameter, **tagValue**, and enter the following.

1. For **Parameter name**, enter **tagValue**.
2. For **Type**, choose **String**.
3. For **Required**, choose No.
4. For **Default value**, enter **LaunchedBySsmAutomation**. This adds the tag key-pair value `Name:LaunchedBySsmAutomation` to the instance.
5. For **Description**, enter the following.

(Optional) The tag value to add to the instance. The default value is `LaunchedBySsmAutomation`.

9. Choose **Add a parameter** to create the third parameter, **instanceType**, and enter the following information.

1. For **Parameter name**, enter **instanceType**.
2. For **Type**, choose **String**.
3. For **Required**, choose No.

4. For **Default value**, enter **t2.micro**.
5. For **Parameter description**, enter the following.

(Optional) The instance type to use for the instance. The default value is t2.micro.

10. Expand **Target type** and choose **"/"**.
11. (Optional) Expand **Document tags** to apply resource tags to your runbook. For **Tag key**, enter **Purpose**, and for **Tag value**, enter **LaunchInstanceAndCheckState**.
12. In the **Step 1** section, complete the following steps.
  1. For **Step name**, enter this descriptive step name for the first step of the automation: **LaunchEc2Instance**.
  2. For **Action type**, choose **Run a script (aws:executeScript)**.
  3. For **Description**, enter a description for the automation step, such as the following.

**\*\*About This Step\*\***

This step first launches an EC2 instance using the `aws:executeScript` action and the provided script.

4. Expand **Inputs**.
5. For **Runtime**, choose the runtime language to use to run the provided script.
6. For **Handler**, enter **launch\_instance**. This is the function name declared in the following script.

 **Note**

This is not required for PowerShell.

7. For **Script**, replace the default contents with the following. Be sure to match the script with the corresponding runtime value.

Python

```
def launch_instance(events, context):
    import boto3
    ec2 = boto3.client('ec2')
```

```
image_id = events['image_id']
tag_value = events['tag_value']
instance_type = events['instance_type']

tag_config = {'ResourceType': 'instance', 'Tags': [{'Key': 'Name',
'Value': tag_value}]}

res = ec2.run_instances(ImageId=image_id, InstanceType=instance_type,
MaxCount=1, MinCount=1, TagSpecifications=[tag_config])

instance_id = res['Instances'][0]['InstanceId']

print('[INFO] 1 EC2 instance is successfully launched', instance_id)

return { 'InstanceId' : instance_id }
```

## PowerShell

```
Install-Module AWS.Tools.EC2 -Force
Import-Module AWS.Tools.EC2

$payload = $env:InputPayload | ConvertFrom-Json

$imageid = $payload.image_id

>tagvalue = $payload.tag_value

$instanceType = $payload.instance_type

$type = New-Object Amazon.EC2.InstanceType -ArgumentList $instanceType

$resource = New-Object Amazon.EC2.ResourceType -ArgumentList 'instance'

>tag = @{Key='Name';Value=$tagValue}

>tagSpecs = New-Object Amazon.EC2.Model.TagSpecification

>tagSpecs.ResourceType = $resource

>tagSpecs.Tags.Add($tag)

$res = New-EC2Instance -ImageId $imageId -MinCount 1 -MaxCount 1 -
InstanceType $type -TagSpecification $tagSpecs
```

```
return @{'InstanceId'=$res.Instances.InstanceId}
```

8. Expand **Additional inputs**.

9. For **Input name**, choose **InputPayload**. For **Input value**, enter the following YAML data.

```
image_id: "{{ imageId }}"
tag_value: "{{ tagValue }}"
instance_type: "{{ instanceType }}"
```

13. Expand **Outputs** and do the following:

- For **Name**, enter **payload**.
- For **Selector**, enter **\$.Payload**.
- For **Type**, choose **StringMap**.

14. Choose **Add step** to add a second step to the runbook. The second step queries the status of the instance launched in Step 1 and waits until the status returned is ok.

15. In the **Step 2** section, do the following.

1. For **Step name**, enter this descriptive name for the second step of the automation:  
**WaitForInstanceStatusOk**.
2. For **Action type**, choose **Run a script (aws:executeScript)**.
3. For **Description**, enter a description for the automation step, such as the following.

**\*\*About This Step\*\***

The script continuously polls the instance status check value for the instance launched in Step 1 until the ``ok`` status is returned.

4. For **Runtime**, choose the runtime language to be used for executing the provided script.
5. For **Handler**, enter **poll\_instance**. This is the function name declared in the following script.

 **Note**

This is not required for PowerShell.

6. For **Script**, replace the default contents with the following. Be sure to match the script with the corresponding runtime value.

### Python

```
def poll_instance(events, context):
    import boto3
    import time

    ec2 = boto3.client('ec2')

    instance_id = events['InstanceId']

    print('[INFO] Waiting for instance status check to report ok',
instance_id)

    instance_status = "null"

    while True:
        res = ec2.describe_instance_status(InstanceIds=[instance_id])

        if len(res['InstanceStatuses']) == 0:
            print("Instance status information is not available yet")
            time.sleep(5)
            continue

        instance_status = res['InstanceStatuses'][0]['InstanceStatus']
['Status']

        print('[INFO] Polling to get status of the instance', instance_status)

        if instance_status == 'ok':
            break

        time.sleep(10)

    return {'Status': instance_status, 'InstanceId': instance_id}
```

### PowerShell

```
Install-Module AWS.Tools.EC2 -Force
```

```
$inputPayload = $env:InputPayload | ConvertFrom-Json

$instanceId = $inputPayload.payload.InstanceId

$status = Get-EC2InstanceStatus -InstanceId $instanceId

while ($status.Status.Status -ne 'ok'){
    Write-Host 'Polling get status of the instance', $instanceId

    Start-Sleep -Seconds 5

    $status = Get-EC2InstanceStatus -InstanceId $instanceId
}

return @{Status = $status.Status.Status; InstanceId = $instanceId}
```

7. Expand **Additional inputs**.

8. For **Input name**, choose **InputPayload**. For **Input value**, enter the following:

```
{{ LaunchEc2Instance.payload }}
```

16. Choose **Create automation** to save the runbook.

## Using scripts in runbooks

Automation runbooks support running scripts as part of the automation. Automation is a capability of AWS Systems Manager. By using runbooks, you can run scripts directly in AWS without creating a separate compute environment to run your scripts. Because runbooks can run script steps along with other automation step types, such as approvals, you can manually intervene in critical or ambiguous situations. You can send the output from `aws:executeScript` actions in your runbooks to Amazon CloudWatch Logs. For more information, see [Logging Automation action output with CloudWatch Logs](#).

## Permissions for using runbooks

To use a runbook, Systems Manager must use the permissions of an AWS Identity and Access Management (IAM) role. The method that Automation uses to determine which role's permissions to use depends on a few factors, and whether a step uses the `aws:executeScript` action.

For runbooks that don't use `aws:executeScript`, Automation uses one of two sources of permissions:

- The permissions of an IAM service role, or Assume role, that is specified in the runbook or passed in as a parameter.
- If no IAM service role is specified, the permissions of the user who started the automation.

When a step in a runbook includes the `aws:executeScript` action, however, an IAM service role (Assume role) is always required if the Python or PowerShell script specified for the action is calling any AWS API operations. Automation checks for this role in the following order:

- The permissions of an IAM service role, or Assume role, that is specified in the runbook or passed in as a parameter.
- If no role is found, Automation attempts to run the Python or PowerShell script specified for `aws:executeScript` without any permissions. If the script is calling an AWS API operation (for example the Amazon EC2 `CreateImage` operation), or attempting to act on an AWS resource (such as an EC2 instance), the step containing the script fails, and Systems Manager returns an error message reporting the failure.

## Adding scripts to runbooks

You can add scripts to your runbooks by including the script inline as part of a step in the runbook. You can also attach scripts to the runbook by uploading the scripts from your local machine or by specifying an Amazon Simple Storage Service (Amazon S3) bucket where the scripts are located. After a step that runs a script is complete, the output of the script is available as a JSON object, which you can then use as input for subsequent steps in your runbook. For more information about the `aws:executeScript` action and how to use attachments for scripts, see [aws:executeScript – Run a script](#).

## Script constraints for runbooks

Runbooks enforce a limit of five file attachments. Scripts can either be in the form of a Python script (.py), a PowerShell Core script (.ps1), or attached as contents within a .zip file.

## Using conditional statements in runbooks

By default, the steps that you define in the `mainSteps` section of a runbook run in sequential order. After one action is completed, the next action specified in the `mainSteps` section begins. Furthermore, if an action fails to run, the entire automation fails (by default). You can use the `aws:branch` automation action and the runbook options described in this section to create automations that perform *conditional branching*. This means that you can create automations that

jump to a different step after evaluating different choices or that dynamically respond to changes when a step is complete. Here is a list of options that you can use to create dynamic automations:

- **aws:branch:** This automation action allows you to create a dynamic automation that evaluates multiple choices in a single step and then jumps to a different step in the runbook based on the results of that evaluation.
- **nextStep:** This option specifies which step in an automation to process next after successfully completing a step.
- **isEnd:** This option stops an automation at the end of a specific step. The default value for this option is false.
- **isCritical:** This option designates a step as critical for the successful completion of the automation. If a step with this designation fails, then Automation reports the final status of the automation as Failed. The default value for this option is true.
- **onFailure:** This option indicates whether the automation should stop, continue, or go to a different step on failure. The default value for this option is abort.

The following section describes the `aws:branch` automation action. For more information about the `nextStep`, `isEnd`, `isCritical`, and `onFailure` options, see [Example aws:branch runbooks](#).

### Working with the `aws:branch` action

The `aws:branch` action offers the most dynamic conditional branching options for automations. As noted earlier, this action allows your automation to evaluate multiple conditions in a single step and then jump to a new step based on the results of that evaluation. The `aws:branch` action functions like an IF-ELIF-ELSE statement in programming.

Here is a YAML example of an `aws:branch` step.

```
- name: ChooseOSforCommands
  action: aws:branch
  inputs:
    Choices:
      - NextStep: runPowerShellCommand
        Variable: "{{GetInstance.platform}}"
        StringEquals: Windows
      - NextStep: runShellCommand
        Variable: "{{GetInstance.platform}}"
```

```
StringEquals: Linux
Default:
  PostProcessing
```

When you specify the `aws:branch` action for a step, you specify `Choices` that the automation must evaluate. The automation can evaluate `Choices` based on the value of a parameter that you specified in the `Parameters` section of the runbook. The automation can also evaluate `Choices` based on output from a previous step.

The automation evaluates each choice by using a Boolean expression. If the evaluation determines that the first choice is `true`, then the automation jumps to the step designated for that choice. If the evaluation determines that the first choice is `false`, then the automation evaluates the next choice. If your step includes three or more `Choices`, then the automation evaluates each choice in sequential order until it evaluates a choice that is `true`. The automation then jumps to the designated step for the `true` choice.

If none of the `Choices` are `true`, the automation checks to see if the step contains a `Default` value. A `Default` value defines a step that the automation should jump to if none of the choices are `true`. If no `Default` value is specified for the step, then the automation processes the next step in the runbook.

Here is an `aws:branch` step in YAML named **chooseOSfromParameter**. The step includes two `Choices`: (`NextStep: runWindowsCommand`) and (`NextStep: runLinuxCommand`). The automation evaluates these `Choices` to determine which command to run for the appropriate operating system. The `Variable` for each choice uses `{{OSName}}`, which is a parameter that the runbook author defined in the `Parameters` section of the runbook.

```
mainSteps:
- name: chooseOSfromParameter
  action: aws:branch
  inputs:
    Choices:
      - NextStep: runWindowsCommand
        Variable: "{{OSName}}"
        StringEquals: Windows
      - NextStep: runLinuxCommand
        Variable: "{{OSName}}"
        StringEquals: Linux
```

Here is an `aws:branch` step in YAML named **chooseOSfromOutput**. The step includes two `Choices`: (`NextStep: runPowerShellCommand`) and (`NextStep: runShellCommand`). The automation evaluates these `Choices` to determine which command to run for the appropriate operating system. The `Variable` for each choice uses `{{GetInstance.platform}}`, which is the output from an earlier step in the runbook. This example also includes an option called `Default`. If the automation evaluates both `Choices`, and neither choice is `true`, then the automation jumps to a step called `PostProcessing`.

```
mainSteps:
- name: chooseOSfromOutput
  action: aws:branch
  inputs:
    Choices:
      - NextStep: runPowerShellCommand
        Variable: "{{GetInstance.platform}}"
        StringEquals: Windows
      - NextStep: runShellCommand
        Variable: "{{GetInstance.platform}}"
        StringEquals: Linux
    Default:
      PostProcessing
```

## Creating an `aws:branch` step in a runbook

When you create an `aws:branch` step in a runbook, you define the `Choices` the automation should evaluate to determine which step the automation should jump to next. As noted earlier, `Choices` are evaluated by using a Boolean expression. Each choice must define the following options:

- **NextStep:** The next step in the runbook to process if the designated choice is `true`.
- **Variable:** Specify either the name of a parameter that is defined in the `Parameters` section of the runbook, a variable defined in the `Variables` section, or specify an output object from a previous step.

Specify variable values by using the following form.

```
Variable: "{{variable name}}"
```

Specify parameter values by using the following form.

Variable: "`{{parameter name}}`"

Specify output object variables by using the following form.

Variable: "`{{previousStepName.outputName}}`"

 **Note**

Creating the output variable is described in more detail in the next section, [About creating the output variable](#).

- **Operation:** The criteria used to evaluate the choice, such as `StringEquals: Linux`. The `aws:branch` action supports the following operations:

### String operations

- `StringEquals`
- `EqualsIgnoreCase`
- `StartsWith`
- `EndsWith`
- `Contains`

### Numeric operations

- `NumericEquals`
- `NumericGreater`
- `NumericLesser`
- `NumericGreaterOrEquals`
- `NumericLesser`
- `NumericLesserOrEquals`

### Boolean operation

- `BooleanEquals`

**⚠ Important**

When you create a runbook, the system validates each operation in the runbook. If an operation isn't supported, the system returns an error when you try to create the runbook.

- **Default:** Specify a fallback step that the automation should jump to if none of the Choices are true.

**ℹ Note**

If you don't want to specify a Default value, then you can specify the `isEnd` option. If none of the Choices are true and no Default value is specified, then the automation stops at the end of the step.

Use the following templates to help you construct the `aws:branch` step in your runbook. Replace each *example resource placeholder* with your own information.

**YAML**

```
mainSteps:
- name: step name
  action: aws:branch
  inputs:
    Choices:
    - NextStep: step to jump to if evaluation for this choice is true
      Variable: "{{parameter name or output from previous step}}"
      Operation type: Operation value
    - NextStep: step to jump to if evaluation for this choice is true
      Variable: "{{parameter name or output from previous step}}"
      Operation type: Operation value
    Default:
      step to jump to if all choices are false
```

**JSON**

```
{
  "mainSteps": [
```

```

    {
      "name": "a name for the step",
      "action": "aws:branch",
      "inputs": {
        "Choices": [
          {
            "NextStep": "step to jump to if evaluation for this choice is
true",
            "Variable": "{{parameter name or output from previous step}}",
            "Operation type": "Operation value"
          },
          {
            "NextStep": "step to jump to if evaluation for this choice is
true",
            "Variable": "{{parameter name or output from previous step}}",
            "Operation type": "Operation value"
          }
        ],
        "Default": "step to jump to if all choices are false"
      }
    }
  ]
}

```

## About creating the output variable

To create an `aws:branch` choice that references the output from a previous step, you need to identify the name of the previous step and the name of the output field. You then combine the names of the step and the field by using the following format.

Variable: `"{{previousStepName.outputName}}"`

For example, the first step in the following example is named `GetInstance`. And then, under outputs, there is a field called `platform`. In the second step (`ChooseOSforCommands`), the author wants to reference the output from the `platform` field as a variable. To create the variable, simply combine the step name (`GetInstance`) and the output field name (`platform`) to create Variable: `"{{GetInstance.platform}}"`.

```

mainSteps:
- Name: GetInstance
  action: aws:executeAwsApi
  inputs:

```

```

Service: ssm
Api: DescribeInstanceInformation
Filters:
- Key: InstanceIds
  Values: ["{{ InstanceId }}"]
outputs:
- Name: myInstance
  Selector: "$.InstanceInformationList[0].InstanceId"
  Type: String
- Name: platform
  Selector: "$.InstanceInformationList[0].PlatformType"
  Type: String
- name: ChooseOSforCommands
  action: aws:branch
  inputs:
    Choices:
    - NextStep: runPowerShellCommand
      Variable: "{{GetInstance.platform}}"
      StringEquals: Windows
    - NextStep: runShellCommand
      Variable: "{{GetInstance.platform}}"
      StringEquals: Linux
  Default:
    Sleep

```

Here is an example that shows how *"Variable": "{{ describeInstance.Platform }}"* is created from the previous step and the output.

```

- name: describeInstance
  action: aws:executeAwsApi
  onFailure: Abort
  inputs:
    Service: ec2
    Api: DescribeInstances
    InstanceIds:
    - "{{ InstanceId }}"
  outputs:
    - Name: Platform
      Selector: "$.Reservations[0].Instances[0].Platform"
      Type: String
  nextStep: branchOnInstancePlatform
- name: branchOnInstancePlatform
  action: aws:branch

```

```
inputs:
  Choices:
  - NextStep: runEC2RescueForWindows
    Variable: "{{ describeInstance.Platform }}"
    StringEquals: windows
  Default: runEC2RescueForLinux
```

## Example aws:branch runbooks

Here are some example runbooks that use `aws:branch`.

### Example 1: Using `aws:branch` with an output variable to run commands based on the operating system type

In the first step of this example (`GetInstance`), the runbook author uses the `aws:executeAwsApi` action to call the `ssm DescribeInstanceInformation` API operation. The author uses this action to determine the type of operating system being used by an instance. The `aws:executeAwsApi` action outputs the instance ID and the platform type.

In the second step (`ChooseOSforCommands`), the author uses the `aws:branch` action with two Choices (`NextStep: runPowerShellCommand`) and (`NextStep: runShellCommand`). The automation evaluates the operating system of the instance by using the output from the previous step (`Variable: "{{ GetInstance.platform }}"`). The automation jumps to a step for the designated operating system.

```
---
schemaVersion: '0.3'
assumeRole: "{{AutomationAssumeRole}}"
parameters:
  AutomationAssumeRole:
    default: ""
    type: String
mainSteps:
- name: GetInstance
  action: aws:executeAwsApi
  inputs:
    Service: ssm
    Api: DescribeInstanceInformation
  outputs:
  - Name: myInstance
    Selector: "$.InstanceInformationList[0].InstanceId"
```

```

    Type: String
  - Name: platform
    Selector: "$.InstanceInformationList[0].PlatformType"
    Type: String
  - name: ChooseOSforCommands
    action: aws:branch
    inputs:
      Choices:
        - NextStep: runPowerShellCommand
          Variable: "{{GetInstance.platform}}"
          StringEquals: Windows
        - NextStep: runShellCommand
          Variable: "{{GetInstance.platform}}"
          StringEquals: Linux
      Default:
        Sleep
  - name: runShellCommand
    action: aws:runCommand
    inputs:
      DocumentName: AWS-RunShellScript
      InstanceIds:
        - "{{GetInstance.myInstance}}"
      Parameters:
        commands:
          - ls
    isEnd: true
  - name: runPowerShellCommand
    action: aws:runCommand
    inputs:
      DocumentName: AWS-RunPowerShellScript
      InstanceIds:
        - "{{GetInstance.myInstance}}"
      Parameters:
        commands:
          - ls
    isEnd: true
  - name: Sleep
    action: aws:sleep
    inputs:
      Duration: PT3S

```

## Example 2: Using `aws:branch` with a parameter variable to run commands based on the operating system type

The runbook author defines several parameter options at the beginning of the runbook in the `parameters` section. One parameter is named `OperatingSystemName`. In the first step (`ChooseOS`), the author uses the `aws:branch` action with two Choices (`NextStep: runWindowsCommand`) and (`NextStep: runLinuxCommand`). The variable for these Choices references the parameter option specified in the parameters section (`Variable: "{{OperatingSystemName}}"`). When the user runs this runbook, they specify a value at runtime for `OperatingSystemName`. The automation uses the runtime parameter during the Choices evaluation. The automation jumps to a step for the designated operating system based on the runtime parameter specified for `OperatingSystemName`.

```
---
schemaVersion: '0.3'
assumeRole: "{{AutomationAssumeRole}}"
parameters:
  AutomationAssumeRole:
    default: ""
    type: String
  OperatingSystemName:
    type: String
  LinuxInstanceId:
    type: String
  WindowsInstanceId:
    type: String
mainSteps:
- name: ChooseOS
  action: aws:branch
  inputs:
    Choices:
      - NextStep: runWindowsCommand
        Variable: "{{OperatingSystemName}}"
        StringEquals: windows
      - NextStep: runLinuxCommand
        Variable: "{{OperatingSystemName}}"
        StringEquals: linux
    Default:
      Sleep
- name: runLinuxCommand
  action: aws:runCommand
  inputs:
    DocumentName: "AWS-RunShellScript"
    InstanceIds:
      - "{{LinuxInstanceId}}"
```

```

Parameters:
  commands:
    - ls
isEnd: true
- name: runWindowsCommand
  action: aws:runCommand
  inputs:
    DocumentName: "AWS-RunPowerShellScript"
    InstanceIds:
      - "{{WindowsInstanceId}}"
    Parameters:
      commands:
        - date
isEnd: true
- name: Sleep
  action: aws:sleep
  inputs:
    Duration: PT3S

```

## Creating complex branching automations with operators

You can create complex branching automations by using the `And`, `Or`, and `Not` operators in your `aws:branch` steps.

### The 'And' operator

Use the `And` operator when you want multiple variables to be `true` for a choice. In the following example, the first choice evaluates if an instance is `running` and uses the `Windows` operating system. If the evaluation of *both* of these variables is `true`, then the automation jumps to the `runPowerShellCommand` step. If one or more of the variables is `false`, then the automation evaluates the variables for the second choice.

```

mainSteps:
- name: switch2
  action: aws:branch
  inputs:
    Choices:
      - And:
          - Variable: "{{GetInstance.pingStatus}}"
            StringEquals: running
          - Variable: "{{GetInstance.platform}}"
            StringEquals: Windows

```

```
NextStep: runPowerShellCommand

- And:
  - Variable: "{{GetInstance.pingStatus}}"
    StringEquals: running
  - Variable: "{{GetInstance.platform}}"
    StringEquals: Linux
  NextStep: runShellCommand
Default:
  sleep3
```

## The 'Or' operator

Use the `Or` operator when you want *any* of multiple variables to be true for a choice. In the following example, the first choice evaluates if a parameter string is `Windows` and if the output from an AWS Lambda step is true. If the evaluation determines that *either* of these variables is true, then the automation jumps to the `RunPowerShellCommand` step. If both variables are false, then the automation evaluates the variables for the second choice.

```
- Or:
  - Variable: "{{parameter1}}"
    StringEquals: Windows
  - Variable: "{{BooleanParam1}}"
    BooleanEquals: true
  NextStep: RunPowershellCommand
- Or:
  - Variable: "{{parameter2}}"
    StringEquals: Linux
  - Variable: "{{BooleanParam2}}"
    BooleanEquals: true
  NextStep: RunShellScript
```

## The 'Not' operator

Use the `Not` operator when you want to jump to a step defined when a variable is *not* true. In the following example, the first choice evaluates if a parameter string is `Not Linux`. If the evaluation determines that the variable isn't `Linux`, then the automation jumps to the `sleep2` step. If the evaluation of the first choice determines that it *is* `Linux`, then the automation evaluates the next choice.

```
mainSteps:
```

```

- name: switch
  action: aws:branch
  inputs:
    Choices:
      - NextStep: sleep2
        Not:
          Variable: "{{testParam}}"
          StringEquals: Linux
      - NextStep: sleep1
        Variable: "{{testParam}}"
        StringEquals: Windows
    Default:
      sleep3

```

## Examples of how to use conditional options

This section includes different examples of how to use dynamic options in a runbook. Each example in this section extends the following runbook. This runbook has two actions. The first action is named `InstallMsiPackage`. It uses the `aws:runCommand` action to install an application on a Windows Server instance. The second action is named `TestInstall`. It uses the `aws:invokeLambdaFunction` action to perform a test of the installed application if the application installed successfully. Step one specifies `onFailure: Abort`. This means that if the application didn't install successfully, the automation stops before step two.

### Example 1: Runbook with two linear actions

```

---
schemaVersion: '0.3'
description: Install MSI package and run validation.
assumeRole: "{{automationAssumeRole}}"
parameters:
  automationAssumeRole:
    type: String
    description: "(Required) Assume role."
  packageName:
    type: String
    description: "(Required) MSI package to be installed."
  instanceIds:
    type: String
    description: "(Required) Comma separated list of instances."
mainSteps:
- name: InstallMsiPackage

```

```

action: aws:runCommand
maxAttempts: 2
onFailure: Abort
inputs:
  InstanceIds:
  - "{{instanceIds}}"
  DocumentName: AWS-RunPowerShellScript
  Parameters:
    commands:
    - msiexec /i {{packageName}}
- name: TestInstall
  action: aws:invokeLambdaFunction
  maxAttempts: 1
  timeoutSeconds: 500
  inputs:
    FunctionName: TestLambdaFunction
...

```

## Creating a dynamic automation that jumps to different steps by using the onFailure option

The following example uses the onFailure: step:*step name*, nextStep, and isEnd options to create a dynamic automation. With this example, if the InstallMsiPackage action fails, then the automation jumps to an action called *PostFailure* (onFailure: step:PostFailure) to run an AWS Lambda function to perform some action in the event the install failed. If the install succeeds, then the automation jumps to the TestInstall action (nextStep: TestInstall). Both the TestInstall and the PostFailure steps use the isEnd option (isEnd: true) so that the automation finishes when either of those steps is completed.

### Note

Using the isEnd option in the last step of the mainSteps section is optional. If the last step doesn't jump to other steps, then the automation stops after running the action in the last step.

## Example 2: A dynamic automation that jumps to different steps

```

mainSteps
- name: InstallMsiPackage
  action: aws:runCommand
  onFailure: step:PostFailure

```

```
maxAttempts: 2
inputs:
  InstanceIds:
  - "{{instanceIds}}"
  DocumentName: AWS-RunPowerShellScript
  Parameters:
    commands:
    - msiexec /i {{packageName}}
nextStep: TestInstall
- name: TestInstall
  action: aws:invokeLambdaFunction
  maxAttempts: 1
  timeoutSeconds: 500
  inputs:
    FunctionName: TestLambdaFunction
  isEnd: true
- name: PostFailure
  action: aws:invokeLambdaFunction
  maxAttempts: 1
  timeoutSeconds: 500
  inputs:
    FunctionName: PostFailureRecoveryLambdaFunction
  isEnd: true
...
```

### Note

Before processing a runbook, the system verifies that the runbook doesn't create an infinite loop. If an infinite loop is detected, Automation returns an error and a circle trace showing which steps create the loop.

## Creating a dynamic automation that defines critical steps

You can specify that a step is critical for the overall success of the automation. If a critical step fails, then Automation reports the status of the automation as `Failed`, even if one or more steps ran successfully. In the following example, the user identifies the `VerifyDependencies` step if the `InstallMsiPackage` step fails (`onFailure: step:VerifyDependencies`). The user specifies that the `InstallMsiPackage` step isn't critical (`isCritical: false`). In this example, if the application failed to install, Automation processes the `VerifyDependencies` step to determine if one or more dependencies is missing, which therefore caused the application install to fail.

### Example 3: Defining critical steps for the automation

```
---
name: InstallMsiPackage
action: aws:runCommand
onFailure: step:VerifyDependencies
isCritical: false
maxAttempts: 2
inputs:
  InstanceIds:
  - "{{instanceIds}}"
  DocumentName: AWS-RunPowerShellScript
  Parameters:
    commands:
    - msixexec /i {{packageName}}
nextStep: TestPackage
...
```

### Using action outputs as inputs

Several automation actions return pre-defined outputs. You can pass these outputs as inputs to later steps in your runbook using the format `{{stepName.outputName}}`. You can also define custom outputs for automation actions in your runbooks. This allows you to run scripts, or invoke API operations for other AWS services once so you can reuse the values as inputs in later actions. Parameter types in runbooks are static. This means the parameter type can't be changed after it's defined. To define a step output provide the following fields:

- **Name:** (Required) The output name which is used to reference the output value in later steps.
- **Selector:** (Required) The JSONPath expression that is used to determine the output value.
- **Type:** (Optional) The data type of the value returned by the selector field. Valid type values are `String`, `Integer`, `Boolean`, `StringList`, `StringMap`, `MapList`. The default value is `String`.

If the value of an output doesn't match the data type you've specified, Automation tries to convert the data type. For example, if the value returned is an `Integer`, but the `Type` specified is `String`, the final output value is a `String` value. The following type conversions are supported:

- `String` values can be converted to `StringList`, `Integer` and `Boolean`.
- `Integer` values can be converted to `String` and `StringList`.
- `Boolean` values can be converted to `String` and `StringList`.

- `StringList`, `IntegerList`, or `BooleanList` values containing one element can be converted to `String`, `Integer`, or `Boolean`.

When using parameters or outputs with automation actions, the data type can't be dynamically changed within an action's input.

Here is an example runbook that demonstrates how to define action outputs, and reference the value as input for a later action. The runbooks does the following:

- Uses the `aws:executeAwsApi` action to call the Amazon EC2 `DescribeImages` API operation to get the name of a specific Windows Server 2016 AMI. It outputs the image ID as `ImageId`.
- Uses the `aws:executeAwsApi` action to call the Amazon EC2 `RunInstances` API operation to launch one instance that uses the `ImageId` from the previous step. It outputs the instance ID as `InstanceId`.
- Uses the `aws:waitForAwsResourceProperty` action to poll the Amazon EC2 `DescribeInstanceStatus` API operation to wait for the instance to reach the `running` state. The action times out in 60 seconds. The step times out if the instance state failed to reach `running` after 60 seconds of polling.
- Uses the `aws:assertAwsResourceProperty` action to call the Amazon EC2 `DescribeInstanceStatus` API operation to assert that the instance is in the `running` state. The step fails if the instance state isn't `running`.

```
---
description: Sample runbook using AWS API operations
schemaVersion: '0.3'
assumeRole: "{{ AutomationAssumeRole }}"
parameters:
  AutomationAssumeRole:
    type: String
    description: "(Optional) The ARN of the role that allows Automation to perform the
actions on your behalf."
    default: ''
  ImageName:

  inputs:
    Service: ec2
    Api: RunInstances
    ImageId: "{{ getImageId.ImageId }}"
    MaxCount: 1
    MinCount: 1
  outputs:
    - Name: InstanceId
      Selector: "$.Instances[0].InstanceId"
      Type: "String"
- name: waitUntilInstanceStateRunning
  action: aws:waitForAwsResourceProperty
  timeoutSeconds: 60
  inputs:
    Service: ec2
    Api: DescribeInstanceStatus
    InstanceIds:
      - "{{ launchOneInstance.InstanceId }}"
    PropertySelector: "$.InstanceStatuses[0].InstanceState.Name"
    DesiredValues:
      - running
- name: assertInstanceStateRunning
  action: aws:assertAwsResourceProperty
  inputs:
    Service: ec2
    Api: DescribeInstanceStatus
    InstanceIds:
      - "{{ launchOneInstance.InstanceId }}"
    PropertySelector: "$.InstanceStatuses[0].InstanceState.Name"
    DesiredValues:
```

```
- running
outputs:
- "launchOneInstance.InstanceId"
...
```

Each of the previously described automation actions allows you to call a specific API operation by specifying the service namespace, the API operation name, the input parameters, and the output parameters. Inputs are defined by the API operation that you choose. You can view the API operations (also called methods) by choosing a service in the left navigation on the following [Services Reference](#) page. Choose a method in the **Client** section for the service that you want to invoke. For example, all API operations (methods) for Amazon Relational Database Service (Amazon RDS) are listed on the following page: [Amazon RDS methods](#).

You can view the schema for each automation action in the following locations:

- [aws:assertAwsResourceProperty – Assert an AWS resource state or event state](#)
- [aws:executeAwsApi – Call and run AWS API operations](#)
- [aws:waitForAwsResourceProperty – Wait on an AWS resource property](#)

The schemas include descriptions of the required fields for using each action.

### Using the Selector/PropertySelector fields

Each Automation action requires that you specify either an output Selector (for `aws:executeAwsApi`) or a PropertySelector (for `aws:assertAwsResourceProperty` and `aws:waitForAwsResourceProperty`). These fields are used to process the JSON response from an AWS API operation. These fields use the JSONPath syntax.

Here is an example to help illustrate this concept for the `aws:executeAwsApi` action.

```
---
mainSteps:
- name: getImageId
  action: aws:executeAwsApi
  inputs:
    Service: ec2
    Api: DescribeImages
    Filters:
      - Name: "name"
      Values:
```

```

    - "{{ ImageName }}"
  outputs:
    - Name: ImageId
      Selector: "$.Images[0].ImageId"
      Type: "String"
  ...

```

In the `aws:executeAwsApi` step `getImageId`, the automation invokes the `DescribeImages` API operation and receives a response from `ec2`. The automation then applies `Selector` - `"$.Images[0].ImageId"` to the API response and assigns the selected value to the output `ImageId` variable. Other steps in the same automation can use the value of `ImageId` by specifying `"{{ getImageId.ImageId }}"`.

Here is an example to help illustrate this concept for the `aws:waitForAwsResourceProperty` action.

```

---
- name: waitUntilInstanceStateRunning
  action: aws:waitForAwsResourceProperty
  # timeout is strongly encouraged for action - aws:waitForAwsResourceProperty
  timeoutSeconds: 60
  inputs:
    Service: ec2
    Api: DescribeInstanceStatus
    InstanceIds:
      - "{{ launchOneInstance.InstanceId }}"
    PropertySelector: "$.InstanceStatuses[0].InstanceState.Name"
    DesiredValues:
      - running
  ...

```

In the `aws:waitForAwsResourceProperty` step `waitUntilInstanceStateRunning`, the automation invokes the `DescribeInstanceStatus` API operation and receives a response from `ec2`. The automation then applies `PropertySelector` - `"$.InstanceStatuses[0].InstanceState.Name"` to the response and checks if the specified returned value matches a value in the `DesiredValues` list (in this case `running`). The step repeats the process until the response returns an instance state of `running`.

## Using JSONPath in runbooks

A JSONPath expression is a string beginning with "\$." that is used to select one of more components within a JSON element. The following list includes information about JSONPath operators that are supported by Systems Manager Automation:

- **Dot-notated child (.):** Use with a JSON object. This operator selects the value of a specific key.
- **Deep-scan (..):** Use with a JSON element. This operator scans the JSON element level by level and selects a list of values with the specific key. The return type of this operator is always a JSON array. In the context of an automation action output type, the operator can be either `StringList` or `MapList`.
- **Array-Index ([ ]):** Use with a JSON array. This operator gets the value of a specific index.
- **Filter ([?(*expression*)]):** Use with a JSON array. This operator filters JSON array values that match the criteria defined in the filter expression. Filter expressions can only use the following operators: `==`, `!=`, `>`, `<`, `>=`, or `<=`. Combining multiple filter expressions with AND (`&&`) or OR (`||`) is not supported. The return type of this operator is always a JSON array.

To better understand JSONPath operators, review the following JSON response from the `ec2 DescribeInstances` API operation. Following this response are several examples that show different results by applying different JSONPath expressions to the response from the `DescribeInstances` API operation.

```
{
  "NextToken": "abcdefg",
  "Reservations": [
    {
      "OwnerId": "123456789012",
      "ReservationId": "r-abcd12345678910",
      "Instances": [
        {
          "ImageId": "ami-12345678",
          "BlockDeviceMappings": [
            {
              "Ebs": {
                "DeleteOnTermination": true,
                "Status": "attached",
                "VolumeId": "vol-00000000000000"
              },
              "DeviceName": "/dev/xvda"
            }
          ]
        }
      ]
    }
  ]
}
```

```

        }
      ],
      "State": {
        "Code": 16,
        "Name": "running"
      }
    }
  ],
  "Groups": []
},
{
  "OwnerId": "123456789012",
  "ReservationId": "r-12345678910abcd",
  "Instances": [
    {
      "ImageId": "ami-12345678",
      "BlockDeviceMappings": [
        {
          "Ebs": {
            "DeleteOnTermination": true,
            "Status": "attached",
            "VolumeId": "vol-111111111111"
          },
          "DeviceName": "/dev/xvda"
        }
      ],
      "State": {
        "Code": 80,
        "Name": "stopped"
      }
    }
  ],
  "Groups": []
}
]
}

```

### JSONPath Example 1: Get a specific String from a JSON response

JSONPath:  
\$.Reservations[0].Instances[0].ImageId

Returns:

```
"ami-12345678"
```

Type: String

### JSONPath Example 2: Get a specific Boolean from a JSON response

JSONPath:

```
$.Reservations[0].Instances[0].BlockDeviceMappings[0].Ebs.DeleteOnTermination
```

Returns:

```
true
```

Type: Boolean

### JSONPath Example 3: Get a specific Integer from a JSON response

JSONPath:

```
$.Reservations[0].Instances[0].State.Code
```

Returns:

```
16
```

Type: Integer

### JSONPath Example 4: Deep scan a JSON response, then get all of the values for VolumeId as a StringList

JSONPath:

```
$.Reservations..BlockDeviceMappings..VolumeId
```

Returns:

```
[  
  "vol-00000000000000",  
  "vol-11111111111111"  
]
```

Type: StringList

### JSONPath Example 5: Get a specific BlockDeviceMappings object as a StringMap

JSONPath:

```
$.Reservations[0].Instances[0].BlockDeviceMappings[0]
```

Returns:

```
{
  "Ebs" : {
    "DeleteOnTermination" : true,
    "Status" : "attached",
    "VolumeId" : "vol-00000000000000"
  },
  "DeviceName" : "/dev/xvda"
}
```

Type: StringMap

### JSONPath Example 6: Deep scan a JSON response, then get all of the State objects as a MapList

JSONPath:

```
$.Reservations..Instances..State
```

Returns:

```
[
  {
    "Code" : 16,
    "Name" : "running"
  },
  {
    "Code" : 80,
    "Name" : "stopped"
  }
]
```

Type: MapList

### JSONPath Example 7: Filter for instances in the running state

JSONPath:

```
$.Reservations..Instances[?(@.State.Name == 'running')]
```

Returns:

```
[
  {
    "ImageId": "ami-12345678",
    "BlockDeviceMappings": [
```

```
{
  "Ebs": {
    "DeleteOnTermination": true,
    "Status": "attached",
    "VolumeId": "vol-00000000000000"
  },
  "DeviceName": "/dev/xvda"
},
"State": {
  "Code": 16,
  "Name": "running"
}
]
```

Type: MapList

### JSONPath Example 8: Return the ImageId of instances which aren't in the running state

JSONPath:

```
$.Reservations..Instances[?(@.State.Name != 'running')].ImageId
```

Returns:

```
[
  "ami-12345678"
]
```

Type: StringList | String

## Creating webhook integrations for Automation

To send messages using webhooks during an automation, create an integration. Integrations can be invoked during an automation by using the `aws:invokeWebhook` action in your runbook. If you haven't already created a webhook, see [Creating webhooks for integrations](#). To learn more about the `aws:invokeWebhook` action, see [aws:invokeWebhook – Invoke an Automation webhook integration](#).

As shown in the following procedures, you can create an integration by using either the Systems Manager Automation console or your preferred command line tool.

## Creating integrations (console)

### To create an integration for Automation (console)

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Automation**.
3. Choose the **Integrations** tab.
4. Select **Add integration**, and choose **Webhook**.
5. Enter the required values and any optional values you want to include for the integration.
6. Choose **Add** to create the integration.

### Creating integrations (command line)

To create an integration using command line tools, you must create the required `SecureString` parameter for an integration. Automation uses a reserved namespace in Parameter Store, a capability of Systems Manager, to store information about your integration. If you create an integration using the AWS Management Console, Automation handles this process for you. Following the namespace, you must specify the type of integration you want to create and then the name of your integration. Currently, Automation supports webhook type integrations.

The supported fields for webhook type integrations are as follows:

- Description
- headers
- payload
- URL

### Before you begin

If you haven't already, install and configure the AWS Command Line Interface (AWS CLI) or the AWS Tools for PowerShell. For information, see [Installing or updating the latest version of the AWS CLI](#) and [Installing the AWS Tools for PowerShell](#).

## To create an integration for Automation (command line)

- Run the following commands to create the required SecureString parameter for an integration. Replace each *example resource placeholder* with your own information. The `/d9d01087-4a3f-49e0-b0b4-d568d7826553/ssm/integrations/webhook/` namespace is reserved in Parameter Store for integrations. The name of your parameter must use this namespace followed by the name of your integration. For example `/d9d01087-4a3f-49e0-b0b4-d568d7826553/ssm/integrations/webhook/myWebhookIntegration`.

### Linux & macOS

```
aws ssm put-parameter \  
  --name "/d9d01087-4a3f-49e0-b0b4-d568d7826553/ssm/integrations/  
webhook/myWebhookIntegration" \  
  --type "SecureString" \  
  --data-type "aws:ssm:integration" \  
  --value '{"description": "My first webhook integration for Automation.",  
"url": "myWebHookURL"}'
```

### Windows

```
aws ssm put-parameter ^  
  --name "/d9d01087-4a3f-49e0-b0b4-d568d7826553/ssm/integrations/  
webhook/myWebhookIntegration" ^  
  --type "SecureString" ^  
  --data-type "aws:ssm:integration" ^  
  --value "{\"description\": \"My first webhook integration for Automation.\",  
\"url\": \"myWebHookURL\"}"
```

### PowerShell

```
Write-SSMParameter `  
  -Name "/d9d01087-4a3f-49e0-b0b4-d568d7826553/ssm/integrations/  
webhook/myWebhookIntegration" `  
  -Type "SecureString"  
  -DataType "aws:ssm:integration"  
  -Value '{"description": "My first webhook integration for Automation.",  
"url": "myWebHookURL"}'
```

## Creating webhooks for integrations

When creating webhooks with your provider, note the following:

- Protocol must be HTTPS.
- Custom request headers are supported.
- A default request body can be specified.
- The default request body can be overridden when an integration is invoked by using the `aws:invokeWebhook` action.

## Handling timeouts in runbooks

The `timeoutSeconds` property is shared by all automation actions. You can use this property to specify the execution timeout value for an action. Further, you can change how an action timing out affects the automation and overall execution status. You can accomplish this by also defining the `onFailure` and `isCritical` shared properties for an action.

For example, depending on your use case, you might want your automation to continue to a different action and not affect the overall status of the automation if an action times out. In this example, you specify the length of time to wait before the action times out using the `timeoutSeconds` property. Then you specify the action, or step, the automation should go to if there is a timeout. Specify a value using the format `step: step name` for the `onFailure` property rather than the default value of `Abort`. By default, if an action times out, the automation execution status will be `Timed Out`. To prevent a timeout from affecting the automation execution status, specify `false` for the `isCritical` property.

The following example shows how to define the shared properties for an action described in this scenario.

### YAML

```
- name: verifyImageAvailability
  action: 'aws:waitForAwsResourceProperty'
  timeoutSeconds: 600
  isCritical: false
  onFailure: 'step:getCurrentImageState'
  inputs:
    Service: ec2
    Api: DescribeImages
```

```
ImageIds:
  - '{{ createImage.newImageId }}'
PropertySelector: '$.Images[0].State'
DesiredValues:
  - available
nextStep: copyImage
```

## JSON

```
{
  "name": "verifyImageAvailability",
  "action": "aws:waitForAwsResourceProperty",
  "timeoutSeconds": 600,
  "isCritical": false,
  "onFailure": "step:getCurrentImageState",
  "inputs": {
    "Service": "ec2",
    "Api": "DescribeImages",
    "ImageIds": [
      "{{ createImage.newImageId }}"
    ],
    "PropertySelector": "$.Images[0].State",
    "DesiredValues": [
      "available"
    ]
  },
  "nextStep": "copyImage"
}
```

For more information about properties shared by all automation actions, see [Properties shared by all actions](#).

## Systems Manager Automation runbook reference

To help you get started quickly, AWS Systems Manager provides predefined runbooks. These runbooks are maintained by Amazon Web Services, AWS Support, and AWS Config. The runbook reference describes each of the predefined runbooks provided by Systems Manager, AWS Support, and AWS Config. For more information, see [Systems Manager Automation runbook reference](#).

## Tutorials

The following tutorials help you to use AWS Systems Manager Automation to address common use cases. These tutorials demonstrate how to use your own runbooks, predefined runbooks provided by Automation, and other Systems Manager capabilities with other AWS services.

## Update a Linux AMI

This Systems Manager Automation walkthrough shows you how to use the console or AWS CLI and the `AWS-UpdateLinuxAmi` runbook to update a Linux AMI with the latest patches of packages that you specify. Automation is a capability of AWS Systems Manager. The `AWS-UpdateLinuxAmi` runbook also automates the installation of additional site-specific packages and configurations. You can update a variety of Linux distributions using this walkthrough, including Ubuntu Server, CentOS, RHEL, SLES, or Amazon Linux AMIs. For a full list of supported Linux versions, see [Patch Manager prerequisites](#).

The `AWS-UpdateLinuxAmi` runbook allows you to automate image maintenance tasks without having to author the runbook in JSON or YAML. You can use the `AWS-UpdateLinuxAmi` runbook to perform the following types of tasks.

- Upgrade all distribution packages and Amazon software on an Amazon Linux, Red Hat Enterprise Linux, Ubuntu Server, SUSE Linux Enterprise Server, or CentOS Amazon Machine Image (AMI). This is the default runbook behavior.

- Install AWS Systems Manager SSM Agent on an existing image to enable Systems Manager capabilities, such as running remote commands using AWS Systems Manager Run Command or software inventory collection using Inventory.
- Install additional software packages.

## Before you begin

Before you begin working with runbooks, configure roles and, optionally, EventBridge for Automation. For more information, see [Setting up Automation](#). This walkthrough also requires that you specify the name of an AWS Identity and Access Management (IAM) instance profile. For more information about creating an IAM instance profile, see [Configure instance permissions required for Systems Manager](#).

The AWS-UpdateLinuxAmi runbook accepts the following input parameters.

| Parameter              | Type   | Description   |
|------------------------|--------|---|
| SourceAmiId            | String | (Required) The source AMI ID.   |
| IamInstanceProfileName | String | (Required) The name of the IAM instance profile role you created in <a href="#">Configure instance permissions required for Systems Manager</a> . The instance profile role gives Automation permission to perform actions on your instances, such as running commands or starting and stopping services. The runbook uses only the name of the instance profile role. If you specify the Amazon Resource Name (ARN), the automation fails. |
| AutomationAssumeRole   | String | (Required) The name of the IAM service role you created   |

| Parameter        | Type   | Description   |
|------------------|--------|---|
|                  |        | <p>in <a href="#">Setting up Automation</a>. The service role (also called an assume role) gives Automation permission to assume your IAM role and perform actions on your behalf. For example, the service role allows Automation to create a new AMI when running the <code>aws:createImage</code> action in a runbook. For this parameter, the complete ARN must be specified.</p> |
| TargetAmiName    | String | <p>(Optional) The name of the new AMI after it is created. The default name is a system-generated string that includes the source AMI ID, and the creation time and date.</p>   |
| InstanceType     | String | <p>(Optional) The type of instance to launch as the workspace host. Instance types vary by region. The default type is <code>t2.micro</code>.</p>   |
| PreUpdateScript  | String | <p>(Optional) URL of a script to run before updates are applied. Default (<code>\\"none\\"</code>) is to not run a script.</p>  |
| PostUpdateScript | String | <p>(Optional) URL of a script to run after package updates are applied. Default (<code>\\"none\\"</code>) is to not run a script.</p>   |

| Parameter       | Type   | Description   |
|-----------------|--------|---|
| IncludePackages | String | (Optional) Only update these named packages. By default ( <code>\\"all\\"</code> ), all available updates are applied.                        |
| ExcludePackages | String | (Optional) Names of packages to hold back from updates, under all conditions. By default ( <code>\\"none\\"</code> ), no package is excluded. |

## Automation Steps

The `AWS-UpdateLinuxAmi` runbook includes the following automation actions, by default.

### Step 1: `launchInstance` (`aws:runInstances` action)

This step launches an instance using Amazon Elastic Compute Cloud (Amazon EC2) userdata and an IAM instance profile role. Userdata installs the appropriate SSM Agent, based on the operating system. Installing SSM Agent enables you to utilize Systems Manager capabilities such as Run Command, State Manager, and Inventory.

### Step 2: `updateOSSoftware` (`aws:runCommand` action)

This step runs the following commands on the launched instance:

- Downloads an update script from Amazon S3.
- Runs an optional pre-update script.
- Updates distribution packages and Amazon software.
- Runs an optional post-update script.

The execution log is stored in the `/tmp` folder for the user to view later.

If you want to upgrade a specific set of packages, you can supply the list using the `IncludePackages` parameter. When provided, the system attempts to update only these packages and their dependencies. No other updates are performed. By default, when no *include* packages are specified, the program updates all available packages.

If you want to exclude upgrading a specific set of packages, you can supply the list to the `ExcludePackages` parameter. If provided, these packages remain at their current version, independent of any other options specified. By default, when no *exclude* packages are specified, no packages are excluded.

### Step 3: stopInstance (aws : changeInstanceState action)

This step stops the updated instance.

### Step 4: createImage (aws : createImage action)

This step creates a new AMI with a descriptive name that links it to the source ID and creation time. For example: "AMI Generated by EC2 Automation on {{global:DATE\_TIME}} from {{SourceAmiID}}" where `DATE_TIME` and `SourceID` represent Automation variables.

### Step 5: terminateInstance (aws : changeInstanceState action)

This step cleans up the automation by terminating the running instance.

## Output

The automation returns the new AMI ID as output.

#### Note

By default, when Automation runs the `AWS-UpdateLinuxAmi` runbook, the system creates a temporary instance in the default VPC (172.30.0.0/16). If you deleted the default VPC, you will receive the following error:

```
VPC not defined 400
```

To solve this problem, you must make a copy of the `AWS-UpdateLinuxAmi` runbook and specify a subnet ID. For more information, see [VPC not defined 400](#).

## To create a patched AMI using Automation (AWS Systems Manager)

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Automation**.
3. Choose **Execute automation**.
4. In the **Automation document** list, choose **AWS-UpdateLinuxAmi**.

5. In the **Document details** section, verify that **Document version** is set to **Default version at runtime**.
6. Choose **Next**.
7. In the **Execution mode** section, choose **Simple Execution**.
8. In the **Input parameters** section, enter the information you collected in the **Before you begin** section.
9. Choose **Execute**. The console displays the status of the Automation execution.

After the automation finishes, launch a test instance from the updated AMI to verify changes.

#### Note

If any step in the automation fails, information about the failure is listed on the **Automation Executions** page. The automation is designed to terminate the temporary instance after successfully completing all tasks. If a step fails, the system might not terminate the instance. So if a step fails, manually terminate the temporary instance.

## Update a Linux AMI (AWS CLI)

This AWS Systems Manager Automation walkthrough shows you how to use the AWS Command Line Interface (AWS CLI) and the Systems Manager `AWS-UpdateLinuxAmi` runbook to automatically patch a Linux Amazon Machine Image (AMI) with the latest versions of packages that you specify. Automation is a capability of AWS Systems Manager. The `AWS-UpdateLinuxAmi` runbook also automates the installation of additional site-specific packages and configurations. You can update a variety of Linux distributions using this walkthrough, including Ubuntu Server, CentOS, RHEL, SLES, or Amazon Linux AMIs. For a full list of supported Linux versions, see [Patch Manager prerequisites](#).

The `AWS-UpdateLinuxAmi` runbook enables you to automate image-maintenance tasks without having to author the runbook in JSON or YAML. You can use the `AWS-UpdateLinuxAmi` runbook to perform the following types of tasks.

- Upgrade all distribution packages and Amazon software on an Amazon Linux, Red Hat Enterprise Linux, Ubuntu Server, SLES, or Cent OS Amazon Machine Image (AMI). This is the default runbook behavior.

- Install AWS Systems Manager SSM Agent on an existing image to enable Systems Manager capabilities, such as running remote commands using AWS Systems Manager Run Command or software inventory collection using Inventory.
- Install additional software packages.

## Before you begin

Before you begin working with runbooks, configure roles and, optionally, EventBridge for Automation. For more information, see [Setting up Automation](#). This walkthrough also requires that you specify the name of an AWS Identity and Access Management (IAM) instance profile. For more information about creating an IAM instance profile, see [Configure instance permissions required for Systems Manager](#).

The AWS-UpdateLinuxAmi runbook accepts the following input parameters.

| Parameter              | Type   | Description  |
|------------------------|--------|--|
| SourceAmild            | String | (Required) The source AMI ID. You can automatically reference the latest ID of an Amazon EC2 AMI for Linux by using a AWS Systems Manager Parameter Store <i>public</i> parameter. For more information, see <a href="#">Query for the latest Amazon Linux AMI IDs using AWS Systems Manager Parameter Store</a> . |
| IamInstanceProfileName | String | (Required) The name of the IAM instance profile role you created in <a href="#">Configure instance permissions required for Systems Manager</a> . The instance profile role gives Automation permission to perform actions on your   |

| Parameter            | Type   | Description   |
|----------------------|--------|---|
|                      |        | instances, such as running commands or starting and stopping services. The runbook uses only the name of the instance profile role.   |
| AutomationAssumeRole | String | (Required) The name of the IAM service role you created in <a href="#">Setting up Automation</a> . The service role (also called an assume role) gives Automation permission to assume your IAM role and perform actions on your behalf. For example, the service role allows Automation to create a new AMI when running the <code>aws:createImage</code> action in a runbook. For this parameter, the complete ARN must be specified. |
| TargetAmiName        | String | (Optional) The name of the new AMI after it is created. The default name is a system-generated string that includes the source AMI ID, and the creation time and date.  |
| InstanceType         | String | (Optional) The type of instance to launch as the workspace host. Instance types vary by Region. The default type is <code>t2.micro</code> .   |

| Parameter        | Type   | Description   |
|------------------|--------|---|
| PreUpdateScript  | String | (Optional) URL of a script to run before updates are applied. Default ( <code>\\"none\\"</code> ) is to not run a script.                     |
| PostUpdateScript | String | (Optional) URL of a script to run after package updates are applied. Default ( <code>\\"none\\"</code> ) is to not run a script.              |
| IncludePackages  | String | (Optional) Only update these named packages. By default ( <code>\\"all\\"</code> ), all available updates are applied.                        |
| ExcludePackages  | String | (Optional) Names of packages to hold back from updates, under all conditions. By default ( <code>\\"none\\"</code> ), no package is excluded. |

## Automation Steps

The `AWS-UpdateLinuxAmi` runbook includes the following steps, by default.

### Step 1: `launchInstance` (`aws:runInstances` action)

This step launches an instance using Amazon Elastic Compute Cloud (Amazon EC2) user data and an IAM instance profile role. User data installs the appropriate SSM Agent, based on the operating system. Installing SSM Agent enables you to utilize Systems Manager capabilities such as Run Command, State Manager, and Inventory.

### Step 2: `updateOSSoftware` (`aws:runCommand` action)

This step runs the following commands on the launched instance:

- Downloads an update script from Amazon Simple Storage Service (Amazon S3).
- Runs an optional pre-update script.

- Updates distribution packages and Amazon software.
- Runs an optional post-update script.

The execution log is stored in the `/tmp` folder for the user to view later.

If you want to upgrade a specific set of packages, you can supply the list using the `IncludePackages` parameter. When provided, the system attempts to update only these packages and their dependencies. No other updates are performed. By default, when no *include* packages are specified, the program updates all available packages.

If you want to exclude upgrading a specific set of packages, you can supply the list to the `ExcludePackages` parameter. If provided, these packages remain at their current version, independent of any other options specified. By default, when no *exclude* packages are specified, no packages are excluded.

### Step 3: stopInstance (aws : changeInstanceState action)

This step stops the updated instance.

### Step 4: createImage (aws : createImage action)

This step creates a new AMI with a descriptive name that links it to the source ID and creation time. For example: "AMI Generated by EC2 Automation on `{{global:DATE_TIME}}` from `{{SourceAmild}}`" where `DATE_TIME` and `SourceID` represent Automation variables.

### Step 5: terminateInstance (aws : changeInstanceState action)

This step cleans up the automation by terminating the running instance.

## Output

The automation returns the new AMI ID as output.

### Note

By default, when Automation runs the `AWS-UpdateLinuxAmi` runbook, the system creates a temporary instance in the default VPC (172.30.0.0/16). If you deleted the default VPC, you will receive the following error:

```
VPC not defined 400
```

To solve this problem, you must make a copy of the `AWS-UpdateLinuxAmi` runbook and specify a subnet ID. For more information, see [VPC not defined 400](#).

## To create a patched AMI using Automation

1. Install and configure the AWS Command Line Interface (AWS CLI), if you haven't already.

For information, see [Installing or updating the latest version of the AWS CLI](#).

2. Run the following command to run the AWS-UpdateLinuxAmi runbook. Replace each *example resource placeholder* with your own information.

```
aws ssm start-automation-execution \  
  --document-name "AWS-UpdateLinuxAmi" \  
  --parameters \  
    SourceAmiId=AMI ID, \  
    IamInstanceProfileName=IAM instance profile, \  
    AutomationAssumeRole='arn:aws:iam::  
{{global:ACCOUNT_ID}}:role/AutomationServiceRole'
```

The command returns an execution ID. Copy this ID to the clipboard. You will use this ID to view the status of the automation.

```
{  
  "AutomationExecutionId": "automation execution ID"  
}
```

3. To view the automation using the AWS CLI, run the following command:

```
aws ssm describe-automation-executions
```

4. To view details about the automation progress, run the following command. Replace *automation execution ID* with your own information.

```
aws ssm get-automation-execution --automation-execution-id automation execution ID
```

The update process can take 30 minutes or more to complete.

### Note

You can also monitor the status of the automation in the console. In the list, choose the automation you just ran and then choose the **Steps** tab. This tab shows you the status of the automation actions.

After the automation finishes, launch a test instance from the updated AMI to verify changes.

### Note

If any step in the automation fails, information about the failure is listed on the **Automation Executions** page. The automation is designed to terminate the temporary instance after successfully completing all tasks. If a step fails, the system might not terminate the instance. So if a step fails, manually terminate the temporary instance.

## Update a Windows Server AMI

The `AWS-UpdateWindowsAmi` runbook enables you to automate image maintenance tasks on your Amazon Windows Amazon Machine Image (AMI) without having to author the runbook in JSON or YAML. This runbook is supported for Windows Server 2008 R2 or later. You can use the `AWS-UpdateWindowsAmi` runbook to perform the following types of tasks.

- Install all Windows updates and upgrade Amazon software (default behavior).
- Install specific Windows updates and upgrade Amazon software.
- Customize an AMI using your scripts.

### Before you begin

Before you begin working with runbooks, [configure roles for Automation](#) to add an `iam:PassRole` policy that references the ARN of the instance profile you want to grant access to. Optionally, configure Amazon EventBridge for Automation, a capability of AWS Systems Manager. For more information, see [Setting up Automation](#). This walkthrough also requires that you specify the name of an AWS Identity and Access Management (IAM) instance profile. For more information about creating an IAM instance profile, see [Configure instance permissions required for Systems Manager](#).

### Note

Updates to AWS Systems Manager SSM Agent are typically rolled out to different regions at different times. When you customize or update an AMI, use only source AMIs published for the region that you are working in. This will ensure that you are working with the latest SSM Agent released for that region and avoid compatibility issues.

The AWS-UpdateWindowsAmi runbook accepts the following input parameters.

| Parameter              | Type   | Description  |
|------------------------|--------|--|
| SourceAmiId            | String | (Required) The source AMI ID. You can automatically reference the latest Windows Server AMI ID by using a Systems Manager Parameter Store <i>public</i> parameter. For more information, see <a href="#">Query for the latest Windows AMI IDs using AWS Systems Manager Parameter Store</a> .  |
| SubnetId               | String | (Optional) The subnet you want to launch the temporary instance into. You must specify a value for this parameter if you've deleted your default VPC.  |
| IamInstanceProfileName | String | (Required) The name of the IAM instance profile role you created in <a href="#">Configure instance permissions required for Systems Manager</a> . The instance profile role gives Automation permission to perform actions on your instances, such as running commands or starting and stopping services. The runbook uses only the name of the instance profile role. |
| AutomationAssumeRole   | String | (Required) The name of the IAM service role you created  |

| Parameter        | Type   | Description   |
|------------------|--------|---|
|                  |        | in <a href="#">Setting up Automation</a> . The service role (also called an assume role) gives Automation permission to assume your IAM role and perform actions on your behalf. For example, the service role allows Automation to create a new AMI when running the <code>aws:createImage</code> action in a runbook. For this parameter, the complete ARN must be specified. |
| TargetAmiName    | String | (Optional) The name of the new AMI after it is created. The default name is a system-generated string that includes the source AMI ID, and the creation time and date.  |
| InstanceType     | String | (Optional) The type of instance to launch as the workspace host. Instance types vary by region. The default type is <code>t2.medium</code> .  |
| PreUpdateScript  | String | (Optional) A script to run before updating the AMI. Enter a script in the runbook or at runtime as a parameter.   |
| PostUpdateScript | String | (Optional) A script to run after updating the AMI. Enter a script in the runbook or at runtime as a parameter.  |

| Parameter  | Type   | Description  |
|------------|--------|--|
| IncludeKbs | String | (Optional) Specify one or more Microsoft Knowledge Base (KB) article IDs to include. You can install multiple IDs using comma-separated values. Valid formats: KB9876543 or 9876543.   |
| ExcludeKbs | String | (Optional) Specify one or more Microsoft Knowledge Base (KB) article IDs to exclude. You can exclude multiple IDs using comma-separated values. Valid formats: KB9876543 or 9876543.   |
| Categories | String | (Optional) Specify one or more update categories. You can filter categories using comma-separated values. Options: Critical Update, Security Update, Definition Update, Update Rollup, Service Pack, Tool, Update, or Driver. Valid formats include a single entry, for example: Critical Update. Or, you can specify a comma-separated list: Critical Update, Security Update, Definition Update. |

| Parameter      | Type   | Description  |
|----------------|--------|--|
| SeverityLevels | String | (Optional) Specify one or more MSRC severity levels associated with an update. You can filter severity levels using comma-separated values. Options: Critical, Important, Low, Moderate or Unspecified. Valid formats include a single entry, for example: Critical. Or, you can specify a comma separated list: Critical,Important,Low. |

## Automation Steps

The `AWS-UpdateWindowsAmi` runbook includes the following steps, by default.

### Step 1: `launchInstance` (`aws:runInstances` action)

This step launches an instance with an IAM instance profile role from the specified `SourceAmiID`.

### Step 2: `runPreUpdateScript` (`aws:runCommand` action)

This step enables you to specify a script as a string that runs before updates are installed.

### Step 3: `updateEC2Config` (`aws:runCommand` action)

This step uses the `AWS-InstallPowerShellModule` runbook to download an AWS public PowerShell module. Systems Manager verifies the integrity of the module by using an SHA-256 hash. Systems Manager then checks the operating system to determine whether to update `EC2Config` or `EC2Launch`. `EC2Config` runs on Windows Server 2008 R2 through Windows Server 2012 R2. `EC2Launch` runs on Windows Server 2016.

### Step 4: `updateSSMAgent` (`aws:runCommand` action)

This step updates SSM Agent by using the `AWS-UpdateSSMAgent` runbook.

**Step 5: updateAWSPVDriver (aws : runCommand action)**

This step updates AWS PV drivers by using the AWS-ConfigureAWSPackage runbook.

**Step 6: updateAwsEnaNetworkDriver (aws : runCommand action)**

This step updates AWS ENA Network drivers by using the AWS-ConfigureAWSPackage runbook.

**Step 7: installWindowsUpdates (aws : runCommand action)**

This step installs Windows updates by using the AWS-InstallWindowsUpdates runbook. By default, Systems Manager searches for and installs all missing updates. You can change the default behavior by specifying one of the following parameters: IncludeKbs, ExcludeKbs, Categories, or SeverityLevels.

**Step 8: runPostUpdateScript (aws : runCommand action)**

This step enables you to specify a script as a string that runs after the updates have been installed.

**Step 9: runSysprepGeneralize (aws : runCommand action)**

This step uses the AWS-InstallPowerShellModule runbook to download an AWS public PowerShell module. Systems Manager verifies the integrity of the module by using an SHA-256 hash. Systems Manager then runs sysprep using AWS-supported methods for either EC2Launch (Windows Server 2016) or EC2Config (Windows Server 2008 R2 through 2012 R2).

**Step 10: stopInstance (aws : changeInstanceState action)**

This step stops the updated instance.

**Step 11: createImage (aws : createImage action)**

This step creates a new AMI with a descriptive name that links it to the source ID and creation time. For example: "AMI Generated by EC2 Automation on {{global:DATE\_TIME}} from {{SourceAmild}}" where DATE\_TIME and SourceID represent Automation variables.

**Step 12: TerminateInstance (aws : changeInstanceState action)**

This step cleans up the automation by terminating the running instance.

**Output**

This section enables you to designate the outputs of various steps or values of any parameter as the Automation output. By default, the output is the ID of the updated Windows AMI created by the automation.

**Note**

By default, when Automation runs the `AWS-UpdateWindowsAmi` runbook and creates a temporary instance, the system uses the default VPC (172.30.0.0/16). If you deleted the default VPC, you will receive the following error:

VPC not defined 400

To solve this problem, you must make a copy of the `AWS-UpdateWindowsAmi` runbook and specify a subnet ID. For more information, see [VPC not defined 400](#).

**To create a patched Windows AMI by using Automation**

1. Install and configure the AWS Command Line Interface (AWS CLI), if you haven't already.

For information, see [Installing or updating the latest version of the AWS CLI](#).

2. Run the following command to run the `AWS-UpdateWindowsAmi` runbook. Replace each *example resource placeholder* with your own information. The example command below uses a recent Amazon EC2 AMI to minimize the number of patches that need to be applied. If you run this command more than once, you must specify a unique value for `targetAMIname`. AMI names must be unique.

```
aws ssm start-automation-execution \  
  --document-name="AWS-UpdateWindowsAmi" \  
  --parameters SourceAmiId='AMI ID',IamInstanceProfileName='IAM  
  instance profile',AutomationAssumeRole='arn:aws:iam::  
  {{global:ACCOUNT_ID}}:role/AutomationServiceRole'
```

The command returns an execution ID. Copy this ID to the clipboard. You will use this ID to view the status of the automation.

```
{  
  "AutomationExecutionId": "automation execution ID"  
}
```

3. To view the automation using the AWS CLI, run the following command:

```
aws ssm describe-automation-executions
```

4. To view details about the automation progress, run the following command.

```
aws ssm get-automation-execution
  --automation-execution-id automation execution ID
```

**Note**

Depending on the number of patches applied, the Windows patching process run in this sample automation can take 30 minutes or more to complete.

## Update a golden AMI using Automation, AWS Lambda, and Parameter Store

The following example uses the model where an organization maintains and periodically patches their own, proprietary AMIs rather than building from Amazon Elastic Compute Cloud (Amazon EC2) AMIs.

The following procedure shows how to automatically apply operating system (OS) patches to an AMI that is already considered to be the most up-to-date or *latest* AMI. In the example, the default value of the parameter `SourceAmiId` is defined by a AWS Systems Manager Parameter Store parameter called `latestAmi`. The value of `latestAmi` is updated by an AWS Lambda function invoked at the end of the automation. As a result of this Automation process, the time and effort spent patching AMIs is minimized because patching is always applied to the most up-to-date AMI. Parameter Store and Automation are capabilities of AWS Systems Manager.

### Before you begin

Configure Automation roles and, optionally, Amazon EventBridge for Automation. For more information, see [Setting up Automation](#).

### Contents

- [Task 1: Create a parameter in Systems Manager Parameter Store](#)
- [Task 2: Create an IAM role for AWS Lambda](#)
- [Task 3: Create an AWS Lambda function](#)
- [Task 4: Create a runbook and patch the AMI](#)

## Task 1: Create a parameter in Systems Manager Parameter Store

Create a string parameter in Parameter Store that uses the following information:

- **Name:** latestAmi.
- **Value:** An AMI ID. For example: ami-188d6e0e.

For information about how to create a Parameter Store string parameter, see [Creating Parameter Store parameters in Systems Manager](#).

## Task 2: Create an IAM role for AWS Lambda

Use the following procedure to create an IAM service role for AWS Lambda. These policies give Lambda permission to update the value of the latestAmi parameter using a Lambda function and Systems Manager.

### To create an IAM service role for Lambda

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **Policies**, and then choose **Create policy**.
3. Choose the **JSON** tab.
4. Replace the default contents with the following policy. Replace each *example resource placeholder* with your own information.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "logs:CreateLogGroup",
      "Resource": "arn:aws:logs:region:123456789012:*"
    },
    {
      "Effect": "Allow",
      "Action": [
        "logs:CreateLogStream",
        "logs:PutLogEvents"
      ],
      "Resource": [
        "arn:aws:logs:region:123456789012:log-group:/aws/lambda/function
name:*"
      ]
    }
  ]
}
```

```
]
}
```

5. Choose **Next: Tags**.
6. (Optional) Add one or more tag-key value pairs to organize, track, or control access for this policy.
7. Choose **Next: Review**.
8. On the **Review policy** page, for **Name**, enter a name for the inline policy, such as **amiLambda**.
9. Choose **Create policy**.
10. Repeat steps 2 and 3.
11. Paste the following policy. Replace each *example resource placeholder* with your own information.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "ssm:PutParameter",
      "Resource": "arn:aws:ssm:region:123456789012:parameter/latestAmi"
    },
    {
      "Effect": "Allow",
      "Action": "ssm:DescribeParameters",
      "Resource": "*"
    }
  ]
}
```

12. Choose **Next: Tags**.
13. (Optional) Add one or more tag-key value pairs to organize, track, or control access for this policy.
14. Choose **Next: Review**.
15. On the **Review policy** page, for **Name**, enter a name for the inline policy, such as **amiParameter**.
16. Choose **Create policy**.
17. In the navigation pane, choose **Roles**, and then choose **Create role**.
18. Immediately under **Use case**, choose **Lambda**, and then choose **Next**.

19. On the **Add permissions** page, use the **Search** field to locate the two policies you created earlier.
20. Select the check box next to the policies, and then choose **Next**.
21. For **Role name**, enter a name for your new role, such as **lambda-ssm-role** or another name that you prefer.

 **Note**

Because various entities might reference the role, you cannot change the name of the role after it has been created.

22. (Optional) Add one or more tag key-value pairs to organize, track, or control access for this role, and then choose **Create role**.

### Task 3: Create an AWS Lambda function

Use the following procedure to create a Lambda function that automatically updates the value of the `latestAmi` parameter.

#### To create a Lambda function

1. Sign in to the AWS Management Console and open the AWS Lambda console at <https://console.aws.amazon.com/lambda/>.
2. Choose **Create function**.
3. On the **Create function** page, choose **Author from scratch**.
4. For **Function name**, enter **Automation-UpdateSsmParam**.
5. For **Runtime**, choose **Python 3.8**.
6. For **Architecture**, select the type of computer processor for Lambda to use to run the function, **x86\_64** or **arm64**,
7. In the **Permissions** section, expand **Change default execution role**.
8. Choose **Use an existing role**, and then choose the service role for Lambda that you created in Task 2.
9. Choose **Create function**.
10. In the **Code source** area, on the **lambda\_function** tab, delete the pre-populated code in the field, and then paste the following code sample.

```
from __future__ import print_function

import json
import boto3

print('Loading function')

#Updates an SSM parameter
#Expects parameterName, parameterValue
def lambda_handler(event, context):
    print("Received event: " + json.dumps(event, indent=2))

    # get SSM client
    client = boto3.client('ssm')

    #confirm parameter exists before updating it
    response = client.describe_parameters(
        Filters=[
            {
                'Key': 'Name',
                'Values': [ event['parameterName'] ]
            },
        ]
    )

    if not response['Parameters']:
        print('No such parameter')
        return 'SSM parameter not found.'

    #if parameter has a Description field, update it PLUS the Value
    if 'Description' in response['Parameters'][0]:
        description = response['Parameters'][0]['Description']

        response = client.put_parameter(
            Name=event['parameterName'],
            Value=event['parameterValue'],
            Description=description,
            Type='String',
            Overwrite=True
        )

    #otherwise just update Value
```

```
else:
    response = client.put_parameter(
        Name=event['parameterName'],
        Value=event['parameterValue'],
        Type='String',
        Overwrite=True
    )

    responseString = 'Updated parameter %s with value %s.' %
(event['parameterName'], event['parameterValue'])

    return responseString
```

11. Choose **File, Save**.
12. To test the Lambda function, from the **Test** menu, choose **Configure test event**.
13. For **Event name**, enter a name for the test event, such as **MyTestEvent**.
14. Replace the existing text with the following JSON. Replace **AMI ID** with your own information to set your `latestAmi` parameter value.

```
{
  "parameterName": "latestAmi",
  "parameterValue": "AMI ID"
}
```

15. Choose **Save**.
16. Choose **Test** to test the function. On the **Execution result** tab, the status should be reported as **Succeeded**, along with other details about the update.

#### Task 4: Create a runbook and patch the AMI

Use the following procedure to create and run a runbook that patches the AMI you specified for the `latestAmi` parameter. After the automation completes, the value of `latestAmi` is updated with the ID of the newly-patched AMI. Subsequent automations use the AMI created by the previous execution.

##### To create and run the runbook

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Documents**.

3. For **Create document**, choose **Automation**.
4. For **Name**, enter **UpdateMyLatestWindowsAmi**.
5. Choose the **Editor** tab, and then choose **Edit**.
6. Choose **OK** when prompted.
7. In the **Document editor** field, replace the default content with the following YAML sample runbook content.

```
---
description: Systems Manager Automation Demo - Patch AMI and Update ASG
schemaVersion: '0.3'
assumeRole: '{{ AutomationAssumeRole }}'
parameters:
  AutomationAssumeRole:
    type: String
    description: '(Required) The ARN of the role that allows Automation to perform
the actions on your behalf. If no role is specified, Systems Manager Automation
uses your IAM permissions to execute this document.'

outputs:
- createImage.ImageId
```

8. Choose **Create automation**.
9. In the navigation pane, choose **Automation**, and then choose **Execute automation**.
10. In the **Choose document** page, choose the **Owned by me** tab.
11. Search for the **UpdateMyLatestWindowsAmi** runbook, and select the button in the **UpdateMyLatestWindowsAmi** card.
12. Choose **Next**.
13. Choose **Simple execution**.
14. Specify values for the input parameters.
15. Choose **Execute**.
16. After the automation completes, choose **Parameter Store** in the navigation pane and confirm that the new value for `latestAmi` matches the value returned by the automation. You can also verify the new AMI ID matches the Automation output in the **AMIs** section of the Amazon EC2 console.

## Updating AMIs using Automation and Jenkins

If your organization uses Jenkins software in a CI/CD pipeline, you can add Automation as a post-build step to pre-install application releases into Amazon Machine Images (AMIs). Automation is a capability of AWS Systems Manager. You can also use the Jenkins scheduling feature to call Automation and create your own operating system (OS) patching cadence.

The example below shows how to invoke Automation from a Jenkins server that is running either on-premises or in Amazon Elastic Compute Cloud (Amazon EC2). For authentication, the Jenkins server uses AWS credentials based on an IAM policy that you create in the example and attach to your instance profile.

**Note**

Be sure to follow Jenkins security best practices when configuring your instance.

**Before you begin**

Complete the following tasks before you configure Automation with Jenkins:

- Complete the [Update a golden AMI using Automation, AWS Lambda, and Parameter Store](#) example. The following example uses the **UpdateMyLatestWindowsAmi** runbook created in that example.
- Configure IAM roles for Automation. Systems Manager requires an instance profile role and a service role ARN to process automations. For more information, see [Setting up Automation](#).

**To create an IAM policy for the Jenkins server**

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **Policies**, and then choose **Create policy**.
3. Choose the **JSON** tab.
4. Replace each *example resource placeholder* with your own information.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "ssm:StartAutomationExecution",
      "Resource": [
        "arn:aws:ssm:region:account ID:document/
UpdateMyLatestWindowsAmi",
        "arn:aws:ssm:region:account ID:automation-definition/
UpdateMyLatestWindowsAmi:$DEFAULT"
      ]
    }
  ]
}
```

5. Choose **Review policy**.
6. On the **Review policy** page, for **Name**, enter a name for the inline policy, such as **JenkinsPolicy**.
7. Choose **Create policy**.
8. In the navigation pane, choose **Roles**.
9. Choose the instance profile that's attached to your Jenkins server.
10. In the **Permissions** tab, select **Add permissions** and choose **Attach policies**.
11. In the **Other permissions policies** section, enter the name of policy you created in the previous steps. For example, **JenkinsPolicy**.
12. Select the check box next to your policy, and choose **Attach policies**.

Use the following procedure to configure the AWS CLI on your Jenkins server.

### To configure the Jenkins server for Automation

1. Connect to your Jenkins server on port 8080 using your preferred browser to access the management interface.
2. Enter the password found in `/var/lib/jenkins/secrets/initialAdminPassword`. To display your password, run the following command.

```
sudo cat /var/lib/jenkins/secrets/initialAdminPassword
```

3. The Jenkins installation script directs you to the **Customize Jenkins** page. Select **Install suggested plugins**.
4. Once the installation is complete, choose **Administrator Credentials**, select **Save Credentials**, and then select **Start Using Jenkins**.
5. In the left navigation pane, choose **Manage Jenkins**, and then choose **Manage Plugins**.
6. Choose the **Available** tab, and then enter **Amazon EC2 plugin**.
7. Select the check box for **Amazon EC2 plugin**, and then select **Install without restart**.
8. When the installation completes, select **Go back to the top page**.
9. Choose **Manage Jenkins**, and then choose **Manage nodes and clouds**.
10. In the **Configure Clouds** section, select **Add a new cloud**, and then choose **Amazon EC2**.
11. Enter your information in the remaining fields. Make sure you select the **Use EC2 instance profile to obtain credentials** option.

Use the following procedure to configure your Jenkins project to invoke Automation.

### To configure your Jenkins server to invoke Automation

1. Open the Jenkins console in a web browser.
2. Choose the project that you want to configure with Automation, and then choose **Configure**.
3. On the **Build** tab, choose **Add Build Step**.
4. Choose **Execute shell** or **Execute Windows batch command** (depending on your operating system).
5. In the **Command** field, run an AWS CLI command like the following. Replace each *example resource placeholder* with your own information.

```
aws ssm start-automation-execution \  
    --document-name runbook name \  
    --region AWS Region of your source AMI \  
    --parameters runbook parameters
```

The following example command uses the **UpdateMyLatestWindowsAmi** runbook and the Systems Manager Parameter `latestAmi` created in [Update a golden AMI using Automation, AWS Lambda, and Parameter Store](#).

```
aws ssm start-automation-execution \  
    --document-name UpdateMyLatestWindowsAmi \  
    --parameters \  
        "sourceAMIid='{{ssm:latestAmi}}'" \  
    --region region
```

In Jenkins, the command looks like the example in the following screenshot.

6. In the Jenkins project, choose **Build Now**. Jenkins returns output similar to the following example.

### Console Output

```
Started by user admin
Building in workspace /var/lib/jenkins/workspace/Build AMI
[Build AMI] $ /bin/sh -xe /tmp/hudson3259912997441414819.sh
+ aws --region us-east-1 ssm start-automation-execution --document-name UpdateMyLatestWindowsAmi --parameters 'sourceAMIid='\${ssm:latestAmi}\''
{
  "AutomationExecutionId": "7badf13a-ff8c-11e6-9503-9d48daa849f3"
}
Finished: SUCCESS
```

## Updating AMIs for Auto Scaling groups

The following example updates an Auto Scaling group with a newly patched AMI. This approach ensures that new images are automatically made available to different computing environments that use Auto Scaling groups.

The final step of the automation in this example uses a Python function to create a new launch template that uses the newly patched AMI. Then the Auto Scaling group is updated to use the new launch template. In this type of Auto Scaling scenario, users could terminate existing instances in the Auto Scaling group to force a new instance to launch that uses the new image. Or, users could wait and allow scale-in or scale-out events to naturally launch newer instances.

### Before you begin

Complete the following tasks before you begin this example.

- Configure IAM roles for Automation, a capability of AWS Systems Manager. Systems Manager requires an instance profile role and a service role ARN to process automations. For more information, see [Setting up Automation](#).

## Create the PatchAMIAndUpdateASG runbook

Use the following procedure to create the **PatchAMIAndUpdateASG** runbook that patches the AMI you specify for the **SourceAMI** parameter. The runbook also updates an Auto Scaling group to use the latest, patched AMI.

### To create and run the runbook

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Documents**.
3. In the **Create document** dropdown, choose **Automation**.
4. In the **Name** field, enter **PatchAMIAndUpdateASG**.
5. Choose the **Editor** tab, and choose the **Edit**.
6. Choose **OK** when prompted, and delete the content in the **Document editor** field.
7. In the **Document editor** field, paste the following YAML sample runbook content.

```
---
description: Systems Manager Automation Demo - Patch AMI and Update ASG
schemaVersion: '0.3'
assumeRole: '{{ AutomationAssumeRole }}'
parameters:
  AutomationAssumeRole:
    type: String
    description: '(Required) The ARN of the role that allows Automation to perform the actions on your behalf. If no role is specified, Systems Manager Automation uses your IAM permissions to execute this document.'
    default: ''
  SourceAMI:
    type: String
    description: '(Required) The ID of the AMI you want to patch.'
  SubnetId:
    type: String
    description: '(Required) The ID of the subnet where the instance from the SourceAMI parameter is launched.'
```

```
SecurityGroupIds:
  type: StringList
  description: '(Required) The IDs of the security groups to associate with the
instance launched from the SourceAMI parameter.'
NewAMI:
  type: String
  description: '(Optional) The name of of newly patched AMI.'
  default: 'patchedAMI-{{global:DATE_TIME}}'
TargetASG:
  type: String
  description: '(Required) The name of the Auto Scaling group you want to
update.'
InstanceProfile:
  type: String
  description: '(Required) The name of the IAM instance profile you want the
source instance to use.'
SnapshotId:
  type: String
  description: '(Optional) The snapshot ID to use to retrieve a patch baseline
snapshot.'
  default: ''
RebootOption:
  type: String
  description: '(Optional) Reboot behavior after a patch Install operation. If
you choose NoReboot and patches are installed, the instance is marked as non-
compliant until a subsequent reboot and scan.'
  allowedValues:
    - NoReboot
    - RebootIfNeeded
  default: RebootIfNeeded
Operation:
  type: String
  description: '(Optional) The update or configuration to perform on the instance.
The system checks if patches specified in the patch baseline are installed on the
instance. The install operation installs patches missing from the baseline.'
  allowedValues:
    - Install
    - Scan
  default: Install
mainSteps:
  - name: startInstances
    action: 'aws:runInstances'
    timeoutSeconds: 1200
    maxAttempts: 1
```

```
onFailure: Abort
inputs:

    # create auto scaling and ec2 client
    asg = boto3.client('autoscaling')
    ec2 = boto3.client('ec2')

    def update_asg(event, context):
        print("Received event: " + json.dumps(event, indent=2))

        target_asg = event['TargetASG']
        new_ami = event['NewAMI']
```

```

        # get object for the ASG we're going to update, filter by name of
target ASG
        asg_query =
asg.describe_auto_scaling_groups(AutoScalingGroupNames=[target_asg])
        if 'AutoScalingGroups' not in asg_query or not
asg_query['AutoScalingGroups']:
            return 'No ASG found matching the value you specified.'

        # gets details of an instance from the ASG that we'll use to model the
new launch template after
        source_instance_id = asg_query.get('AutoScalingGroups')[0]['Instances']
[0]['InstanceId']
        instance_properties = ec2.describe_instances(
            InstanceIds=[source_instance_id]
        )
        source_instance = instance_properties['Reservations'][0]['Instances']
[0]

        # create list of security group IDs
security_groups = []
        for group in source_instance['SecurityGroups']:
            security_groups.append(group['GroupId'])

        # create a list of dictionary objects for block device mappings
mappings = []
        for block in source_instance['BlockDeviceMappings']:
            volume_query = ec2.describe_volumes(
                VolumeIds=[block['Ebs']['VolumeId']]
            )
            volume_details = volume_query['Volumes']
            device_name = block['DeviceName']
            volume_size = volume_details[0]['Size']
            volume_type = volume_details[0]['VolumeType']
            device = {'DeviceName': device_name, 'Ebs': {'VolumeSize':
volume_size, 'VolumeType': volume_type}}
            mappings.append(device)

        # create new launch template using details returned from instance in
the ASG and specify the newly patched AMI
        time_stamp = time.time()
        time_stamp_string =
datetime.datetime.fromtimestamp(time_stamp).strftime('%m-%d-%Y_%H-%M-%S')
        new_template_name = f'{new_ami}_{time_stamp_string}'
        try:

```

```
    ec2.create_launch_template(
        LaunchTemplateName=new_template_name,
        LaunchTemplateData={
            'BlockDeviceMappings': mappings,
            'ImageId': new_ami,
            'InstanceType': source_instance['InstanceType'],
            'IamInstanceProfile': {
                'Arn': source_instance['IamInstanceProfile']['Arn']
            },
            'KeyName': source_instance['KeyName'],
            'SecurityGroupIds': security_groups
        }
    )
except Exception as e:
    return f'Exception caught: {str(e)}'
else:
    # update ASG to use new launch template
    asg.update_auto_scaling_group(
        AutoScalingGroupName=target_asg,
        LaunchTemplate={
            'LaunchTemplateName': new_template_name
        }
    )
    return f'Updated ASG {target_asg} with new launch template
    {new_template_name} which uses AMI {new_ami}.'
outputs:
    - createImage.ImageId
```

8. Choose **Create automation**.
9. In the navigation pane, choose **Automation**, and then choose **Execute automation**.
10. In the **Choose document** page, choose the **Owned by me** tab.
11. Search for the **PatchAMIAndUpdateASG** runbook, and select the button in the **PatchAMIAndUpdateASG** card.
12. Choose **Next**.
13. Choose **Simple execution**.
14. Specify values for the input parameters. Be sure the SubnetId and SecurityGroupIds you specify allow access to the public Systems Manager endpoints, or your interface endpoints for Systems Manager.
15. Choose **Execute**.

16. After automation completes, in the Amazon EC2 console, choose **Auto Scaling**, and then choose **Launch Templates**. Verify that you see the new launch template, and that it uses the new AMI.
17. Choose **Auto Scaling**, and then choose **Auto Scaling Groups**. Verify that the Auto Scaling group uses the new launch template.
18. Terminate one or more instances in your Auto Scaling group. Replacement instances will be launched using the new AMI.

## Using AWS Support self-service runbooks

This section describes how to use some of the self-service automations created by the AWS Support team. These automations help you manage your AWS resources.

### Support Automation Workflows

Support Automation Workflows (SAW) are automation runbooks written and maintained by the AWS Support team. These runbooks help you troubleshoot common issues with your AWS resources, proactively monitor and identify network issues, collect and analyze logs, and more.

SAW runbooks use the **AWSSupport** prefix. For example, [AWSSupport-ActivateWindowsWithAmazonLicense](#).

Additionally, AWS Enterprise and Business Support customers also have access to runbooks that use the **AWSPremiumSupport** prefix. For example, [AWSPremiumSupport-TroubleshootEC2DiskUsage](#).

To learn more about AWS Support, see [Getting started with AWS Support](#).

### Topics

- [Run the EC2Rescue tool on unreachable instances](#)
- [Reset passwords and SSH keys on EC2 instances](#)

### Run the EC2Rescue tool on unreachable instances

EC2Rescue can help you diagnose and troubleshoot problems on Amazon Elastic Compute Cloud (Amazon EC2) instances for Linux and Windows Server. You can run the tool manually, as described in [Using EC2Rescue for Linux Server](#) and [Using EC2Rescue for Windows Server](#). Or, you can run the tool automatically by using Systems Manager Automation and the **AWSSupport-ExecuteEC2Rescue** runbook. Automation is a capability of AWS Systems Manager. The

**AWSupport-ExecuteEC2Rescue** runbook is designed to perform a combination of Systems Manager actions, AWS CloudFormation actions, and Lambda functions that automate the steps normally required to use EC2Rescue.

You can use the **AWSupport-ExecuteEC2Rescue** runbook to troubleshoot and potentially remediate different types of operating system (OS) issues. Instances with encrypted root volumes are not supported. See the following topics for a complete list:

**Windows:** See *Rescue Action* in [Using EC2Rescue for Windows Server with the Command Line](#).

**Linux and macOS:** Some EC2Rescue for Linux modules detect and attempt to remediate issues. For more information, see the [aws-ec2rescue-linux](#) documentation for each module on GitHub.

## How it works

Troubleshooting an instance with Automation and the **AWSupport-ExecuteEC2Rescue** runbook works as follows:

- You specify the ID of the unreachable instance and start the runbook.
- The system creates a temporary VPC, and then runs a series of Lambda functions to configure the VPC.
- The system identifies a subnet for your temporary VPC in the same Availability Zone as your original instance.
- The system launches a temporary, SSM-enabled helper instance.
- The system stops your original instance, and creates a backup. It then attaches the original root volume to the helper instance.
- The system uses Run Command to run EC2Rescue on the helper instance. EC2Rescue identifies and attempts to fix issues on the attached, original root volume. When finished, EC2Rescue reattaches the root volume back to the original instance.
- The system restarts your original instance, and terminates the temporary instance. The system also terminates the temporary VPC and the Lambda functions created at the start of the automation.

## Before you begin

Before you run the following Automation, do the following:

- Copy the instance ID of the unreachable instance. You will specify this ID in the procedure.

- Optionally, collect the ID of a subnet in the same availability zone as your unreachable instance. The EC2Rescue instance will be created in this subnet. If you don't specify a subnet, then Automation creates a new temporary VPC in your AWS account. Verify that your AWS account has at least one VPC available. By default, you can create five VPCs in a Region. If you already created five VPCs in the Region, the automation fails without making changes to your instance. For more information about Amazon VPC quotas, see [VPC and Subnets](#) in the *Amazon VPC User Guide*.
- Optionally, you can create and specify an AWS Identity and Access Management (IAM) role for Automation. If you don't specify this role, then Automation runs in the context of the user who ran the automation.

### Granting AWSSupport -EC2Rescue permissions to perform actions on your instances

EC2Rescue needs permission to perform a series of actions on your instances during the automation. These actions invoke the AWS Lambda, IAM, and Amazon EC2 services to safely and securely attempt to remediate issues with your instances. If you have Administrator-level permissions in your AWS account and/or VPC, you might be able to run the automation without configuring permissions, as described in this section. If you don't have Administrator-level permissions, then you or an administrator must configure permissions by using one of the following options.

- [Granting permissions by using IAM policies](#)
- [Granting permissions by using an AWS CloudFormation template](#)

#### Granting permissions by using IAM policies

You can either attach the following IAM policy to your user, group, or role as an inline policy; or, you can create a new IAM managed policy and attach it to your user, group, or role. For more information about adding an inline policy to your user, group, or role see [Working With Inline Policies](#). For more information about creating a new managed policy, see [Working With Managed Policies](#).

**Note**

If you create a new IAM managed policy, you must also attach the **AmazonSSMAutomationRole** managed policy to it so that your instances can communicate with the Systems Manager API.

## IAM Policy for AWSSupport-EC2Rescue

Replace *account ID* with your own information.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Action": [
        "lambda:InvokeFunction",
        "lambda>DeleteFunction",
        "lambda:GetFunction"
      ],
      "Resource": "arn:aws:lambda:*:account ID:function:AWSSupport-EC2Rescue-*",
      "Effect": "Allow"
    },
    {
      "Action": [
        "s3:GetObject",
        "s3:GetObjectVersion"
      ],
      "Resource": [
        "arn:aws:s3:::awssupport-ssm.*/*.template",
        "arn:aws:s3:::awssupport-ssm.*/*.zip"
      ],
      "Effect": "Allow"
    },
    {
      "Action": [
        "iam:CreateRole",
        "iam:CreateInstanceProfile",
        "iam:GetRole",
        "iam:GetInstanceProfile",
        "iam:PutRolePolicy",
        "iam:DetachRolePolicy",
```

```

        "iam:AttachRolePolicy",
        "iam:PassRole",
        "iam:AddRoleToInstanceProfile",
        "iam:RemoveRoleFromInstanceProfile",
        "iam>DeleteRole",
        "iam>DeleteRolePolicy",
        "iam>DeleteInstanceProfile"
    ],
    "Resource": [
        "arn:aws:iam::account ID:role/AWSSupport-EC2Rescue-*",
        "arn:aws:iam::account ID:instance-profile/AWSSupport-EC2Rescue-*"
    ],
    "Effect": "Allow"
},
{
    "Action": [
        "lambda:CreateFunction",
        "ec2:CreateVpc",
        "ec2:ModifyVpcAttribute",
        "ec2>DeleteVpc",
        "ec2:CreateInternetGateway",
        "ec2:AttachInternetGateway",
        "ec2:DetachInternetGateway",
        "ec2>DeleteInternetGateway",
        "ec2:CreateSubnet",
        "ec2>DeleteSubnet",
        "ec2:CreateRoute",
        "ec2>DeleteRoute",
        "ec2:CreateRouteTable",
        "ec2:AssociateRouteTable",
        "ec2:DisassociateRouteTable",
        "ec2>DeleteRouteTable",
        "ec2:CreateVpcEndpoint",
        "ec2>DeleteVpcEndpoints",
        "ec2:ModifyVpcEndpoint",
        "ec2:Describe*"
    ],
    "Resource": "*",
    "Effect": "Allow"
}
]
}

```

## Granting permissions by using an AWS CloudFormation template

AWS CloudFormation automates the process of creating IAM roles and policies by using a preconfigured template. Use the following procedure to create the required IAM roles and policies for the EC2Rescue Automation by using AWS CloudFormation.

### To create the required IAM roles and policies for EC2Rescue

1. Download [AWSSupport-EC2RescueRole.zip](#) and extract the `AWSSupport-EC2RescueRole.json` file to a directory on your local machine.
2. If your AWS account is in a special partition, edit the template to change the ARN values to those for your partition.

For example, for the China Regions, change all cases of `arn:aws` to `arn:aws-cn`.

3. Sign in to the AWS Management Console and open the AWS CloudFormation console at <https://console.aws.amazon.com/cloudformation>.
4. Choose **Create stack, With new resources (standard)**.
5. On the **Create stack** page, for **Prerequisite - Prepare template**, choose **Template is ready**.
6. For **Specify template**, choose **Upload a template file**.
7. Choose **Choose file**, and then browse to and select the `AWSSupport-EC2RescueRole.json` file from the directory where you extracted it.
8. Choose **Next**.
9. On the **Specify stack details** page, for **Stack name** field, enter a name to identify this stack, and then choose **Next**.
10. (Optional) In the **Tags** area, apply one or more tag key name/value pairs to the stack.

Tags are optional metadata that you assign to a resource. Tags enable you to categorize a resource in different ways, such as by purpose, owner, or environment. For example, you might want to tag a stack to identify the type of tasks it runs, the types of targets or other resources involved, and the environment it runs in.

11. Choose **Next**
12. On the **Review** page, review the stack details, and then scroll down and choose the **I acknowledge that AWS CloudFormation might create IAM resources** option.
13. Choose **Create stack**.

AWS CloudFormation shows the **CREATE\_IN\_PROGRESS** status for a few minutes. The status changes to **CREATE\_COMPLETE** after the stack has been created. You can also choose the refresh icon to check the status of the create process.

14. In the **Stacks** list, choose the option button the stack you just created, and then choose the **Outputs** tab.
15. Note the **Value**. This is the ARN of the AssumeRole. You specify this ARN when you run the Automation in the next procedure, [Running the Automation](#).

## Running the Automation

### Important

The following automation stops the unreachable instance. Stopping the instance can result in lost data on attached instance store volumes (if present). Stopping the instance can also cause the public IP to change, if no Elastic IP is associated.

## To run the **AWSSupport-ExecuteEC2Rescue** Automation

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Automation**.
3. Choose **Execute automation**.
4. In the **Automation document** section, choose **Owned by Amazon** from the list.
5. In the runbooks list, choose the button in the card for **AWSSupport-ExecuteEC2Rescue**, and then choose **Next**.
6. In the **Execute automation document** page, choose **Simple execution**.
7. In the **Document details** section, verify that **Document version** is set to the highest default version. For example, **\$DEFAULT** or **3 (default)**.
8. In the **Input parameters** section, specify the following parameters:
  - a. For **UnreachableInstanceId**, specify the ID of the unreachable instance.
  - b. (Optional) For **EC2RescueInstanceType**, specify an instance type for the EC2Rescue instance. The default instance type is `t2.medium`.

- c. For **AutomationAssumeRole**, if you created roles for this Automation by using the AWS CloudFormation procedure described earlier in this topic, then choose the ARN of the AssumeRole that you created in the AWS CloudFormation console.
- d. (Optional) For **LogDestination**, specify an S3 bucket if you want to collect operating system-level logs while troubleshooting your instance. Logs are automatically uploaded to the specified bucket.
- e. For **SubnetId**, specify a subnet in an existing VPC in the same availability zone as the unreachable instance. By default, Systems Manager creates a new VPC, but you can specify a subnet in an existing VPC if you want.

 **Note**

If you don't see the option to specify a bucket or a subnet ID, verify that you are using the latest **Default** version of the runbook.

9. (Optional) In the **Tags** area, apply one or more tag key name/value pairs to help identify the automation, for example `Key=Purpose, Value=EC2Rescue`.
10. Choose **Execute**.

The runbook creates a backup AMI as part of the automation. All other resources created by the automation are automatically deleted, but this AMI remains in your account. The AMI is named using the following convention:

Backup AMI: `AWSSupport-EC2Rescue:UnreachableInstanceId`

You can locate this AMI in the Amazon EC2 console by searching on the Automation execution ID.

## Reset passwords and SSH keys on EC2 instances

You can use the `AWSSupport-ResetAccess` runbook to automatically re-enable local Administrator password generation on Amazon Elastic Compute Cloud (Amazon EC2) instances for Windows Server and to generate a new SSH key on EC2 instances for Linux. The `AWSSupport-ResetAccess` runbook is designed to perform a combination of AWS Systems Manager actions, AWS CloudFormation actions, and AWS Lambda functions that automate the steps normally required to reset the local administrator password.

You can use Automation, a capability of AWS Systems Manager, with the `AWSSupport-ResetAccess` runbook to solve the following problems:

## Windows

*You lost the EC2 key pair:* To resolve this problem, you can use the **AWSSupport-ResetAccess** runbook to create a password-enabled AMI from your current instance, launch a new instance from the AMI, and select a key pair you own.

*You lost the local Administrator password:* To resolve this problem, you can use the **AWSSupport-ResetAccess** runbook to generate a new password that you can decrypt with the current EC2 key pair.

## Linux

*You lost your EC2 key pair, or you configured SSH access to the instance with a key you lost:* To resolve this problem, you can use the **AWSSupport-ResetAccess** runbook to create a new SSH key for your current instance, which enables you to connect to the instance again.

### Note

If your EC2 instance for Windows Server is configured for Systems Manager, you can also reset your local Administrator password by using **EC2Rescue** and **AWS Systems Manager Run Command**. For more information, see [Using EC2Rescue for Windows Server with Systems Manager Run Command](#) in the *Amazon EC2 User Guide*.

## Related information

[Connect to your Linux instance from Windows using PuTTY](#) in the *Amazon EC2 User Guide*

## How it works

Troubleshooting an instance with Automation and the **AWSSupport-ResetAccess** runbook works as follows:

- You specify the ID of the instance and run the runbook.
- The system creates a temporary VPC, and then runs a series of Lambda functions to configure the VPC.
- The system identifies a subnet for your temporary VPC in the same Availability Zone as your original instance.

- The system launches a temporary, SSM-enabled helper instance.
- The system stops your original instance, and creates a backup. It then attaches the original root volume to the helper instance.
- The system uses Run Command to run EC2Rescue on the helper instance. On Windows, EC2Rescue enables password generation for the local Administrator by using EC2Config or EC2Launch on the attached, original root volume. On Linux, EC2Rescue generates and injects a new SSH key and saves the private key, encrypted, in Parameter Store. When finished, EC2Rescue reattaches the root volume back to the original instance.
- The system creates a new Amazon Machine Image (AMI) of your instance, now that password generation is enabled. You can use this AMI to create a new EC2 instance, and associate a new key pair if needed.
- The system restarts your original instance, and terminates the temporary instance. The system also terminates the temporary VPC and the Lambda functions created at the start of the automation.
- **Windows:** Your instance generates a new password you can decode from the Amazon EC2 console using the current key pair assigned to the instance.

**Linux:** You can SSH to the instance by using the SSH key stored in Systems Manager Parameter Store as `/ec2rl/openssh/instance ID/key`.

## Before you begin

Before you run the following Automation, do the following:

- Copy the instance ID of the instance on which you want to reset the Administrator password. You will specify this ID in the procedure.
- Optionally, collect the ID of a subnet in the same availability zone as your unreachable instance. The EC2Rescue instance will be created in this subnet. If you don't specify a subnet, then Automation creates a new temporary VPC in your AWS account. Verify that your AWS account has at least one VPC available. By default, you can create five VPCs in a Region. If you already created five VPCs in the Region, the automation fails without making changes to your instance. For more information about Amazon VPC quotas, see [VPC and Subnets](#) in the *Amazon VPC User Guide*.
- Optionally, you can create and specify an AWS Identity and Access Management (IAM) role for Automation. If you don't specify this role, then Automation runs in the context of the user who ran the automation.

## Granting AWSSupport-EC2Rescue permissions to perform actions on your instances

EC2Rescue needs permission to perform a series of actions on your instances during the automation. These actions invoke the AWS Lambda, IAM, and Amazon EC2 services to safely and securely attempt to remediate issues with your instances. If you have Administrator-level permissions in your AWS account and/or VPC, you might be able to run the automation without configuring permissions, as described in this section. If you don't have Administrator-level permissions, then you or an administrator must configure permissions by using one of the following options.

- [Granting permissions by using IAM policies](#)
- [Granting permissions by using an AWS CloudFormation template](#)

### Granting permissions by using IAM policies

You can either attach the following IAM policy to your user, group, or role as an inline policy; or, you can create a new IAM managed policy and attach it to your user, group, or role. For more information about adding an inline policy to your user, group, or role see [Working With Inline Policies](#). For more information about creating a new managed policy, see [Working With Managed Policies](#).

#### Note

If you create a new IAM managed policy, you must also attach the **AmazonSSMAutomationRole** managed policy to it so that your instances can communicate with the Systems Manager API.

### IAM Policy for AWSSupport - ResetAccess

Replace *account ID* with your own information.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Action": [
        "lambda:InvokeFunction",
        "lambda>DeleteFunction",
        "lambda:GetFunction"
      ]
    }
  ]
}
```

```

    ],

    ],
    "Resource": "*",
    "Effect": "Allow"
}
]
}

```

## Granting permissions by using an AWS CloudFormation template

AWS CloudFormation automates the process of creating IAM roles and policies by using a preconfigured template. Use the following procedure to create the required IAM roles and policies for the EC2Rescue Automation by using AWS CloudFormation.

### To create the required IAM roles and policies for EC2Rescue

1. Download [AWSSupport-EC2RescueRole.zip](#) and extract the `AWSSupport-EC2RescueRole.json` file to a directory on your local machine.
2. If your AWS account is in a special partition, edit the template to change the ARN values to those for your partition.

For example, for the China Regions, change all cases of `arn:aws` to `arn:aws-cn`.

3. Sign in to the AWS Management Console and open the AWS CloudFormation console at <https://console.aws.amazon.com/cloudformation>.
4. Choose **Create stack, With new resources (standard)**.
5. On the **Create stack** page, for **Prerequisite - Prepare template**, choose **Template is ready**.

6. For **Specify template**, choose **Upload a template file**.
7. Choose **Choose file**, and then browse to and select the `AWSSupport-EC2RescueRole.json` file from the directory where you extracted it.
8. Choose **Next**.
9. On the **Specify stack details** page, for **Stack name** field, enter a name to identify this stack, and then choose **Next**.
10. (Optional) In the **Tags** area, apply one or more tag key name/value pairs to the stack.

Tags are optional metadata that you assign to a resource. Tags enable you to categorize a resource in different ways, such as by purpose, owner, or environment. For example, you might want to tag a stack to identify the type of tasks it runs, the types of targets or other resources involved, and the environment it runs in.

11. Choose **Next**
12. On the **Review** page, review the stack details, and then scroll down and choose the **I acknowledge that AWS CloudFormation might create IAM resources** option.
13. AWS CloudFormation shows the **CREATE\_IN\_PROGRESS** status for a few minutes. The status changes to **CREATE\_COMPLETE** after the stack has been created. You can also choose the refresh icon to check the status of the create process.
14. In the stack list, choose the option next to the stack you just created, and then choose the **Outputs** tab.
15. Copy the **Value**. This is the ARN of the AssumeRole. You will specify this ARN when you run the Automation.

## Running the Automation

The following procedure describes how to run the `AWSSupport-ResetAccess` runbook by using the AWS Systems Manager console.

### Important

The following automation stops the instance. Stopping the instance can result in lost data on attached instance store volumes (if present). Stopping the instance can also cause the public IP to change, if no Elastic IP is associated. To avoid these configuration changes, use Run Command to reset access. For more information, see [Using EC2Rescue for Windows Server with Systems Manager Run Command](#) in the *Amazon EC2 User Guide*.

## To run the AWSSupport-ResetAccess Automation

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
  2. In the navigation pane, choose **Automation**.
  3. Choose **Execute automation**.
  4. In the **Automation document** section, choose **Owned by Amazon** from the list.
  5. In the runbooks list, choose the button in the card for **AWSSupport-ResetAccess**, and then choose **Next**.
  6. In the **Execute automation document** page, choose **Simple execution**.
  7. In the **Document details** section, verify that **Document version** is set to the highest default version. For example, **\$DEFAULT** or **3 (default)**.
  8. In the **Input parameters** section, specify the following parameters:
    - a. For **InstanceID**, specify the ID of the unreachable instance.
    - b. For **SubnetId**, specify a subnet in an existing VPC in the same availability zone as the instance you specified. By default, Systems Manager creates a new VPC, but you can specify a subnet in an existing VPC if you want.
-  **Note**

If you don't see the option to specify a subnet ID, verify that you are using the latest **Default** version of the runbook.
- c. For **EC2RescueInstanceType**, specify an instance type for the EC2Rescue instance. The default instance type is `t2.medium`.
  - d. For **AssumeRole**, if you created roles for this Automation by using the AWS CloudFormation procedure described earlier in this topic, then specify the AssumeRole ARN that you noted in the AWS CloudFormation console.
9. (Optional) In the **Tags** area, apply one or more tag key name/value pairs to help identify the automation, for example `Key=Purpose, Value=ResetAccess`.
10. Choose **Execute**.
11. To monitor the automation progress, choose the running automation, and then choose the **Steps** tab. When the automation is finished, choose the **Descriptions** tab, and then choose

**View output** to view the results. To view the output of individual steps, choose the **Steps** tab, and then choose **View Outputs** next to a step.

The runbook creates a backup AMI and a password-enabled AMI as part of the automation. All other resources created by the automation are automatically deleted, but these AMIs remain in your account. The AMIs are named using the following conventions:

- Backup AMI: AWSSupport-EC2Rescue: *InstanceID*
- Password-enabled AMI: AWSSupport-EC2Rescue: Password-enabled AMI from *Instance ID*

You can locate these AMIs by searching on the Automation execution ID.

For Linux, the new SSH private key for your instance is saved, encrypted, in Parameter Store. The parameter name is `/ec2rl/openssh/instance ID/key`.

### Passing data to Automation using input transformers

This AWS Systems Manager Automation tutorial shows how to use the input transformer feature of Amazon EventBridge to extract the `instance-id` of an Amazon Elastic Compute Cloud (Amazon EC2) instance from an instance state change event. Automation is a capability of AWS Systems Manager. We use the input transformer to pass that data to the `AWS-CreateImage` runbook target as the `InstanceId` input parameter. The rule is triggered when any instance changes to the stopped state.

For more information about working with input transformers, see [Tutorial: Use Input Transformer to Customize What is Passed to the Event Target](#) in the *Amazon EventBridge User Guide*.

### Before you begin

Verify that you added the required permissions and trust policy for EventBridge to your Systems Manager Automation service role. For more information, see [Overview of Managing Access Permissions to Your EventBridge Resources](#) in the *Amazon EventBridge User Guide*.

### To use input transformers with Automation

1. Open the Amazon EventBridge console at <https://console.aws.amazon.com/events/>.
2. In the navigation pane, choose **Rules**.
3. Choose **Create rule**.
4. Enter a name and description for the rule.

- A rule can't have the same name as another rule in the same Region and on the same event bus.
- For **Event bus**, choose the event bus that you want to associate with this rule. If you want this rule to respond to matching events that come from your own AWS account, select **default**. When an AWS service in your account emits an event, it always goes to your account's default event bus.
  - For **Rule type**, choose **Rule with an event pattern**.
  - Choose **Next**.
  - For **Event source**, choose **AWS events or EventBridge partner events**.
  - In the **Event pattern** section, choose **Event pattern form**.
  - For **Event source**, choose **AWS services**.
  - For **AWS service**, choose **EC2**.
  - For **Event type**, choose **EC2 Instance State-change Notification**.
  - For **Specific state(s)**, choose **stopped**.
  - Choose **Next**.
  - For **Target types**, choose **AWS service**.
  - For **Select a target**, choose **Systems Manager Automation**.
  - For **Document**, choose **AWS-CreateImage**.
  - In the **Configure automation parameter(s)** section, choose **Input Transformer**.
  - For **Input path**, enter `{"instance": "$.detail.instance-id"}`.
  - For **Template**, enter `{"InstanceId": [<instance>]}`.
  - For **Execution role**, choose **Use existing role** and choose your Automation service role.
  - Choose **Next**.
  - (Optional) Enter one or more tags for the rule. For more information, see [Tagging Your Amazon EventBridge Resources](#) in the *Amazon EventBridge User Guide*.
  - Choose **Next**.
  - Review the details of the rule and choose **Create rule**.

## Learn about statuses returned by Systems Manager Automation

AWS Systems Manager Automation reports detailed status information about the various statuses an automation action or step goes through when you run an automation and for the overall

automation. Automation is a capability of AWS Systems Manager. You can monitor automation statuses using the following methods:

- Monitor the **Execution status** in the Systems Manager Automation console.
- Use your preferred command line tools. For the AWS Command Line Interface (AWS CLI), you can use [describe-automation-step-executions](#) or [get-automation-execution](#). For the AWS Tools for Windows PowerShell, you can use [Get-SSMAutomationStepExecution](#) or [Get-SSMAutomationExecution](#).
- Configure Amazon EventBridge to respond to action or automation status changes.

For more information about handling timeouts in an automation, see [Handling timeouts in runbooks](#).

## About automation statuses

Automation reports status details for individual automation actions in addition to the overall automation.

The overall automation status can be different than the status reported by an individual action or step as noted in the following tables.

### Detailed status for actions

| Status     | Details   |
|------------|---|
| Pending    | The step hasn't started running. If your automation uses conditional actions, steps remain in this state after an automation has completed if the condition wasn't met to run the step. Steps also remain in this state if the automation is canceled before the step runs. |
| InProgress | The step is running.  |
| Waiting    | The step is waiting for input.  |
| Success    | The step completed successfully. This is a terminal state.  |

| Status     | Details  |
|------------|--|
| TimedOut   | A step or approval wasn't completed before the specified timeout period. This is a terminal state.   |
| Cancelling | The step is in the process of stopping after being canceled by a requester.  |
| Cancelled  | The step was stopped by a requester before it completed. This is a terminal state.   |
| Failed     | The step didn't complete successfully. This is a terminal state.   |
| Exited     | Only returned by the <code>aws:loop</code> action. The loop didn't fully complete. A step inside the loop moved to an outside step using the <code>nextStep</code> , <code>onCancel</code> , or <code>onFailure</code> properties. |

### Detailed status for an automation

| Status     | Details  |
|------------|--|
| Pending    | The automation hasn't started running.   |
| InProgress | The automation is running.   |
| Waiting    | The automation is waiting for input.   |
| Success    | The automation completed successfully. This is a terminal state.                                   |
| TimedOut   | A step or approval wasn't completed before the specified timeout period. This is a terminal state. |

| Status     | Details  |
|------------|--|
| Cancelling | The automation is in the process of stopping after being canceled by a requester.        |
| Cancelled  | The automation was stopped by a requester before it completed. This is a terminal state. |
| Failed     | The automation didn't complete successfully. This is a terminal state.                   |

## Troubleshooting Systems Manager Automation

Use the following information to help you troubleshoot problems with AWS Systems Manager Automation, a capability of AWS Systems Manager. This topic includes specific tasks to resolve issues based on Automation error messages.

### Topics

- [Common Automation errors](#)
- [Automation execution failed to start](#)
- [Execution started, but status is failed](#)
- [Execution started, but timed out](#)

### Common Automation errors

This section includes information about common Automation errors.

#### VPC not defined 400

By default, when Automation runs either the `AWS-UpdateLinuxAmi` runbook or the `AWS-UpdateWindowsAmi` runbook, the system creates a temporary instance in the default VPC (172.30.0.0/16). If you deleted the default VPC, you will receive the following error:

```
VPC not defined 400
```

To solve this problem, you must specify a value for the `SubnetId` input parameter.

## Automation execution failed to start

An automation can fail with an access denied error or an invalid assume role error if you haven't properly configured AWS Identity and Access Management (IAM) roles, and policies for Automation.

### Access denied

The following examples describe situations when an automation failed to start with an access denied error.

#### Access Denied to Systems Manager API

**Error message:** User: user arn isn't authorized to perform: ssm:StartAutomationExecution on resource: document arn (Service: AWSSimpleSystemsManagement; Status Code: 400; Error Code: AccessDeniedException; Request ID: xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx)

- Possible cause 1: The user attempting to start the automation doesn't have permission to invoke the `StartAutomationExecution` API. To resolve this issue, attach the required IAM policy to the user that was used to start the automation.
- Possible cause 2: The user attempting to start the automation has permission to invoke the `StartAutomationExecution` API but doesn't have permission to invoke the API by using the specific runbook. To resolve this issue, attach the required IAM policy to the user that was used to start the automation.

#### Access denied due to missing PassRole permissions

**Error message:** User: user arn isn't authorized to perform: iam:PassRole on resource: automation assume role arn (Service: AWSSimpleSystemsManagement; Status Code: 400; Error Code: AccessDeniedException; Request ID: xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx)

The user attempting to start the automation doesn't have `PassRole` permission for the assume role. To resolve this issue, attach the `iam:PassRole` policy to the role of the user attempting to start the automation. For more information, see [Task 2: Attach the iam:PassRole policy to your Automation role](#).

## Invalid assume role

When you run an Automation, an assume role is either provided in the runbook or passed as a parameter value for the runbook. Different types of errors can occur if the assume role isn't specified or configured properly.

### Malformed Assume Role

**Error message:** The format of the supplied assume role ARN isn't valid. The assume role is improperly formatted. To resolve this issue, verify that a valid assume role is specified in your runbook or as a runtime parameter when starting the automation.

### Assume role can't be assumed

**Error message:** The defined assume role is unable to be assumed.

(Service: AWSSimpleSystemsManagement; Status Code: 400; Error Code: InvalidAutomationExecutionParametersException; Request ID: xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx)

- Possible cause 1: The assume role doesn't exist. To resolve this issue, create the role. For more information, see [the section called "Setting up Automation"](#). Specific details for creating this role are described in the following topic, [Task 1: Create a service role for Automation](#).
- Possible cause 2: The assume role doesn't have a trust relationship with the Systems Manager service. To resolve this issue, create the trust relationship. For more information, see [I Can't Assume A Role](#) in the *IAM User Guide*.

## Execution started, but status is failed

### Action-specific failures

Runbooks contain steps and steps run in order. Each step invokes one or more AWS service APIs. The APIs determine the inputs, behavior, and outputs of the step. There are multiple places where an error can cause a step to fail. Failure messages indicate when and where an error occurred.

To see a failure message in the Amazon Elastic Compute Cloud (Amazon EC2) console, choose the **View Outputs** link of the failed step. To see a failure message from the AWS CLI, call `get-automation-execution` and look for the `FailureMessage` attribute in a failed `StepExecution`.

In the following examples, a step associated with the `aws:runInstance` action failed. Each example explores a different type of error.

### Missing Image

**Error message:** Automation Step Execution fails when it's launching the instance(s). Get Exception from RunInstances API of ec2 Service. Exception Message from RunInstances API: [The image id '[ami id]' doesn't exist (Service: AmazonEC2; Status Code: 400; Error Code: InvalidAMIID.NotFound; Request ID: xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx)]. Please refer to Automation Service Troubleshooting Guide for more diagnosis details.

The `aws:runInstances` action received input for an `ImageId` that doesn't exist. To resolve this problem, update the runbook or parameter values with the correct AMI ID.

### Assume role policy lacks sufficient permissions

**Error message:** Automation Step Execution fails when it's launching the instance(s). Get Exception from RunInstances API of ec2 Service. Exception Message from RunInstances API: [You aren't authorized to perform this operation. Encoded authorization failure message: xxxxxxxx (Service: AmazonEC2; Status Code: 403; Error Code: UnauthorizedOperation; Request ID: xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx)]. Please refer to Automation Service Troubleshooting Guide for more diagnosis details.

The assume role doesn't have sufficient permission to invoke the RunInstances API on EC2 instances. To resolve this problem, attach an IAM policy to the assume role that has permission to invoke the RunInstances API. For more information, see the [Create the service roles for Automation using the console](#).

### Unexpected State

**Error message:** Step fails when it's verifying launched instance(s) are ready to be used. Instance `i-xxxxxxx` entered unexpected state: shutting-down. Please refer to Automation Service Troubleshooting Guide for more diagnosis details.

- Possible cause 1: There is a problem with the instance or the Amazon EC2 service. To resolve this problem, login to the instance or review the instance system log to understand why the instance started shutting down.

- Possible cause 2: The user data script specified for the `aws:runInstances` action has a problem or incorrect syntax. Verify the syntax of the user data script. Also, verify that the user data scripts doesn't shut down the instance, or invoke other scripts that shut down the instance.

## Action-Specific Failures Reference

When a step fails, the failure message might indicate which service was being invoked when the failure occurred. The following table lists the services invoked by each action. The table also provides links to information about each service.

| Action                               | AWS services invoked by this action | For information about this service              | Troubleshooting content                                     |
|--------------------------------------|-------------------------------------|---|---|
| <code>aws:runInstances</code>        | Amazon EC2                          | <a href="#">Amazon EC2 User Guide</a>           | <a href="#">Troubleshooting EC2 Instances</a>               |
| <code>aws:changeInstanceState</code> | Amazon EC2                          | <a href="#">Amazon EC2 User Guide</a>           | <a href="#">Troubleshooting EC2 instances</a>               |

### Automation service internal error

**Error message:** Internal Server Error. Please refer to Automation Service Troubleshooting Guide for more diagnosis details.

A problem with the Automation service is preventing the specified runbook from running correctly. To resolve this issue, contact AWS Support. Provide the execution ID and customer ID, if available.

### Execution started, but timed out

**Error message:** Step timed out while step is verifying launched instance(s) are ready to be used. Please refer to Automation Service Troubleshooting Guide for more diagnosis details.

A step in the `aws:runInstances` action timed out. This can happen if the step action takes longer to run than the value specified for `timeoutSeconds` in the step. To resolve this issue, specify a longer value for the `timeoutSeconds` parameter in the `aws:runInstances` action. If that doesn't solve the problem, investigate why the step takes longer to run than expected.

## AWS Systems Manager Change Calendar

Change Calendar, a capability of AWS Systems Manager, allows you to set up date and time ranges when actions you specify (for example, in [Systems Manager Automation](#) runbooks) might or might not be performed in your AWS account. In Change Calendar, these ranges are called *events*. When you create a Change Calendar entry, you're creating a [Systems Manager document](#) of the type `ChangeCalendar`. In Change Calendar, the document stores [iCalendar 2.0](#) data in plaintext format. Events that you add to the Change Calendar entry become part of the document. To get

started with Change Calendar, open the [Systems Manager console](#). In the navigation pane, choose **Change Calendar**.

You can create a calendar and its events in the Systems Manager console. You can also import an iCalendar (.ics) file that you have exported from a supported third-party calendar provider to add its events to your calendar. Supported providers include Google Calendar, Microsoft Outlook, and iCloud Calendar.

A Change Calendar entry can be one of two types:

#### **DEFAULT\_OPEN**, or Open by default

All actions can run by default, except during calendar events. During events, the state of a DEFAULT\_OPEN calendar is CLOSED and events are blocked from running.

#### **DEFAULT\_CLOSED**, or Closed by default

All actions are blocked by default, except during calendar events. During events, the state of a DEFAULT\_CLOSED calendar is OPEN and actions are permitted to run.

You can choose to have all scheduled Automation workflows, maintenance windows, and State Manager associations added automatically to a calendar. You can also remove any of those individual types from the calendar display.

## **Who should use Change Calendar?**

- AWS customers who perform the following action types:
  - Create or run Automation runbooks.
  - Create change requests in Change Manager.
  - Run maintenance windows.
  - Create associations in State Manager.

Automation, Change Manager, Maintenance Windows, and State Manager are all capabilities of AWS Systems Manager. By integrating these capabilities with Change Calendar, you can allow or block these action types depending on the current state of the change calendar you associate with each one.

- Administrators who are responsible for keeping the configurations of Systems Manager managed nodes consistent, stable, and functional.

## Benefits of Change Calendar

The following are some benefits of Change Calendar.

- **Review changes before they're applied**

A Change Calendar entry can help ensure that potentially destructive changes to your environment are reviewed before they're applied.

- **Apply changes only during appropriate times**

Change Calendar entries help keep your environment stable during event times. For example, you can create a Change Calendar entry to block changes when you expect high demand on your resources, such as during a conference or public marketing promotion. A calendar entry can also block changes when you expect limited administrator support, such as during vacations or holidays. You can use a calendar entry to allow changes except for certain times of the day or week when there is limited administrator support to troubleshoot failed actions or deployments.

- **Get the current or upcoming state of the calendar**

You can run the Systems Manager `GetCalendarState` API operation to show you the current state of the calendar, the state at a specified time, or the next time that the calendar state is scheduled to change.

- **EventBridge support**

This Systems Manager capability is supported as an *event* type in Amazon EventBridge rules. For information, see [Monitoring Systems Manager events with Amazon EventBridge](#) and [Reference: Amazon EventBridge event patterns and types for Systems Manager](#).

### Topics

- [Setting up Change Calendar](#)
- [Working with Change Calendar](#)
- [Adding Change Calendar dependencies to Automation runbooks](#)
- [Troubleshooting Change Calendar](#)

## Setting up Change Calendar

Complete the following before using Change Calendar, a capability of AWS Systems Manager.

## Install latest command line tools

Install the latest command line tools to get state information about calendars.

| Requirement              | Description  |
|--------------------------|--|
| AWS CLI                  | <p>(Optional) To use the AWS Command Line Interface (AWS CLI) to get state information about calendars, install the newest release of the AWS CLI on your local computer.</p> <p>For more information about how to install or upgrade the CLI, see <a href="#">Installing, updating, and uninstalling the AWS CLI</a> in the <i>AWS Command Line Interface User Guide</i>.</p> |
| AWS Tools for PowerShell | <p>(Optional) To use the Tools for PowerShell to get state information about calendars, install the newest release of Tools for PowerShell on your local computer.</p> <p>For more information about how to install or upgrade the Tools for PowerShell, see <a href="#">Installing the AWS Tools for PowerShell</a> in the <i>AWS Tools for PowerShell User Guide</i>.</p>    |

## Set up permissions

If your user, group, or role is assigned administrator permissions, then you have full access to Change Calendar. If you don't have administrator permissions, then an administrator must give you permission by either assigning the AmazonSSMFullAccess managed policy, or assigning a policy that provides the necessary permissions to your user, group, or role.

The following permissions are required to work with Change Calendar.

## Change Calendar entries

To create, update, or delete a Change Calendar entry, including adding and removing events from the entry, a policy attached to your user, group, or role must allow the following actions:

- `ssm:CreateDocument`
- `ssm>DeleteDocument`
- `ssm:DescribeDocument`
- `ssm:DescribeDocumentPermission`
- `ssm:GetCalendar`
- `ssm:ListDocuments`
- `ssm:ModifyDocumentPermission`
- `ssm:PutCalendar`
- `ssm:UpdateDocument`
- `ssm:UpdateDocumentDefaultVersion`

### Calendar state

To get information about the current or upcoming state of the calendar, a policy attached to your user, group, or role must allow the following action:

- `ssm:GetCalendarState`

### Operational events

To view operational events, such as maintenance windows, associations, and planned automations, the policy attached to your user, group, or role must allow the following actions:

- `ssm:DescribeMaintenanceWindows`
- `ssm:DescribeMaintenanceWindowExecution`
- `ssm:DescribeAutomationExecutions`
- `ssm:ListAssociations`

#### Note

Change Calendar entries that are owned by (that is, created by) accounts other than yours are read-only, even if they're shared with your account. Maintenance windows, State Manager associations, and automations aren't shared.

## Working with Change Calendar

You can use the AWS Systems Manager console to add, manage, or delete entries in Change Calendar, a capability of AWS Systems Manager. You can also import events from supported third-party calendar providers by importing an iCalendar (.ics) file that you exported from the source calendar. And, you can use the `GetCalendarState` API operation or the `get-calendar-state` AWS Command Line Interface (AWS CLI) command to get information about the state of Change Calendar at a specific time.

### Topics

- [Creating a change calendar](#)
- [Creating and managing events in Change Calendar](#)
- [Importing and managing events from third-party calendars](#)
- [Updating a change calendar](#)
- [Sharing a change calendar](#)
- [Deleting a change calendar](#)
- [Getting the state of a change calendar](#)

### Creating a change calendar

When you create an entry in Change Calendar, a capability of AWS Systems Manager, you're creating a Systems Manager document (SSM document) that uses the `text` format.

#### To create a change calendar

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Change Calendar**.
3. Choose **Create calendar**.

-or-

If the **Change Calendar** home page opens first, choose **Create change calendar**.

4. On the **Create calendar** page, in **Calendar details**, enter a name for your calendar entry. Calendar entry names can contain letters, numbers, periods, dashes, and underscores. The name should be specific enough to identify the purpose of the calendar entry at a glance. An

example is **support-off-hours**. You can't update this name after you create the calendar entry.

5. (Optional) For **Description**, enter a description for your calendar entry.
6. (Optional) In the **Import calendar** area, choose **Choose file** to select an iCalendar (.ics) file that you have exported from a third-party calendar provider. Importing the file will add its events to your calendar.

Supported providers include Google Calendar, Microsoft Outlook, and iCloud Calendar.

For more information, see [Importing events from third-party calendar providers](#).

7. In **Calendar type**, choose one of the following.
  - **Open by default** - The calendar is open (Automation actions can run until an event starts), then closed for the duration of an associated event.
  - **Closed by default** - The calendar is closed (Automation actions can't run until an event starts) but open for the duration of an associated event.
8. (Optional) In **Change management events**, select **Add change management events to the calendar**. This selection displays all scheduled maintenance windows, State Manager associations, Automation workflows, and Change Manager change requests in your monthly calendar display.

 **Tip**

If later you want to permanently remove these events types from the calendar display, edit the calendar, clear this check box, and then choose **Save**.

9. Choose **Create calendar**.

After the calendar entry is created, Systems Manager displays your calendar entry in the **Change Calendar** list. The columns show the calendar version and the calendar owner's AWS account number. Your calendar entry can't prevent or allow any actions until you have created or imported at least one event. For information about creating an event, see [Creating a Change Calendar event](#). For information about importing events, see [Importing events from third-party calendar providers](#).

## Creating and managing events in Change Calendar

After you create a calendar in AWS Systems Manager Change Calendar, you can create, update, and delete events that are included in your open or closed calendar. Change Calendar is a capability of AWS Systems Manager.

### Tip

As an alternative to creating events directly in the Systems Manager console, you can import an iCalendar (.ics) file from a supported third-party calendar application. For information, see [Importing and managing events from third-party calendars](#).

### Topics

- [Creating a Change Calendar event](#)
- [Updating a Change Calendar event](#)
- [Deleting a Change Calendar event](#)

### Creating a Change Calendar event

When you add an event to an entry in Change Calendar, a capability in AWS Systems Manager, you're specifying a period of time during which the default action of the calendar entry is suspended. For example, if the calendar entry type is closed by default, the calendar is open to changes during events. (Alternatively, you can create an advisory event, which serves an informational role on the calendar only.)

Currently, you can only create a Change Calendar event by using the console. Events are added to the Change Calendar document that you create when you create a Change Calendar entry.

### To create a Change Calendar event

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Change Calendar**.
3. In the list of calendars, choose the name of the calendar entry to which you want to add an event.
4. On the calendar entry's details page, choose **Create event**.

5. On the **Create scheduled event** page, in **Event details**, enter a display name for your event. Event names can contain letters, numbers, periods, dashes, and underscores. The name should be specific enough to identify the purpose of the event. An example is **nighttime-hours**.
6. For **Description**, enter a description for your event. For example, **The support team isn't available during these hours**.
7. (Optional) If you want this event to serve as a visual notification or reminder only, select the **Advisory** check box. Advisory events play no functional role on your calendar. They serve informational purposes only for those who view your calendar.
8. For **Event start date**, enter or choose a day in the format MM/DD/YYYY to start the event, and enter a time on the specified day in the format hh:mm:ss (hours, minutes, and seconds) to start the event.
9. For **Event end date**, enter or choose a day in the format MM/DD/YYYY to end the event, and enter a time on the specified day in the format hh:mm:ss (hours, minutes, and seconds) to end the event.
10. For **Schedule time zone**, choose a time zone that applies to the start and end times of the event. You can enter part of a city name or time zone difference from Greenwich Mean Time (GMT) to find a time zone faster. The default is Coordinated Universal Time (UTC).
11. (Optional) To create an event that recurs daily, weekly, or monthly, turn on **Recurrence**, and then specify the frequency and optional end date for the recurrence.
12. Choose **Create scheduled event**. The new event is added to your calendar entry, and is displayed on the **Events** tab of the calendar entry's details page.

## Updating a Change Calendar event

Use the following procedure to update a Change Calendar event in the AWS Systems Manager console. Change Calendar is a capability of AWS Systems Manager.

### To update a Change Calendar event

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Change Calendar**.
3. In the list of calendars, choose the name of the calendar entry for which you want to edit an event.
4. On the calendar entry's details page, choose **Events**.

5. In the calendar page, choose the event that you want to edit.

** Tip**

Use the buttons on the upper left to move back or forward one year, or back or forward one month. Change the time zone, if required, by choosing the correct time zone from the list on the upper right.

6. In **Event details**, choose **Edit**.

To change the event name and description, add to or replace the current text values.

7. To change the **Event start date** value, choose the current start date, and then choose a new date from the calendar. To change the start time, choose the current start time, and then choose a new time from the list.
8. To change the **Event end date** value, choose the current date, and then choose a new end date from the calendar. To change the end time, choose the current end time, and then choose a new time from the list.
9. To change the **Schedule time zone** value, choose a time zone to apply to the start and end times of the event. You can enter part of a city name or time zone difference from Greenwich Mean Time (GMT) to find a time zone faster. The default is Coordinated Universal Time (UTC).
10. (Optional) If you want this event to serve as a visual notification or reminder only, select the **Advisory** check box. Advisory events play no functional role on your calendar. They serve informational purposes only for those who view your calendar.
11. Choose **Save**. Your changes are displayed on the **Events** tab of the calendar entry's details page. Choose the event that you updated to view your changes.

## Deleting a Change Calendar event

You can delete one event at a time in Change Calendar, a capability in AWS Systems Manager, by using the AWS Management Console.

** Tip**

If you selected **Add change management events to the calendar** when you created the calendar, you can do the following:

- To *temporarily* hide a change management event type from the calendar display, choose the **X** for the type at the top of the monthly preview.
- To *permanently* remove these types from the calendar display, edit the calendar, clear the **Add change management events to the calendar** check box, and then choose **Save**. Removing the types from the calendar display doesn't delete them from your account.

## To delete a Change Calendar event

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Change Calendar**.
3. In the list of calendars, choose the name of the calendar entry from which you want to delete an event.
4. On the calendar entry's details page, choose **Events**.
5. In the calendar page, choose the event that you want to delete.

### Tip

Use the buttons on the upper left to move the calendar back or forward one year, or back or forward one month. Change the time zone, if required, by choosing the correct time zone from the list on the upper right.

6. On the **Event details** page, choose **Delete**. When you're prompted to confirm that you want to delete the event, choose **Confirm**.

## Importing and managing events from third-party calendars

As an alternative to creating events directly in the AWS Systems Manager console, you can import an iCalendar (.ics) file from a supported third-party calendar application. Your calendar can include both imported events and events that you create in Change Calendar, which is a capability of AWS Systems Manager.

### Before you begin

Before you attempt to import a calendar file, review the following requirements and constraints:

## Calendar file format

Only valid iCalendar files (.ics) are supported.

## Supported calendar providers

Only .ics files exported from the following third-party calendar providers are supported:

- Google Calendar ([Export instructions](#))
- Microsoft Outlook ([Export instructions](#))
- iCloud Calendar ([Export instructions](#))

## File size

You can import any number of valid .ics files. However, the total size of all imported files for each calendar can't exceed 64KB.

### Tip

To minimize the size of the .ics file, ensure that you are exporting only basic details about your calendar entries. If necessary, reduce the length of the time period that you are exporting.

## Time zone

In addition to a calendar name, a calendar provider, and at least one event, your exported .ics file should also indicate the time zone for the calendar. If it does not, or there is a problem identifying the time zone, you will be prompted to specify one after you import the file.

## Recurring event limitation

Your exported .ics file can include recurring events. However, if one or more occurrences of a recurring event had been deleted in the source calendar, the import fails.

## Topics

- [Importing events from third-party calendar providers](#)
- [Updating all events from a third-party calendar provider](#)
- [Deleting all events imported from a third-party calendar](#)

## Importing events from third-party calendar providers

Use the following procedure to import an iCalendar (.ics) file from a supported third-party calendar application. The events contained in the file are incorporated into the rules for your open or closed calendar. You can import a file into a new calendar you are creating with Change Calendar (a capability of AWS Systems Manager) or into an existing calendar.

After you import the .ics file, you can remove individual events from it using the Change Calendar interface. For information, see [Deleting a Change Calendar event](#). You can also delete all events from the source calendar by deleting the .ics file. For information, see [Deleting all events imported from a third-party calendar](#).

### To import events from third-party calendar providers

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Change Calendar**.
3. To start with a new calendar, choose **Create calendar**. In the **Import calendar** area, choose **Choose file**. For information about other steps to create a new calendar, see [Creating a change calendar](#).

-or-

To import third-party events into an existing calendar, choose the name of an existing calendar to open it.

4. Choose **Actions, Edit**, and then in the **Import calendar** area, choose **Choose file**.
5. Navigate to and select the exported .ics file on your local computer.
6. If prompted, for **Select a time zone**, select which time zone applies to the calendar.
7. Choose **Save**.

### Updating all events from a third-party calendar provider

If several events are added to or removed from your source calendar after you have imported its iCalendar .ics file, you can reflect those changes in Change Calendar. First, re-export the source calendar, and then import the new file into Change Calendar, which is a capability of AWS Systems Manager. Events in your change calendar will be updated to reflect the contents of the newer file.

## To update all events from a third-party calendar provider

1. In your third-party calendar, add or remove events as you want them to be reflected in Change Calendar, and then re-export the calendar to a new `.ics` file.
2. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
3. In the navigation pane, choose **Change Calendar**.
4. From the list of calendars, choose the calendar name from the list.
5. Choose **Choose file**, and then navigate to and select the replacement `.ics` file.
6. In response to the notification about overwriting the existing file, choose **Confirm**.

## Deleting all events imported from a third-party calendar

If you no longer want any of the events that you imported from a third-party provider included in your calendar, you can delete the imported iCalendar `.ics` file.

## To delete all events imported from a third-party calendar

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Change Calendar**.
3. From the list of calendars, choose the calendar name from the list.
4. In the **Import calendar** area, under **My imported calendars**, locate the name of the imported calendar, and then choose the **X** in its card.
5. Choose **Save**.

## Updating a change calendar

You can update the description of a change calendar, but not its name. Although you can change the default state of a calendar, be aware that this reverses the behavior of change actions during events that are associated with the calendar. For example, if you change the state of a calendar from **Open by default** to **Closed by default**, unwanted changes might be made during event periods when the users who created the associated events aren't expecting changes.

When you update a change calendar, you're editing the Change Calendar document that you created when you created the entry. Change Calendar is a capability of AWS Systems Manager.

## To update a change calendar

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Change Calendar**.
3. In the list of calendars, choose the name of the calendar that you want to update.
4. On the calendar's details page, choose **Actions, Edit**.
5. In **Description**, you can change the description text. You can't edit the name of a change calendar.
6. To change the calendar state, in **Calendar type**, choose a different value. Be aware that this reverses the behavior of change actions during events that are associated with the calendar. Before you change the calendar type, you should verify with other Change Calendar users that changing the calendar type doesn't allow unwanted changes during events that they have created.
  - **Open by default** – The calendar is open (Automation actions can run until an event starts) then closed for the duration of an associated event.
  - **Closed by default** – The calendar is closed (Automation actions can't run until an event starts) but open for the duration of an associated event.
7. Choose **Save**.

Your calendar can't prevent or allow any actions until you add at least one event. For information about how to add an event, see [Creating a Change Calendar event](#).

## Sharing a change calendar

You can share a calendar in Change Calendar, a capability of AWS Systems Manager, with other AWS accounts by using the AWS Systems Manager console. When you share a calendar, the calendar is read-only to users in the shared account. Maintenance windows, State Manager associations, and automations aren't shared.

## To share a change calendar

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Change Calendar**.

3. In the list of calendars, choose the name of the calendar that you want to share.
4. On the calendar's details page, choose the **Sharing** tab.
5. Choose **Actions, Share**.
6. In **Share calendar**, for **Account ID**, enter the ID number of a valid AWS account, and then choose **Share**.

Users of the shared account can read the change calendar, but they can't make changes.

## Deleting a change calendar

You can delete a calendar in Change Calendar, a capability of AWS Systems Manager, by using either the Systems Manager console or the AWS Command Line Interface (AWS CLI). Deleting a change calendar deletes all associated events.

### To delete a change calendar

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Change Calendar**.
3. In the list of calendars, choose the name of the calendar that you want to delete.
4. On the calendar's details page, choose **Actions, Delete**. When you're prompted to confirm that you want to delete the calendar, choose **Delete**.

## Getting the state of a change calendar

You can get the overall state of a calendar or the state of a calendar at a specific time in Change Calendar, a capability in AWS Systems Manager. You can also show the next time that the calendar state changes from OPEN to CLOSED, or the reverse.

You can do this task only by using the `GetCalendarState` API operation. The procedure in this section uses the AWS Command Line Interface (AWS CLI).

### To get the state of a change calendar

- Run the following command to show the state of one or more calendars at a specific time. The `--calendar-names` parameter is required, but `--at-time` is optional. Replace each *example resource placeholder* with your own information.

## Linux & macOS

```
aws ssm get-calendar-state \  
  --calendar-names "Calendar_name_or_document_ARN_1"  
  "Calendar_name_or_document_ARN_2" \  
  --at-time "ISO_8601_time_format"
```

The following is an example.

```
aws ssm get-calendar-state \  
  --calendar-names "arn:aws:ssm:us-east-2:123456789012:document/  
MyChangeCalendarDocument" "arn:aws:ssm:us-east-2:123456789012:document/  
SupportOffHours" \  
  --at-time "2020-07-30T11:05:14-0700"
```

## Windows

```
aws ssm get-calendar-state ^  
  --calendar-names "Calendar_name_or_document_ARN_1"  
  "Calendar_name_or_document_ARN_2" ^  
  --at-time "ISO_8601_time_format"
```

The following is an example.

```
aws ssm get-calendar-state ^  
  --calendar-names "arn:aws:ssm:us-east-2:123456789012:document/  
MyChangeCalendarDocument" "arn:aws:ssm:us-east-2:123456789012:document/  
SupportOffHours" ^  
  --at-time "2020-07-30T11:05:14-0700"
```

The command returns information like the following.

```
{  
  "State": "OPEN",  
  "AtTime": "2020-07-30T16:18:18Z",  
  "NextTransitionTime": "2020-07-31T00:00:00Z"  
}
```

The results show the state of the calendar (whether the calendar is of type `DEFAULT_OPEN` or `DEFAULT_CLOSED`) for the specified calendar entries that are owned by or shared with your account, at the time specified as the value of `--at-time`, and the time of the next transition. If you don't add the `--at-time` parameter, the current time is used.

**Note**

If you specify more than one calendar in a request, the command returns the status of `OPEN` only if all calendars in the request are open. If one or more calendars in the request are closed, the status returned is `CLOSED`.

## Adding Change Calendar dependencies to Automation runbooks

To make Automation actions adhere to Change Calendar, a capability of AWS Systems Manager, add a step in an Automation runbook that uses the [aws:assertAwsResourceProperty](#) action. Configure the action to run `GetCalendarState` to verify that a specified calendar entry is in the state that you want (`OPEN` or `CLOSED`). The Automation runbook is only allowed to continue to the next step if the calendar state is `OPEN`. The following is a YAML-based sample excerpt of an Automation runbook that can't advance to the next step, `LaunchInstance`, unless the calendar state matches `OPEN`, the state specified in `DesiredValues`.

The following is an example.

```
mainSteps:
  - name: MyCheckCalendarStateStep
    action: 'aws:assertAwsResourceProperty'
    inputs:
      Service: ssm
      Api: GetCalendarState
      CalendarNames: ["arn:aws:ssm:us-east-2:123456789012:document/SaleDays"]
      PropertySelector: '$.State'
      DesiredValues:
        - OPEN
    description: "Use GetCalendarState to determine whether a calendar is open or
closed."
    nextStep: LaunchInstance
  - name: LaunchInstance
    action: 'aws:executeScript'
```

```
inputs:
  Runtime: python3.8
...
```

## Troubleshooting Change Calendar

Use the following information to help you troubleshoot problems with Change Calendar, a capability of AWS Systems Manager.

### Topics

- ['Calendar import failed' error](#)

### 'Calendar import failed' error

**Problem:** When importing an iCalendar (.ics) file, the system reports that the calendar import failed.

- **Solution 1** – Ensure that you are importing a file that was exported from a supported third-party calendar provider, which include the following:
  - Google Calendar ([Export instructions](#))
  - Microsoft Outlook ([Export instructions](#))
  - iCloud Calendar ([Export instructions](#))
- **Solution 2** – If your source calendar contains any recurring events, ensure that no individual occurrences of the event have been canceled or deleted. Currently, Change Calendar doesn't support importing recurring events with individual cancellations. To resolve the issue, remove the recurring event from the source calendar, re-export the calendar and re-import it into Change Calendar, and then add the recurring event using the Change Calendar interface. For information, see [Creating a Change Calendar event](#).
- **Solution 3** – Ensure that your source calendar contains at least one event. Uploads of .ics files that don't contain events don't succeed.
- **Solution 4** – If the system reports that the import failed because the .ics is too large, ensure that you are exporting only basic details about your calendar entries. If necessary, reduce the length of the time period that you export.
- **Solution 5** – If Change Calendar is unable to determine the time zone of your exported calendar when you attempt to import it from the **Events** tab, you might receive this message: "Calendar import failed. Change Calendar couldn't locate a valid time zone. You can import the calendar

from the Edit menu." In this case, choose **Actions, Edit**, and then try importing the file from the **Edit calendar** page.

- **Solution 6** – Don't edit the `.ics` file before import. Attempting to modify the contents of the file can corrupt the calendar data. If you have modified the file before attempting the import, export the calendar from the source calendar again, and then re-attempt the upload.

## AWS Systems Manager Maintenance Windows

Maintenance Windows, a capability of AWS Systems Manager, helps you define a schedule for when to perform potentially disruptive actions on your nodes such as patching an operating system, updating drivers, or installing software or patches.

### Note

State Manager and Maintenance Windows can perform some similar types of updates on your managed nodes. Which one you choose depends on whether you need to automate system compliance or perform high-priority, time-sensitive tasks during periods you specify.

For more information, see [Choosing between State Manager and Maintenance Windows](#).

With Maintenance Windows, you can schedule actions on numerous other AWS resource types, such as Amazon Simple Storage Service (Amazon S3) buckets, Amazon Simple Queue Service (Amazon SQS) queues, AWS Key Management Service (AWS KMS) keys, and many more.

For a full list of supported resource types that you can include in a maintenance window target, see [Resources you can use with AWS Resource Groups and Tag Editor](#) in the *AWS Resource Groups User Guide*. To get started with Maintenance Windows, open the [Systems Manager console](#). In the navigation pane, choose **Maintenance Windows**.

Each maintenance window has a schedule, a maximum duration, a set of registered targets (the managed nodes or other AWS resources that are acted upon), and a set of registered tasks. You can add tags to your maintenance windows when you create or update them. (Tags are keys that help identify and sort your resources within your organization.) You can also specify dates that a maintenance window shouldn't run before or after, and you can specify the international time zone on which to base the maintenance window schedule.

For an explanation of how the various schedule-related options for maintenance windows relate to one another, see [Maintenance window scheduling and active period options](#).

For more information about working with the `--schedule` option, see [Reference: Cron and rate expressions for Systems Manager](#).

## Supported task types

With maintenance windows, you can run four types of tasks:

- Commands in Run Command, a capability of Systems Manager

For more information about Run Command, see [AWS Systems Manager Run Command](#).

- Workflows in Automation, a capability of Systems Manager

For more information about Automation workflows, see [AWS Systems Manager Automation](#).

- Functions in AWS Lambda

For more information about Lambda functions, see [Getting started with Lambda](#) in the *AWS Lambda Developer Guide*.

- Tasks in AWS Step Functions

### Note

Maintenance window tasks support Step Functions Standard state machine workflows only. They don't support Express state machine workflows. For information about state machine workflow types, see [Standard vs. Express Workflows](#) in the *AWS Step Functions Developer Guide*.

For more information about Step Functions, see the [AWS Step Functions Developer Guide](#).

This means you can use maintenance windows to perform tasks such as the following on your selected targets.

- Install or update applications.
- Apply patches.
- Install or update SSM Agent.

- Run PowerShell commands and Linux shell scripts by using a Systems Manager Run Command task.
- Build Amazon Machine Images (AMIs), boot-strap software, and configure nodes by using a Systems Manager Automation task.
- Run AWS Lambda functions that invokes additional actions, such as scanning your nodes for patch updates.
- Run AWS Step Functions state machines to perform tasks such as removing a node from an Elastic Load Balancing environment, patching the node, and then adding the node back to the Elastic Load Balancing environment.
- Target nodes that are offline by specifying an AWS resource group as the target.

### Note

One or more targets must be specified for maintenance window Run Command-type tasks. Depending on the task, targets are optional for other maintenance window task types (Automation, AWS Lambda, and AWS Step Functions). For more information about running tasks that don't specify targets, see [Registering maintenance window tasks without targets](#).

## EventBridge support

This Systems Manager capability is supported as an *event* type in Amazon EventBridge rules. For information, see [Monitoring Systems Manager events with Amazon EventBridge](#) and [Reference: Amazon EventBridge event patterns and types for Systems Manager](#).

## Contents

- [Setting up Maintenance Windows](#)
- [Create and manage maintenance windows using the console](#)
- [Tutorials](#)
- [Using pseudo parameters when registering maintenance window tasks](#)
- [Maintenance window scheduling and active period options](#)
- [Registering maintenance window tasks without targets](#)
- [Troubleshooting maintenance windows](#)

## Setting up Maintenance Windows

Before users in your AWS account can create and schedule maintenance window tasks using Maintenance Windows, a capability of AWS Systems Manager, they must be granted the necessary permissions. In addition, you must create an IAM service role for maintenance windows and the IAM policy to attach to it.

### Before you begin

In addition to the permissions you configure in this section, the IAM Entities (users, roles, or groups that will work with maintenance windows should already have general maintenance window permissions. You can grant these permissions by assigning the IAM policy `AmazonSSMFullAccess` to the Entities, or assigning a custom IAM policy that provides a smaller set of access permissions for Systems Manager that covers maintenance window tasks.

### Topics

- [Control access to maintenance windows using the console](#)
- [Control access to maintenance windows using the AWS CLI](#)

### Control access to maintenance windows using the console

The following procedures describe how to use the AWS Systems Manager console to create the required permissions and roles for maintenance windows.

### Topics

- [Task 1: Create a custom policy for your maintenance window service role using the console](#)
- [Task 2: Create a custom service role for maintenance windows using the console](#)
- [Task 3: Grant permissions to specified users to register maintenance window tasks using the console](#)
- [Task 4: Prevent specified users from registering maintenance window tasks using the console](#)

### Task 1: Create a custom policy for your maintenance window service role using the console

Maintenance window tasks require an IAM role to provide the permissions required to run on the target resources. The permissions are provided through an IAM policy attached to the role. The types of tasks you run and your other operational requirements determine the contents of this policy. We provide a base policy you can adapt to your needs. Depending on the tasks and types

of tasks your maintenance windows run, you might not need all the permissions in this policy, and you might need to include additional permissions. You attach this policy to the role that you create later in [Task 2: Create a custom service role for maintenance windows using the console](#).

### To create a custom policy using the console

1. Open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **Policies**, and then choose **Create policy**.
3. In the **Policy editor** area, choose **JSON**.
4. Replace the default contents with the following:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ssm:SendCommand",
        "ssm:CancelCommand",
        "ssm:ListCommands",
        "ssm:ListCommandInvocations",
        "ssm:GetCommandInvocation",
        "ssm:GetAutomationExecution",
        "ssm:StartAutomationExecution",
        "ssm:ListTagsForResource",
        "ssm:GetParameters"
      ],
      "Resource": "*"
    },
    {
      "Effect": "Allow",
      "Action": [
        "states:DescribeExecution",
        "states:StartExecution"
      ],
      "Resource": [
        "arn:aws:states:*:*:execution:*:*",
        "arn:aws:states:*:*:stateMachine:*"
      ]
    }
  ]
}
```

```

    "Effect": "Allow",
    "Action": [
        "lambda:InvokeFunction"
    ],
    "Resource": [
        "arn:aws:lambda:*:*:function:*"
    ]
},
{
    "Effect": "Allow",
    "Action": [
        "resource-groups:ListGroup",
        "resource-groups:ListGroupResources"
    ],
    "Resource": [
        "*"
    ]
},
{
    "Effect": "Allow",
    "Action": [
        "tag:GetResources"
    ],
    "Resource": [
        "*"
    ]
},
{
    "Effect": "Allow",
    "Action": "iam:PassRole",
    "Resource": "*",
    "Condition": {
        "StringEquals": {
            "iam:PassedToService": [
                "ssm.amazonaws.com"
            ]
        }
    }
}
]
}

```

5. Modify the JSON content as needed for the maintenance tasks that you run in your account. The changes you make are specific to your planned operations.

For example:

- You can provide Amazon Resource Names (ARNs) for specific functions and state machines instead of using wildcard (\*) qualifiers.
- If you don't plan to run AWS Step Functions tasks, you can remove the `states` permissions and (ARNs).
- If you don't plan to run AWS Lambda tasks, you can remove the `lambda` permissions and ARNs.
- If you don't plan to run Automation tasks, you can remove the `ssm:GetAutomationExecution` and `ssm:StartAutomationExecution` permissions.
- Add additional permissions that might be needed for the tasks to run. For example, some Automation actions work with AWS CloudFormation stacks. Therefore, the permissions `cloudformation:CreateStack`, `cloudformation:DescribeStacks`, and `cloudformation>DeleteStack` are required.

For another example, the Automation runbook `AWS-CopySnapshot` requires permissions to create an Amazon Elastic Block Store (Amazon EBS) snapshot. Therefore, the service role needs the permission `ec2:CreateSnapshot`.

For information about the role permissions needed by Automation runbooks, see the runbook descriptions in the [AWS Systems Manager Automation runbook reference](#).

6. After completing the policy revisions, choose **Next**.
7. For **Policy name**, enter a name that identifies this as the policy attached to the service role you create. For example: **my-maintenance-window-role-policy**.
8. (Optional) In the **Add tags** area, add one or more tag-key value pairs to organize, track, or control access for this policy.
9. Choose **Create policy**.

Make a note of the name you specified for the policy. You refer to it in the next procedure, [Task 2: Create a custom service role for maintenance windows using the console](#).

## Task 2: Create a custom service role for maintenance windows using the console

The policy you created in the previous task is attached to the maintenance window service role you create in this task. When users register a maintenance window task, they specify this IAM role as

part of the task configuration. The permissions in this role allow Systems Manager to run tasks in maintenance windows on your behalf.

### **⚠ Important**

Previously, the Systems Manager console provided you with the ability to choose the AWS managed IAM service-linked role `AWSServiceRoleForAmazonSSM` to use as the maintenance role for your tasks. Using this role and its associated policy, `AmazonSSMServiceRolePolicy`, for maintenance window tasks is no longer recommended. If you're using this role for maintenance window tasks now, we encourage you to stop using it. Instead, create your own IAM role that enables communication between Systems Manager and other AWS services when your maintenance window tasks run.

Use the following procedure to create a custom service role for Maintenance Windows, so that Systems Manager can run Maintenance Windows tasks on your behalf. You attach the policy you created in the previous task to the custom service role you create.

### **To create a custom service role for maintenance windows using the console**

1. Open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **Roles**, and then choose **Create role**.
3. For **Select trusted entity**, make the following choices:
  1. For **Trusted entity type**, choose **AWS service**.
  2. For **Use case**, choose **Systems Manager**
  3. Choose **Systems Manager**.

The following image highlights the location of the Systems Manager option.

## Service or use case

Systems Manager

Choose a use case for the specified service.

## Use case

- Systems Manager  
Allows SSM to call AWS services on your behalf
- Systems Manager - Inventory and Maintenance Windows  
Allow AWS Systems Manager to call AWS resources on your behalf.

4. Choose **Next**.
5. In the **Permissions policies** area, in the search box, enter the name of the policy you created in [Task 1: Create a custom policy for your maintenance window service role using the console](#), select the box next to its name, and then choose **Next**.
6. For **Role name**, enter a name that identifies this role as a Maintenance Windows role. For example: **my-maintenance-window-role**.
7. (Optional) Change the default role description to reflect the purpose of this role. For example: **Performs maintenance window tasks on your behalf**.
8. For **Step 1: Select trusted entities**, verify that the following policy is displayed in the **Trusted policy** box.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "",
      "Effect": "Allow",
      "Principal": {
        "Service": "ssm.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

9. For **Step 2: Add permissions**, verify that policy you created in [Task 1: Create a custom policy for your maintenance window service role using the console](#) is present.

10. (Optional) In **Step 3: Add tags**, add one or more tag-key value pairs to organize, track, or control access for this role.
11. Choose **Create role**. The system returns you to the **Roles** page.
12. Choose the name of the IAM role you just created.
13. Copy or make a note of the role name and the **ARN** value in the **Summary** area. Users in your account specify this information when they create maintenance windows.

### Task 3: Grant permissions to specified users to register maintenance window tasks using the console

Providing users with permissions to access the custom service role for maintenance windows lets them use it with their maintenance windows tasks. This is in addition to permissions that you've already given them to work with the Systems Manager API commands for the Maintenance Windows capability. This IAM role conveys the permissions need to run a maintenance window task. As a result, a user can't register tasks with a maintenance window using your custom service role without the ability to pass these IAM permissions.

When you register a task with a maintenance window, you specify a service role to run the actual task operations. This is the role that the service assumes when it runs tasks on your behalf. Before that, to register the task itself, assign the IAM `PassRole` policy to an IAM entity (such as a user or group). This allows the IAM entity to specify, as part of registering those tasks with the maintenance window, the role that should be used when running tasks. For information, see [Grant a user permissions to pass a role to an AWS service](#) in the *IAM User Guide*.

#### To configure permissions to allow users to register maintenance window tasks

If an IAM entity (user, role, or group) is set up with administrator permissions, then the IAM user or role has access to Maintenance Windows. For IAM entities without administrator permissions, an administrator must grant the following permissions to the IAM entity. These are the minimum permissions required to register tasks with a maintenance window:

- The `AmazonSSMFullAccess` managed policy, or a policy that provides comparable permissions.
- The following `iam:PassRole` and `iam:ListRoles` permissions.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
```

```

    "Effect": "Allow",
    "Action": "iam:PassRole",
    "Resource": "arn:aws:iam::account-id:role/my-maintenance-window-role"
  },
  {
    "Effect": "Allow",
    "Action": "iam:ListRoles",
    "Resource": "arn:aws:iam::account-id:role/"
  },
  {
    "Effect": "Allow",
    "Action": "iam:ListRoles",
    "Resource": "arn:aws:iam::account-id:role/aws-service-role/
ssm.amazonaws.com/"
  }
]
}

```

*my-maintenance-window-role* represents the name of the custom maintenance window service role you created earlier.

*account-id* represents the ID of your AWS account. Adding this permission for the resource `arn:aws:iam::account-id:role/` allows a user to view and choose from customer roles in the console when they create a maintenance window task. Adding this permission for `arn:aws:iam::account-id:role/aws-service-role/ssm.amazonaws.com/` allows a user to choose the Systems Manager service-linked role in the console when they create a maintenance window task.

To provide access, add permissions to your users, groups, or roles:

- Users and groups in AWS IAM Identity Center:

Create a permission set. Follow the instructions in [Create a permission set](#) in the *AWS IAM Identity Center User Guide*.

- Users managed in IAM through an identity provider:

Create a role for identity federation. Follow the instructions in [Create a role for a third-party identity provider \(federation\)](#) in the *IAM User Guide*.

- IAM users:

- Create a role that your user can assume. Follow the instructions in [Create a role for an IAM user](#) in the *IAM User Guide*.

- (Not recommended) Attach a policy directly to a user or add a user to a user group. Follow the instructions in [Adding permissions to a user \(console\)](#) in the *IAM User Guide*.

## To configure permissions for groups that are allowed to register maintenance window tasks using the console

1. Open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **User groups**.
3. In the list of groups, select the name of the group you want to assign the `iam:PassRole` permission to, or first create a new group if necessary
4. On the **Permissions** tab, choose **Add permissions, Create inline policy**.
5. In the **Policy editor** area, choose **JSON**, and replace the default contents of the box with the following.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "iam:PassRole",
      "Resource": "arn:aws:iam::account-id:role/my-maintenance-window-role"
    },
    {
      "Effect": "Allow",
      "Action": "iam:ListRoles",
      "Resource": "arn:aws:iam::account-id:role/"
    },
    {
      "Effect": "Allow",
      "Action": "iam:ListRoles",
      "Resource": "arn:aws:iam::account-id:role/aws-service-role/
ssm.amazonaws.com/"
    }
  ]
}
```

*my-maintenance-window-role* represents the name of the custom maintenance window role you created earlier.

`account-id` represents the ID of your AWS account. Adding this permission for the resource `arn:aws:iam::account-id:role/` allows a user to view and choose from customer roles in the console when they create a maintenance window task. Adding this permission for `arn:aws:iam::account-id:role/aws-service-role/ssm.amazonaws.com/` allows a user to choose the Systems Manager service-linked role in the console when they create a maintenance window task.

6. Choose **Next**.
7. On the **Review and create** page, enter a name in the **Policy name** box to identify this PassRole policy, such as **my-group-iam-passrole-policy**, and then choose **Create policy**.

#### Task 4: Prevent specified users from registering maintenance window tasks using the console

You can deny the `ssm:RegisterTaskWithMaintenanceWindow` permission for the users in your AWS account who you don't want to register tasks with maintenance windows. This provides an extra layer of prevention for users who shouldn't register maintenance window tasks.

#### To configure permissions for groups that aren't allowed to register maintenance window tasks using the console

1. Open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **User groups**.
3. In the list of groups, select the name of the group you want to deny the `ssm:RegisterTaskWithMaintenanceWindow` permission from, or first create a new group if necessary.
4. On the **Permissions** tab, choose **Add permissions, Create inline policy**.
5. In the **Policy editor** area, choose **JSON**, and then replace the default contents of the box with the following.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Deny",
      "Action": "ssm:RegisterTaskWithMaintenanceWindow",
      "Resource": "*"
    }
  ]
}
```

```
]
}
```

6. Choose **Next**.
7. On the **Review and create** page, for **Policy name**, enter a name to identify this policy, such as **my-groups-deny-mw-tasks-policy**, and then choose **Create policy**.

## Control access to maintenance windows using the AWS CLI

The following procedures describe how to use the AWS Command Line Interface (AWS CLI) to create the required permissions and roles for Maintenance Windows, a capability of AWS Systems Manager.

### Topics

- [Task 1: Create trust policy and customer managed policy files in JSON format](#)
- [Task 2: Create and verify a custom service role for maintenance windows using the AWS CLI](#)
- [Task 3: Grant permissions to specified users to register maintenance window tasks using the AWS CLI](#)
- [Task 4: Prevent specified users from registering maintenance window tasks using the AWS CLI](#)

### Task 1: Create trust policy and customer managed policy files in JSON format

Maintenance window tasks require an IAM role to provide the permissions required to run on the target resources. The permissions are provided through an IAM policy attached to the role. The types of tasks you run and your other operational requirements determine the contents of this policy. We provide a base policy you can adapt to your needs. Depending on the tasks and types of tasks your maintenance windows run, you might not need all the permissions in this policy, and you might need to include additional permissions.

In this task, you specify the permissions needed for your custom maintenance window role in a pair of JSON files. You attach this policy to the role that you create later in [Task 2: Create and verify a custom service role for maintenance windows using the AWS CLI](#).

#### To create trust policy and customer managed policy files

1. Copy and paste the following trust policy into a text file. Save this file with the following name and file extension: **mw-role-trust-policy.json**.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": "ssm.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

2. Copy and paste the following JSON policy into a different text file. In the same directory where you created the first file, save this file with the following name and file extension: **mw-role-custom-policy.json**.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ssm:SendCommand",
        "ssm:CancelCommand",
        "ssm:ListCommands",
        "ssm:ListCommandInvocations",
        "ssm:GetCommandInvocation",
        "ssm:GetAutomationExecution",
        "ssm:StartAutomationExecution",
        "ssm:ListTagsForResource",
        "ssm:GetParameters"
      ],
      "Resource": "*"
    },
    {
      "Effect": "Allow",
      "Action": [
        "states:DescribeExecution",
        "states:StartExecution"
      ],
      "Resource": [
```

```
        "arn:aws:states:*:*:execution:*:*",
        "arn:aws:states:*:*:stateMachine:*"
    ]
},
{
    "Effect": "Allow",
    "Action": [
        "lambda:InvokeFunction"
    ],
    "Resource": [
        "arn:aws:lambda:*:*:function:*"
    ]
},
{
    "Effect": "Allow",
    "Action": [
        "resource-groups:ListGroup",
        "resource-groups:ListGroupResources"
    ],
    "Resource": [
        "*"
    ]
},
{
    "Effect": "Allow",
    "Action": [
        "tag:GetResources"
    ],
    "Resource": [
        "*"
    ]
},
{
    "Effect": "Allow",
    "Action": "iam:PassRole",
    "Resource": "*",
    "Condition": {
        "StringEquals": {
            "iam:PassedToService": [
                "ssm.amazonaws.com"
            ]
        }
    }
}
```

```
]
}
```

3. Modify the the content of `mw-role-custom-policy.json` as needed for the maintenance tasks that you run in your account. The changes you make are specific to your planned operations.

For example:

- You can provide Amazon Resource Names (ARNs) for specific functions and state machines instead of using wildcard (\*) qualifiers.
- If you don't plan to run AWS Step Functions tasks, you can remove the `states` permissions and (ARNs).
- If you don't plan to run AWS Lambda tasks, you can remove the `lambda` permissions and ARNs.
- If you don't plan to run Automation tasks, you can remove the `ssm:GetAutomationExecution` and `ssm:StartAutomationExecution` permissions.
- Add additional permissions that might be needed for the tasks to run. For example, some Automation actions work with AWS CloudFormation stacks. Therefore, the permissions `cloudformation:CreateStack`, `cloudformation:DescribeStacks`, and `cloudformation>DeleteStack` are required.

For another example, the Automation runbook `AWS-CopySnapshot` requires permissions to create an Amazon Elastic Block Store (Amazon EBS) snapshot. Therefore, the service role needs the permission `ec2:CreateSnapshot`.

For information about the role permissions needed by Automation runbooks, see the runbook descriptions in the [AWS Systems Manager Automation runbook reference](#).

Save the file again after making any needed changes.

## Task 2: Create and verify a custom service role for maintenance windows using the AWS CLI

The policy you created in the previous task is attached to the maintenance window service role you create in this task. When users register a maintenance window task, they specify this IAM role as part of the task configuration. The permissions in this role allow Systems Manager to run tasks in maintenance windows on your behalf.

**⚠ Important**

Previously, the Systems Manager console provided you with the ability to choose the AWS managed IAM service-linked role `AWSServiceRoleForAmazonSSM` to use as the maintenance role for your tasks. Using this role and its associated policy, `AmazonSSMServiceRolePolicy`, for maintenance window tasks is no longer recommended. If you're using this role for maintenance window tasks now, we encourage you to stop using it. Instead, create your own IAM role that enables communication between Systems Manager and other AWS services when your maintenance window tasks run.

In this task, you run CLI commands to create your maintenance windows service role, adding the policy content from the JSON files you created.

**Create a custom service role for maintenance windows using the AWS CLI**

1. Open the AWS CLI and run the following command in the directory where you placed `mw-role-custom-policy.json` and `mw-role-trust-policy.json`. The command creates a maintenance window service role called `my-maintenance-window-role` and attaches the *trust policy* to it.

**Linux & macOS**

```
aws iam create-role \  
  --role-name "my-maintenance-window-role" \  
  --assume-role-policy-document file://mw-role-trust-policy.json
```

**Windows**

```
aws iam create-role ^  
  --role-name "my-maintenance-window-role" ^  
  --assume-role-policy-document file://mw-role-trust-policy.json
```

The system returns information similar to the following.

```
{  
  "Role": {
```

```
"AssumeRolePolicyDocument": {
  "Version": "2012-10-17",
  "Statement": [
    {
      "Action": "sts:AssumeRole",
      "Effect": "Allow",
      "Principal": {
        "Service": "ssm.amazonaws.com"
      }
    }
  ],
  "RoleId": "AROAIIZKPBKS2LEXAMPLE",
  "CreateDate": "2024-08-19T03:40:17.373Z",
  "RoleName": "my-maintenance-window-role",
  "Path": "/",
  "Arn": "arn:aws:iam::123456789012:role/my-maintenance-window-role"
}
```

### Note

Make a note of the RoleName and the Arn values. You include them in the next command.

2. Run the following command to attach the *customer managed policy* to the role. Replace the *account-id* placeholder with your own AWS account ID

### Linux & macOS

```
aws iam attach-role-policy \
  --role-name "my-maintenance-window-role" \
  --policy-arn "arn:aws:iam::account-id:policy/mw-role-custom-policy.json"
```

### Windows

```
aws iam attach-role-policy ^
  --role-name "my-maintenance-window-role" ^
  --policy-arn "arn:aws:iam::account-id:policy/mw-role-custom-policy.json"
```

3. Run the following command to verify that your role has been created, and that the trust policy has been attached.

```
aws iam get-role --role-name my-maintenance-window-role
```

The command returns information similar to the following:

```
{
  "Role": {
    "Path": "/",
    "RoleName": "my-maintenance-window-role",
    "RoleId": "AROA123456789EXAMPLE",
    "Arn": "arn:aws:iam::123456789012:role/my-maintenance-window-role",
    "CreateDate": "2024-08-19T14:13:32+00:00",
    "AssumeRolePolicyDocument": {
      "Version": "2012-10-17",
      "Statement": [
        {
          "Effect": "Allow",
          "Principal": {
            "Service": "ssm.amazonaws.com"
          },
          "Action": "sts:AssumeRole"
        }
      ]
    },
    "MaxSessionDuration": 3600,
    "RoleLastUsed": {
      "LastUsedDate": "2024-08-19T14:30:44+00:00",
      "Region": "us-east-2"
    }
  }
}
```

4. Run the following command to verify that the customer managed policy has been attached to the role.

```
aws iam list-attached-role-policies --role-name my-maintenance-window-role
```

The command returns information similar to the following:

```
{
  "AttachedPolicies": [
    {
      "PolicyName": "mw-role-custom-policy",
      "PolicyArn": "arn:aws:iam::123456789012:policy/mw-role-custom-policy"
    }
  ]
}
```

### Task 3: Grant permissions to specified users to register maintenance window tasks using the AWS CLI

Providing users with permissions to access the custom service role for maintenance windows lets them use it with their maintenance windows tasks. This is in addition to permissions that you've already given them to work with the Systems Manager API commands for the Maintenance Windows capability. This IAM role conveys the permissions need to run a maintenance window task. As a result, a user can't register tasks with a maintenance window using your custom service role without the ability to pass these IAM permissions.

When you register a task with a maintenance window, you specify a service role to run the actual task operations. This is the role that the service assumes when it runs tasks on your behalf. Before that, to register the task itself, assign the IAM `PassRole` policy to an IAM entity (such as a user or group). This allows the IAM entity to specify, as part of registering those tasks with the maintenance window, the role that should be used when running tasks. For information, see [Grant a user permissions to pass a role to an AWS service](#) in the *IAM User Guide*.

### To configure permissions for users who are allowed to register maintenance window tasks using the AWS CLI

1. Copy and paste the following AWS Identity and Access Management (IAM) policy into a text editor and save it with the following name and file extension: `mw-passrole-policy.json`.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "iam:PassRole",
      "Resource": "arn:aws:iam::account-id:role/my-maintenance-window-role"
    }
  ]
}
```

```
    },
    {
      "Effect": "Allow",
      "Action": "iam:ListRoles",
      "Resource": "arn:aws:iam::account-id:role/"
    },
    {
      "Effect": "Allow",
      "Action": "iam:ListRoles",
      "Resource": "arn:aws:iam::account-id:role/aws-service-role/
ssm.amazonaws.com/"
    }
  ]
}
```

Replace *my-maintenance-window-role* with the name of the custom maintenance window role you created earlier.

Replace *account-id* with the ID of your AWS account. Adding this permission for the resource `arn:aws:iam::account-id:role/` allows users in the group to view and choose from customer roles in the console when they create a maintenance window task. Adding this permission for `arn:aws:iam::account-id:role/aws-service-role/ssm.amazonaws.com/` allows users in the group to choose the Systems Manager service-linked role in the console when they create a maintenance window task.

2. Open the AWS CLI.
3. Depending on whether you're assigning the permission to an IAM entity (user or group), run one of the following commands.

- **For an IAM entity:**

- Linux & macOS

```
aws iam put-user-policy \  
  --user-name "user-name" \  
  --policy-name "policy-name" \  
  --policy-document file://path-to-document
```

- Windows

```
aws iam put-user-policy ^  
  --user-name "user-name" ^
```

```
--policy-name "policy-name" ^
--policy-document file://path-to-document
```

For *user-name*, specify the user who assigns tasks to maintenance windows. For *policy-name*, specify the name you want to use to identify the policy, such as **my-iam-passrole-policy**. For *path-to-document*, specify the path to the file you saved in step 1. For example: `file://C:\Temp\mw-passrole-policy.json`

### Note

To grant access for a user to register tasks for maintenance windows using the Systems Manager console, you must also assign the AmazonSSMFullAccess policy to your user (or an IAM policy that provides a smaller set of access permissions for Systems Manager that covers maintenance window tasks). Run the following command to assign the AmazonSSMFullAccess policy to your user.

#### Linux & macOS

```
aws iam attach-user-policy \
  --policy-arn "arn:aws:iam::aws:policy/AmazonSSMFullAccess" \
  --user-name "user-name"
```

#### Windows

```
aws iam attach-user-policy ^
  --policy-arn "arn:aws:iam::aws:policy/AmazonSSMFullAccess" ^
  --user-name "user-name"
```

- **For an IAM group:**

#### Linux & macOS

```
aws iam put-group-policy \
  --group-name "group-name" \
  --policy-name "policy-name" \
  --policy-document file://path-to-document
```

#### Windows

```
aws iam put-group-policy ^
```

```
--group-name "group-name" ^  
--policy-name "policy-name" ^  
--policy-document file://path-to-document
```

For *group-name*, specify the group whose members assign tasks to maintenance windows. For *policy-name*, specify the name you want to use to identify the policy, such as **my-iam-passrole-policy**. For *path-to-document*, specify the path to the file you saved in step 1. For example: `file:///C:\Temp\mw-passrole-policy.json`

### Note

To grant access for members of a group to register tasks for maintenance windows using the Systems Manager console, you must also assign the AmazonSSMFullAccess policy to your group. Run the following command to assign this policy to your group.

#### Linux & macOS

```
aws iam attach-group-policy \  
  --policy-arn "arn:aws:iam::aws:policy/AmazonSSMFullAccess" \  
  --group-name "group-name"
```

#### Windows

```
aws iam attach-group-policy ^  
  --policy-arn "arn:aws:iam::aws:policy/AmazonSSMFullAccess" ^  
  --group-name "group-name"
```

4. Run the following command to verify that the policy has been assigned to the group.

#### Linux & macOS

```
aws iam list-group-policies \  
  --group-name "group-name"
```

#### Windows

```
aws iam list-group-policies ^  
  --group-name "group-name"
```

## Task 4: Prevent specified users from registering maintenance window tasks using the AWS CLI

You can deny the `ssm:RegisterTaskWithMaintenanceWindow` permission for the users in your AWS account who you don't want to register tasks with maintenance windows. This provides an extra layer of prevention for users who shouldn't register maintenance window tasks.

Depending on whether you're denying the `ssm:RegisterTaskWithMaintenanceWindow` permission for an individual user or a group, use one of the following procedures to prevent users from registering tasks with a maintenance window.

### To configure permissions for users who aren't allowed to register maintenance window tasks using the AWS CLI

1. Copy and paste the following IAM policy into a text editor and save it with the following name and file extension: **deny-mw-tasks-policy.json**.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Deny",
      "Action": "ssm:RegisterTaskWithMaintenanceWindow",
      "Resource": "*"
    }
  ]
}
```

2. Open the AWS CLI.
3. Depending on whether you're assigning the permission to an IAM entity (user or group), run one of the following commands.

- **For a user:**

Linux & macOS

```
aws iam put-user-policy \
  --user-name "user-name" \
  --policy-name "policy-name" \
  --policy-document file://path-to-document
```

## Windows

```
aws iam put-user-policy ^
  --user-name "user-name" ^
  --policy-name "policy-name" ^
  --policy-document file://path-to-document
```

For *user-name*, specify the user to prevent from assigning tasks to maintenance windows. For *policy-name*, specify the name you want to use to identify the policy, such as **my-deny-mw-tasks-policy**. For *path-to-document*, specify the path to the file you saved in step 1. For example: file:///C:\Temp\deny-mw-tasks-policy.json

- **For a group:**

### Linux & macOS

```
aws iam put-group-policy \
  --group-name "group-name" \
  --policy-name "policy-name" \
  --policy-document file://path-to-document
```

## Windows

```
aws iam put-group-policy ^
  --group-name "group-name" ^
  --policy-name "policy-name" ^
  --policy-document file://path-to-document
```

For *group-name*, specify the group whose to prevent from assigning tasks to maintenance windows. For *policy-name*, specify the name you want to use to identify the policy, such as **my-deny-mw-tasks-policy**. For *path-to-document*, specify the path to the file you saved in step 1. For example: file:///C:\Temp\deny-mw-tasks-policy.json

4. Run the following command to verify that the policy has been assigned to the group.

### Linux & macOS

```
aws iam list-group-policies \
  --group-name "group-name"
```

## Windows

```
aws iam list-group-policies ^  
  --group-name "group-name"
```

## Create and manage maintenance windows using the console

This section describes how to create, configure, update, and delete maintenance windows using the AWS Systems Manager console. This section also provides information about managing the targets and tasks of a maintenance window.

### Important

We recommend that you initially create and configure maintenance windows in a test environment.

## Before you begin

Before you create a maintenance window, you must configure access to Maintenance Windows, a capability of AWS Systems Manager. For more information, see [Setting up Maintenance Windows](#).

## Topics

- [Create a maintenance window using the console](#)
- [Assign targets to a maintenance window using the console](#)
- [Assign tasks to a maintenance window using the console](#)
- [Disable or enable a maintenance window using the console](#)
- [Update or delete maintenance window resources using the console](#)

## Create a maintenance window using the console

In this procedure, you create a maintenance window in Maintenance Windows, a capability of AWS Systems Manager. You can specify its basic options, such as name, schedule, and duration. In later steps, you choose the targets, or resources, that it updates and the tasks that run when the maintenance window runs.

**Note**

For an explanation of how the various schedule-related options for maintenance windows relate to one another, see [Maintenance window scheduling and active period options](#). For more information about working with the `--schedule` option, see [Reference: Cron and rate expressions for Systems Manager](#).

**To create a maintenance window using the console**

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Maintenance Windows**.
3. Choose **Create maintenance window**.
4. For **Name**, enter a descriptive name to help you identify this maintenance window.
5. (Optional) For **Description**, enter a description to identify how this maintenance window will be used.
6. (Optional) If you want to allow a maintenance window task to run on managed nodes, even if you haven't registered those nodes as targets, choose **Allow unregistered targets**.

If you choose this option, then you can choose the unregistered nodes (by node ID) when you register a task with the maintenance window.

If you don't choose this option, then you must choose previously registered targets when you register a task with the maintenance window.

7. Specify a schedule for the maintenance window by using one of the three scheduling options.

For information about building cron/rate expressions, see [Reference: Cron and rate expressions for Systems Manager](#).

8. For **Duration**, enter the number of hours the maintenance window will run. The value you specify determines the specific end time for the maintenance window based on the time it begins. No maintenance window tasks are permitted to start after the resulting endtime minus the number of hours you specify for **Stop initiating tasks** in the next step.

For example, if the maintenance window starts at 3 PM, the duration is three hours, and the **Stop initiating tasks** value is one hour, no maintenance window tasks can start after 5 PM.

9. For **Stop initiating tasks**, enter the number of hours before the end of the maintenance window that the system should stop scheduling new tasks to run.
10. (Optional) For **Window start date**, specify a date and time, in ISO-8601 Extended format, for when you want the maintenance window to become active. This allows you to delay activation of the maintenance window until the specified future date.

 **Note**

You can't specify a start date and time that occurs in the past.

11. (Optional) For **Window end date**, specify a date and time, in ISO-8601 Extended format, for when you want the maintenance window to become inactive. This allows you to set a date and time in the future after which the maintenance window no longer runs.
12. (Optional) For **Schedule timezone**, specify the time zone to use as the basis for when scheduled maintenance windows run, in Internet Assigned Numbers Authority (IANA) format. For example: "America/Los\_Angeles", "etc/UTC", or "Asia/Seoul".

For more information about valid formats, see the [Time Zone Database](#) on the IANA website.

13. (Optional) For **Schedule offset**, enter the number of days to wait after the date and time specified by a cron or rate expression before running the maintenance window. You can specify between one and six days.

 **Note**

This option is available only if you specified a schedule by entering a cron or rate expression manually.

14. (Optional) In the **Manage tags** area, apply one or more tag key name/value pairs to the maintenance window.

Tags are optional metadata that you assign to a resource. Tags allow you to categorize a resource in different ways, such as by purpose, owner, or environment. For example, you might want to tag a maintenance window to identify the type of tasks it runs, the types of targets, and the environment it runs in. In this case, you could specify the following key name/value pairs:

- Key=TaskType, Value=AgentUpdate
- Key=OS, Value=Windows

- Key=Environment, Value=Production

15. Choose **Create maintenance window**. The system returns you to the maintenance window page. The state of the maintenance window you just created is **Enabled**.

## Assign targets to a maintenance window using the console

In this procedure, you register a target with a maintenance window. In other words, you specify which resources the maintenance window performs actions on.

### Note

If a single maintenance window task is registered with multiple targets, its task invocations occur sequentially and not in parallel. If your task must run on multiple targets at the same time, register a task for each target individually and assign each task the same priority level.

## To assign targets to a maintenance window using the console

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Maintenance Windows**.
3. In the list of maintenance windows, choose the maintenance window to add targets to.
4. Choose **Actions**, and then choose **Register targets**.
5. (Optional) For **Target name**, enter a name for the targets.
6. (Optional) For **Description**, enter a description.
7. (Optional) For **Owner information**, specify information to include in any Amazon EventBridge event raised while running tasks for these targets in this maintenance window.

For information about using EventBridge to monitor Systems Manager events, see [Monitoring Systems Manager events with Amazon EventBridge](#).

8. In the **Targets** area, choose one of the options described in the following table.

| Option                           | Description   |
|----------------------------------|---|
| <b>Specify instance tags</b>     | <p>For the <b>Specify instance tags</b> boxes, specify one or more tag keys and (optional) values that have been or will be added to managed nodes in your account. When the maintenance window runs, it attempts to perform tasks on all of the managed nodes to which these tags have been added.</p> <p>If you specify more than one tag key, a node must be tagged with <i>all</i> the tag keys and values you specify to be included in the target group.</p>  |
| <b>Choose instances manually</b> | <p>From the list, select the box for each node that you want to include in the maintenance window target.</p> <p>The list includes all nodes in your account that are configured for use with Systems Manager.</p> <p>If a managed node you expect to see isn't listed, see <a href="#">Troubleshooting managed node availability</a> for troubleshooting tips.</p> <p>For edge devices and on-premises servers and virtual machines (VMs), see <a href="#">Managing nodes in hybrid and multicloud environments with Systems Manager</a></p> |

| Option                         | Description  |
|--------------------------------|--|
| <b>Choose a resource group</b> | <p>For <b>Resource group</b>, choose the name of an existing resource group in your account from the list.</p> <p>For information about creating and working with resource groups, see the following topics:</p> <ul style="list-style-type: none"><li>• <a href="#">What are resource groups?</a> in the <i>AWS Resource Groups User Guide</i></li><li>• <a href="#">Resource Groups and Tagging for AWS</a> in the <i>AWS News Blog</i></li></ul> <p>(Optional) For <b>Resource types</b>, select up to five available resource types, or choose <b>All resource types</b>.</p> <p>If the tasks you assign to the maintenance window don't act on one of the resource types you added to the target, the system might report an error. Tasks for which a supported resource type is found continue to run despite these errors.</p> <p>For example, suppose you add the following resource types to this target:</p> <ul style="list-style-type: none"><li>• <code>AWS::S3::Bucket</code></li><li>• <code>AWS::DynamoDB::Table</code></li><li>• <code>AWS::EC2::Instance</code></li></ul> <p>But later, when you add tasks to the maintenance window, you include only tasks that perform actions on nodes, such as applying a patch baseline or rebooting</p> |

| Option | Description   |
|--------|---|
|        | a node. In the maintenance window log, an error might be reported for no Amazon Simple Storage Service (Amazon S3) buckets or Amazon DynamoDB tables being found. However, the maintenance window still runs tasks on the nodes in your resource group. |

## 9. Choose **Register target**.

If you want to assign more targets to this maintenance window, choose the **Targets** tab, and then choose **Register target**. With this option, you can choose a different means of targeting. For example, if you previously targeted nodes by node ID, you can register new targets and target nodes by specifying tags applied to managed nodes or choosing resource types from a resource group.

## Assign tasks to a maintenance window using the console

In this procedure, you add a task to a maintenance window. Tasks are the actions performed when a maintenance window runs.

The following four types of tasks can be added to a maintenance window:

- AWS Systems Manager Run Command commands
- Systems Manager Automation workflows
- AWS Step Functions tasks
- AWS Lambda functions

### **Important**

The IAM policy for Maintenance Windows requires that you add the prefix SSM to Lambda function (or alias) names. Before you proceed to register this type of task, update its name in AWS Lambda to include SSM. For example, if your Lambda function name is `MyLambdaFunction`, change it to `SSMMyLambdaFunction`.

## To assign tasks to a maintenance window

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Maintenance Windows**.
3. In the list of maintenance windows, choose a maintenance window.
4. Choose **Actions**, and then choose the option for the type of task you want to register with the maintenance window.
  - **Register Run command task**
  - **Register Automation task**
  - **Register Lambda task**
  - **Register Step Functions task**

### Note

Maintenance window tasks support Step Functions Standard state machine workflows only. They don't support Express state machine workflows. For information about state machine workflow types, see [Standard vs. Express Workflows](#) in the *AWS Step Functions Developer Guide*.

5. (Optional) For **Name**, enter a name for the task.
6. (Optional) For **Description**, enter a description.
7. For **New task invocation cutoff**, if you don't want any new task invocations to start after the maintenance window cutoff time is reached, choose **Enabled**.

When this option is *not* enabled, the task continues running when the cutoff time is reached and starts new task invocations until completion.

### Note

The status for tasks that are not completed when you enable this option is `TIMED_OUT`.

8. For this step, follow the sub-steps for your selected task type.

## Run Command

1. In the **Command document** list, choose the Systems Manager Command document (SSM document) that defines the tasks to run.
2. For **Document version**, choose the document version to use.
3. For **Task priority**, specify a priority for this task. Zero (0) is the highest priority. Tasks in a maintenance window are scheduled in priority order with tasks that have the same priority scheduled in parallel.

## Automation

1. In the **Automation document** list, choose the Automation runbook that defines the tasks to run.
2. For **Document version**, choose the runbook version to use.
3. For **Task priority**, specify a priority for this task. Zero (0) is the highest priority. Tasks in a maintenance window are scheduled in priority order with tasks that have the same priority scheduled in parallel.

## Lambda

1. In the **Lambda parameters** area, choose a Lambda function from the list.
2. (Optional) Provide any content for **Payload**, **Client Context**, or **Qualifier** that you want to include.

### Note

In some cases, you can use a *pseudo parameter* as part of your Payload value. Then when the maintenance window task runs, it passes the correct values instead of the pseudo parameter placeholders. For information, see [Using pseudo parameters when registering maintenance window tasks](#).

3. For **Task priority**, specify a priority for this task. Zero (0) is the highest priority. Tasks in a maintenance window are scheduled in priority order with tasks that have the same priority scheduled in parallel.

## Step Functions

1. In the **Step Functions parameters** area, choose a state machine from the list.
2. (Optional) Provide a name for the state machine execution and any content for **Input** that you want to include.

### Note

In some cases, you can use a *pseudo parameter* as part of your Input value. Then when the maintenance window task runs, it passes the correct values instead of the pseudo parameter placeholders. For information, see [Using pseudo parameters when registering maintenance window tasks](#).

3. For **Task priority**, specify a priority for this task. Zero (0) is the highest priority. Tasks in a maintenance window are scheduled in priority order with tasks that have the same priority scheduled in parallel.
9. In the **Targets** area, choose one of the following:
    - **Selecting registered target groups:** Select one or more maintenance window targets you have registered with the current maintenance window.
    - **Selecting unregistered targets:** Choose available resources one by one as targets for the task.

If a managed node you expect to see isn't listed, see [Troubleshooting managed node availability](#) for troubleshooting tips.

- **Task target not required:** Targets for the task might already be specified in other functions for all but Run Command-type tasks.

Specify one or more targets for maintenance window Run Command-type tasks. Depending on the task, targets are optional for other maintenance window task types (Automation, AWS Lambda, and AWS Step Functions). For more information about running tasks that don't specify targets, see [Registering maintenance window tasks without targets](#).

**Note**

In many cases, you don't need to explicitly specify a target for an automation task. For example, say that you're creating an Automation-type task to update an Amazon Machine Image (AMI) for Linux using the `AWS-UpdateLinuxAmi` runbook. When the task runs, the AMI is updated with the latest available Linux distribution packages and Amazon software. New instances created from the AMI already have these updates installed. Because the ID of the AMI to be updated is specified in the input parameters for the runbook, there is no need to specify a target again in the maintenance window task.

**10. Automation tasks only:**

In the **Input parameters** area, provide values for any required or optional parameters needed to run your task.

**Note**

In some cases, you can use a *pseudo parameter* for certain input parameter values. Then when the maintenance window task runs, it passes the correct values instead of the pseudo parameter placeholders. For information, see [Using pseudo parameters when registering maintenance window tasks](#).

**11. For Rate control:**

- For **Concurrency**, specify either a number or a percentage of managed nodes on which to run the command at the same time.

**Note**

If you selected targets by specifying tags applied to managed nodes or by specifying AWS resource groups, and you aren't certain how many managed nodes are targeted, then restrict the number of targets that can run the document at the same time by specifying a percentage.

- For **Error threshold**, specify when to stop running the command on other managed nodes after it fails on either a number or a percentage of nodes. For example, if you specify three

errors, then Systems Manager stops sending the command when the fourth error is received. Managed nodes still processing the command might also send errors.

12. (Optional) For **IAM service role**, choose a role to provide permissions for Systems Manager to assume when running a maintenance window task.

If you don't specify a service role ARN, Systems Manager uses a service-linked role in your account. If no appropriate service-linked role for Systems Manager exists in your account, it's created when the task is registered successfully.

**Note**

For an improved security posture, we strongly recommend creating a custom policy and custom service role for running your maintenance window tasks. The policy can be crafted to provide only the permissions needed for your particular maintenance window tasks. For more information, see [Setting up Maintenance Windows](#).

13. *Run Command tasks only:*

(Optional) For **Output options**, do the following:

- Select the **Enable writing to S3** check box to save the command output to a file. Enter the bucket and prefix (folder) names in the boxes.
- Select the **CloudWatch output** check box to write complete output to Amazon CloudWatch Logs. Enter the name of a CloudWatch Logs log group.

**Note**

The permissions that grant the ability to write data to an S3 bucket or CloudWatch Logs are those of the instance profile assigned to the node, not those of the IAM user performing this task. For more information, see [Configure instance permissions required for Systems Manager](#). In addition, if the specified S3 bucket or log group is in a different AWS account, verify that the instance profile associated with the node has the necessary permissions to write to that bucket.

14. *Run Command tasks only:*

In the **SNS notifications** section, if you want notifications sent about the status of the command execution, select the **Enable SNS notifications** check box.

For more information about configuring Amazon SNS notifications for Run Command, see [Monitoring Systems Manager status changes using Amazon SNS notifications](#).

15. *Run Command tasks only:*

In the **Parameters** area, specify parameters for the document.

**Note**

In some cases, you can use a *pseudo parameter* for certain input parameter values. Then when the maintenance window task runs, it passes the correct values instead of the pseudo parameter placeholders. For information, see [Using pseudo parameters when registering maintenance window tasks](#).

16. *Run Command and Automation tasks only:*

(Optional) In the **CloudWatch alarm** area, for **Alarm name**, choose an existing CloudWatch alarm to apply to your task for monitoring.

If the alarm activates, the task is stopped.

**Note**

To attach a CloudWatch alarm to your task, the IAM principal that runs the task must have permission for the `iam:createServiceLinkedRole` action. For more information about CloudWatch alarms, see [Using Amazon CloudWatch alarms](#).

17. Depending on your task type, choose one of the following:

- **Register Run command task**
- **Register Automation task**
- **Register Lambda task**
- **Register Step Functions task**

## Disable or enable a maintenance window using the console

You can disable or enable a maintenance window in Maintenance Windows, a capability of AWS Systems Manager. You can choose one maintenance window at a time to either disable or enable

the maintenance window from running. You can also select multiple or all maintenance windows to enable and disable.

This section describes how to disable or enable a maintenance window by using the Systems Manager console. For examples of how to do this by using the AWS Command Line Interface (AWS CLI), see [Tutorial: Update a maintenance window using the AWS CLI](#).

## Topics

- [Disable a maintenance window using the console](#)
- [Enable a maintenance window using the console](#)

### Disable a maintenance window using the console

You can disable a maintenance window to pause a task for a specified period, and it will remain available to enable again later.

#### To disable a maintenance window

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Maintenance Windows**.
3. Using the check box next to the maintenance window that you want to disable, select one or more maintenance windows.
4. Choose **Disable maintenance window** in the **Actions** menu. The system prompts you to confirm your actions.

### Enable a maintenance window using the console

You can enable a maintenance window to resume a task.

#### Note

If the maintenance window uses a rate schedule and the start date is currently set to a past date and time, the current date and time is used as the start date for the maintenance window. You can change the start date of the maintenance window before or after enabling it. For information, see [Update or delete maintenance window resources using the console](#).

## To enable a maintenance window

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Maintenance Windows**.
3. Select the check box next to the maintenance window to enable.
4. Choose **Actions, Enable maintenance window**. The system prompts you to confirm your actions.

## Update or delete maintenance window resources using the console

You can update or delete a maintenance window in Maintenance Windows, a capability of AWS Systems Manager. You can also update or delete the targets or tasks of a maintenance window. If you edit the details of a maintenance window, you can change the schedule, targets, and tasks. You can also specify names and descriptions for windows, targets, and tasks, which helps you better understand their purpose, and makes it easier to manage your queue of windows.

This section describes how to update or delete a maintenance window, targets, and tasks by using the Systems Manager console. For examples of how to do this by using the AWS Command Line Interface (AWS CLI), see [Tutorial: Update a maintenance window using the AWS CLI](#).

## Topics

- [Updating or deleting a maintenance window using the console](#)
- [Updating or deregistering maintenance window targets using the console](#)
- [Updating or deregistering maintenance window tasks using the console](#)

## Updating or deleting a maintenance window using the console

You can update a maintenance window to change its name, description, and schedule, and whether the maintenance window should allow unregistered targets.

## To update or delete a maintenance window

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Maintenance Windows**.

3. Select the button next to the maintenance window that you want to update or delete, and then do one of the following:
  - Choose **Delete**. The system prompts you to confirm your actions.
  - Choose **Edit**. On the **Edit maintenance window** page, change the values and options that you want, and then choose **Save changes**.

For information about the configuration choices you can make, see [Create a maintenance window using the console](#).

## Updating or deregistering maintenance window targets using the console

You can update or deregister the targets of a maintenance window. If you choose to update a maintenance window target you can specify a new target name, description, and owner. You can also choose different targets.

### To update or delete the targets of a maintenance window

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Maintenance Windows**.
3. Choose the name of the maintenance window that you want to update, choose the **Targets** tab, and then do one of the following:
  - To update targets, select the button next to the target to update, and then choose **Edit**.
  - To deregister targets, select the button next to the target to deregister, and then choose **Deregister target**. In the **Deregister maintenance windows target** dialog box, choose **Deregister**.

## Updating or deregistering maintenance window tasks using the console

You can update or deregister the tasks of a maintenance window. If you choose to update, you can specify a new task name, description, and owner. For Run Command and Automation tasks, you can choose a different SSM document for the tasks. You can't, however, edit a task to change its type. For example, if you created an Automation task, you can't edit that task and change it to a Run Command task.

## To update or delete the tasks of a maintenance window using the console

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Maintenance Windows**.
3. Choose the name of the maintenance window that you want to update.
4. Choose the **Tasks** tab, and then select the button next to the task to update.
5. Do one of the following:
  - To deregister a task, choose **Deregister task**.
  - To edit the task, choose **Edit**. Change the values and options that you want, and then choose **Edit task**.

## Tutorials

The tutorials in this section show you how to perform common tasks when working with maintenance windows.

### Complete prerequisites

Before trying these tutorials, complete the following prerequisites.

- **Configure the AWS CLI on your local machine** – Before you can run AWS CLI commands, you must install and configure the CLI on your local machine. For information, see [Installing or updating the latest version of the AWS CLI](#) and [Installing the AWS Tools for PowerShell](#).
- **Verify maintenance window roles and permissions** – An AWS administrator in your account must grant you the AWS Identity and Access Management (IAM) permissions you need to manage maintenance windows using the CLI. For information, see [Setting up Maintenance Windows](#).
- **Create or configure an instance that is compatible with Systems Manager** – You need at least one Amazon Elastic Compute Cloud (Amazon EC2) instance that is configured for use with Systems Manager to complete the tutorials. This means that SSM Agent is installed on the instance, and an IAM instance profile for Systems Manager is attached to the instance.

We recommend launching an instance from one AWS managed Amazon Machine Image (AMI) with the agent preinstalled. For more information, see [Find AMIs with the SSM Agent preinstalled](#).

For information about installing SSM Agent on an instance, see the following topics:

- [Manually installing and uninstalling SSM Agent on EC2 instances for Windows Server](#)
- [Manually installing and uninstalling SSM Agent on EC2 instances for Linux](#)

For information about configuring IAM permissions for Systems Manager to your instance, see [Configure instance permissions required for Systems Manager](#).

- **Create additional resources as needed** – Run Command, a capability of Systems Manager, includes many tasks that don't require you to create resources other than those listed in this prerequisites topic. For that reason, we provide a simple Run Command task for you to use your first time through the tutorials. You also need an EC2 instance that is configured to use with Systems Manager, as described earlier in this topic. After you configure that instance, you can register a simple Run Command task.

The Systems Manager Maintenance Windows capability supports running the following four types of tasks:

- Run Command commands
- Systems Manager Automation workflows
- AWS Lambda functions
- AWS Step Functions tasks

In general, if a maintenance window task that you want to run requires additional resources, you should create them first. For example, if you want a maintenance window that runs an AWS Lambda function, create the Lambda function before you begin; for a Run Command task, create the S3 bucket that you can save command output to (if you plan to do so); and so on.

## Tutorials

- [Tutorials: Create and manage maintenance windows using the AWS CLI](#)
- [Tutorial: Create a maintenance window for patching using the console](#)

## Tutorials: Create and manage maintenance windows using the AWS CLI

This section includes tutorials that help you learn how to use the AWS Command Line Interface (AWS CLI) to do the following:

- Create and configure a maintenance window

- View information about a maintenance window
- View information about maintenance windows tasks and task executions
- Update a maintenance window
- Delete a maintenance window

## Keep track of resource IDs

As you complete the tasks in these AWS CLI tutorials, keep track of resource IDs generated by the commands you run. You use many of these as input for subsequent commands. For example, when you create the maintenance window, the system provides you with a maintenance window ID in the following format.

```
{
  "WindowId": "mw-0c50858d01EXAMPLE"
}
```

Make a note of the following system-generated IDs because the tutorials in this section use them:

- WindowId
- WindowTargetId
- WindowTaskId
- WindowExecutionId
- TaskExecutionId
- InvocationId
- ExecutionId

You also need the ID of the EC2 instance that you plan to use in the tutorials. For example:  
i-02573cafcfEXAMPLE

## Tutorials

- [Tutorial: Create and configure a maintenance window using the AWS CLI](#)
- [Tutorial: View information about maintenance windows using the AWS CLI](#)
- [Tutorial: View information about tasks and task executions using the AWS CLI](#)
- [Tutorial: Update a maintenance window using the AWS CLI](#)
- [Tutorial: Delete a maintenance window using the AWS CLI](#)

## Tutorial: Create and configure a maintenance window using the AWS CLI

This tutorial demonstrates how to use the AWS Command Line Interface (AWS CLI) to create and configure a maintenance window, its targets, and its tasks. The main path through the tutorial consists of simple steps. You create a single maintenance window, identify a single target, and set up a simple task for the maintenance window to run. Along the way, we provide information you can use to try more complicated scenarios.

As you follow the steps in this tutorial, replace the values in italicized *red* text with your own options and IDs. For example, replace the maintenance window ID *mw-0c50858d01EXAMPLE* and the instance ID *i-02573cafcfEXAMPLE* with IDs of resources you create.

### Contents

- [Step 1: Create the maintenance window using the AWS CLI](#)
- [Step 2: Register a target node with the maintenance window using the AWS CLI](#)
- [Step 3: Register a task with the maintenance window using the AWS CLI](#)

### Step 1: Create the maintenance window using the AWS CLI

In this step, you create a maintenance window and specify its basic options, such as name, schedule, and duration. In later steps, you choose the instance it updates and the task it runs.

In our example, you create a maintenance window that runs every five minutes. Normally, you wouldn't run a maintenance window this frequently. However, with this rate you can see your tutorial results quickly. We will show you how to change to a less frequent rate after the task has run successfully.

#### Note

For an explanation of how the various schedule-related options for maintenance windows relate to one another, see [Maintenance window scheduling and active period options](#). For more information about working with the `--schedule` option, see [Reference: Cron and rate expressions for Systems Manager](#).

### To create a maintenance window using the AWS CLI

1. Open the AWS Command Line Interface (AWS CLI) and run the following command on your local machine to create a maintenance window that does the following:

- Runs every five minutes for up to two hours (as needed).
- Prevents new tasks from starting within one hour of the end of the maintenance window operation.
- Allows unassociated targets (instances that you haven't registered with the maintenance window).
- Indicates through the use of custom tags that its creator intends to use it in a tutorial.

## Linux & macOS

```
aws ssm create-maintenance-window \  
  --name "My-First-Maintenance-Window" \  
  --schedule "rate(5 minutes)" \  
  --duration 2 \  
  --cutoff 1 \  
  --allow-unassociated-targets \  
  --tags "Key=Purpose,Value=Tutorial"
```

## Windows

```
aws ssm create-maintenance-window ^  
  --name "My-First-Maintenance-Window" ^  
  --schedule "rate(5 minutes)" ^  
  --duration 2 ^  
  --cutoff 1 ^  
  --allow-unassociated-targets ^  
  --tags "Key="Purpose","Value="Tutorial"
```

The system returns information similar to the following.

```
{  
  "WindowId": "mw-0c50858d01EXAMPLE"  
}
```

2. Now run the following command to view details about this and any other maintenance windows already in your account.

```
aws ssm describe-maintenance-windows
```

The system returns information similar to the following.

```
{
  "WindowIdentities":[
    {
      "WindowId": "mw-0c50858d01EXAMPLE",
      "Name": "My-First-Maintenance-Window",
      "Enabled": true,
      "Duration": 2,
      "Cutoff": 1,
      "NextExecutionTime": "2019-05-11T16:46:16.991Z"
    }
  ]
}
```

Continue to [Step 2: Register a target node with the maintenance window using the AWS CLI](#).

## Step 2: Register a target node with the maintenance window using the AWS CLI

In this step, you register a target with your new maintenance window. In this case, you specify which node to update when the maintenance window runs.

For an example of registering more than one node at a time using node IDs, examples of using tags to identify multiple nodes, and examples of specifying resource groups as targets, see [Examples: Register targets with a maintenance window](#).

### Note

You should already have created an Amazon Elastic Compute Cloud (Amazon EC2) instance to use in this step, as described in the [Maintenance Windows tutorial prerequisites](#).

## To register a target node with a maintenance window using the AWS CLI

1. Run the following command on your local machine. Replace each *example resource placeholder* with your own information.

Linux & macOS

```
aws ssm register-target-with-maintenance-window \
```

```
--window-id "mw-0c50858d01EXAMPLE" \  
--resource-type "INSTANCE" \  
--target "Key=InstanceIds,Values=i-02573cafcfEXAMPLE"
```

## Windows

```
aws ssm register-target-with-maintenance-window ^  
--window-id "mw-0c50858d01EXAMPLE" ^  
--resource-type "INSTANCE" ^  
--target "Key=InstanceIds,Values=i-02573cafcfEXAMPLE"
```

The system returns information similar to the following.

```
{  
  "WindowTargetId": "e32eeeb2-646c-4f4b-8ed1-205fbEXAMPLE"  
}
```

2. Now run the following command on your local machine to view details about your maintenance window target.

## Linux & macOS

```
aws ssm describe-maintenance-window-targets \  
--window-id "mw-0c50858d01EXAMPLE"
```

## Windows

```
aws ssm describe-maintenance-window-targets ^  
--window-id "mw-0c50858d01EXAMPLE"
```

The system returns information similar to the following.

```
{  
  "Targets": [  
    {  
      "WindowId": "mw-0c50858d01EXAMPLE",  
      "WindowTargetId": "e32eeeb2-646c-4f4b-8ed1-205fbEXAMPLE",  
      "ResourceType": "INSTANCE",  
      "Targets": [  

```

```
{
  "Key": "InstanceIds",
  "Values": [
    "i-02573cafcfEXAMPLE"
  ]
}
```

Continue to [Step 3: Register a task with the maintenance window using the AWS CLI](#).

### Examples: Register targets with a maintenance window

You can register a single node as a target using its node ID, as demonstrated in [Step 2: Register a target node with the maintenance window using the AWS CLI](#). You can also register one or more nodes as targets using the command formats on this page.

In general, there are two methods for identifying the nodes you want to use as maintenance window targets: specifying individual nodes, and using resource tags. The resource tags method provides more options, as shown in examples 2-3.

You can also specify one or more resource groups as the target of a maintenance window. A resource group can include nodes and many other types of supported AWS resources. Examples 4 and 5, next, demonstrate how to add resource groups to your maintenance window targets.

#### Note

If a single maintenance window task is registered with multiple targets, its task invocations occur sequentially and not in parallel. If your task must run on multiple targets at the same time, register a task for each target individually and assign each task the same priority level.

For more information about creating and managing resource groups, see [What are resource groups?](#) in the *AWS Resource Groups User Guide* and [Resource Groups and Tagging for AWS](#) in the *AWS News Blog*.

For information about quotas for Maintenance Windows, a capability of AWS Systems Manager, in addition to those specified in the following examples, see [Systems Manager service quotas](#) in the *Amazon Web Services General Reference*.

### Example 1: Register multiple targets using node IDs

Run the following command on your local machine format to register multiple nodes as targets using their node IDs. Replace each *example resource placeholder* with your own information.

#### Linux & macOS

```
aws ssm register-target-with-maintenance-window \  
  --window-id "mw-0c50858d01EXAMPLE" \  
  --resource-type "INSTANCE" \  
  --target  
  "Key=InstanceIds,Values=i-02573cafcfEXAMPLE,i-0471e04240EXAMPLE,i-07782c72faEXAMPLE"
```

#### Windows

```
aws ssm register-target-with-maintenance-window ^  
  --window-id "mw-0c50858d01EXAMPLE" ^  
  --resource-type "INSTANCE" ^  
  --target  
  "Key=InstanceIds,Values=i-02573cafcfEXAMPLE,i-0471e04240EXAMPLE,i-07782c72faEXAMPLE"
```

**Recommended use:** Most useful when registering a unique group of nodes with any maintenance window for the first time and they do *not* share a common node tag.

**Quotas:** You can specify up to 50 nodes total for each maintenance window target.

### Example 2: Register targets using resource tags applied to nodes

Run the following command on your local machine to register nodes that are all already tagged with a key-value pair you have assigned. Replace each *example resource placeholder* with your own information.

#### Linux & macOS

```
aws ssm register-target-with-maintenance-window \  
  --window-id "mw-0c50858d01EXAMPLE" \  
  --resource-type "INSTANCE" \  
  --target  
  "Key=InstanceIds,Values=i-02573cafcfEXAMPLE,i-0471e04240EXAMPLE,i-07782c72faEXAMPLE"
```

```
--window-id "mw-0c50858d01EXAMPLE" \  
--resource-type "INSTANCE" \  
--target "Key=tag:Region,Values=East"
```

## Windows

```
aws ssm register-target-with-maintenance-window ^  
--window-id "mw-0c50858d01EXAMPLE" ^  
--resource-type "INSTANCE" ^  
--target "Key=tag:Region,Values=East"
```

**Recommended use:** Most useful when registering a unique group of nodes with any maintenance window for the first time and they *do* share a common node tag.

**Quotas:** You can specify up to five key-value pairs total for each target. If you specify more than one key-value pair, a node must be tagged with *all* the tag keys and values you specify to be included in the target group.

### Note

You can tag a group of nodes with the tag-key `Patch Group` or `PatchGroup` and assign the nodes a common key value, such as `my-patch-group`. (You must use `PatchGroup`, without a space, if you have [allowed tags in EC2 instance metadata](#).) Patch Manager, a capability of Systems Manager, evaluates the `Patch Group` or `PatchGroup` key on nodes to help determine which patch baseline applies to them. If your task will run the `AWS-RunPatchBaseline` SSM document (or the legacy `AWS-ApplyPatchBaseline` SSM document), you can specify the same `Patch Group` or `PatchGroup` key-value pair when you register targets with a maintenance window. For example: `--target "Key=tag:PatchGroup,Values=my-patch-group".` Doing so allows you to use a maintenance window to update patches on a group of nodes that are already associated with the same patch baseline. For more information, see [Patch groups](#).

### Example 3: Register targets using a group of tag keys (without tag values)

Run the following command on your local machine to register nodes that all have one or more tag keys assigned to them, regardless of their key values. Replace each *example resource placeholder* with your own information.

## Linux & macOS

```
aws ssm register-target-with-maintenance-window \  
  --window-id "mw-0c50858d01EXAMPLE" \  
  --resource-type "INSTANCE" \  
  --target "Key=tag-key,Values=Name,Instance-Type,CostCenter"
```

## Windows

```
aws ssm register-target-with-maintenance-window ^  
  --window-id "mw-0c50858d01EXAMPLE" ^  
  --resource-type "INSTANCE" ^  
  --target "Key=tag-key,Values=Name,Instance-Type,CostCenter"
```

**Recommended use:** Useful when you want to target nodes by specifying multiple tag *keys* (without their values) rather than just one tag-key or a tag key-value pair.

**Quotas:** You can specify up to five tag-keys total for each target. If you specify more than one tag key, a node must be tagged with *all* the tag keys you specify to be included in the target group.

### Example 4: Register targets using a resource group name

Run the following command on your local machine to register a specified resource group, regardless of the type of resources it contains. Replace *mw-0c50858d01EXAMPLE* with your own information. If the tasks you assign to the maintenance window don't act on a type of resource included in this resource group, the system might report an error. Tasks for which a supported resource type is found continue to run despite these errors.

## Linux & macOS

```
aws ssm register-target-with-maintenance-window \  
  --window-id "mw-0c50858d01EXAMPLE" \  
  --resource-type "RESOURCE_GROUP" \  
  --target "Key=resource-groups:Name,Values=MyResourceGroup"
```

## Windows

```
aws ssm register-target-with-maintenance-window ^  
  --window-id "mw-0c50858d01EXAMPLE" ^  
  --resource-type "RESOURCE_GROUP" ^
```

```
--target "Key=resource-groups:Name,Values=MyResourceGroup"
```

**Recommended use:** Useful when you want to quickly specify a resource group as a target without evaluating whether all of its resource types will be targeted by a maintenance window, or when you know that the resource group contains only the resource types that your tasks perform actions on.

**Quotas:** You can specify only one resource group as a target.

### Example 5: Register targets by filtering resource types in a resource group

Run the following command on your local machine to register only certain resource types that belong to a resource group that you specify. Replace *mw-0c50858d01EXAMPLE* with your own information. With this option, even if you add a task for a resource type that belongs to the resource group, the task won't run if you haven't explicitly added the resource type to the filter.

#### Linux & macOS

```
aws ssm register-target-with-maintenance-window \  
  --window-id "mw-0c50858d01EXAMPLE" \  
  --resource-type "RESOURCE_GROUP" \  
  --target "Key=resource-groups:Name,Values=MyResourceGroup" \  
  "Key=resource-  
groups:ResourceTypeFilters,Values=AWS::EC2::Instance,AWS::ECS::Cluster"
```

#### Windows

```
aws ssm register-target-with-maintenance-window ^  
  --window-id "mw-0c50858d01EXAMPLE" ^  
  --resource-type "RESOURCE_GROUP" ^  
  --target "Key=resource-groups:Name,Values=MyResourceGroup" ^  
  "Key=resource-  
groups:ResourceTypeFilters,Values=AWS::EC2::Instance,AWS::ECS::Cluster"
```

**Recommended use:** Useful when you want to maintain strict control over the types of AWS resources your maintenance window can run actions on, or when your resource group contains a large number of resource types and you want to avoid unnecessary error reports in your maintenance window logs.

**Quotas:** You can specify only one resource group as a target.

### Step 3: Register a task with the maintenance window using the AWS CLI

In this step of the tutorial, you register an AWS Systems Manager Run Command task that runs the `df` command on your Amazon Elastic Compute Cloud (Amazon EC2) instance for Linux. The results of this standard Linux command show how much space is free and how much is used on the disk file system of your instance.

-or-

If you're targeting an Amazon EC2 instance for Windows Server instead of Linux, replace `df` in the following command with `ipconfig`. Output from this command lists details about the IP address, subnet mask, and default gateway for adapters on the target instance.

When you're ready to register other task types, or use more of the available Systems Manager Run Command options, see [Examples: Register tasks with a maintenance window](#). There, we provide more information about all four task types, and some of their most important options, to help you plan for more extensive real-world scenarios.

#### To register a task with a maintenance window

1. Run the following command on your local machine. Replace each *example resource placeholder* with your own information. The version to run from a local Windows machine includes the escape characters ("`/`") that you need to run the command from your command line tool.

##### Linux & macOS

```
aws ssm register-task-with-maintenance-window \  
  --window-id mw-0c50858d01EXAMPLE \  
  --task-arn "AWS-RunShellScript" \  
  --max-concurrency 1 --max-errors 1 \  
  --priority 10 \  
  --targets "Key=InstanceIds,Values=i-0471e04240EXAMPLE" \  
  --task-type "RUN_COMMAND" \  
  --task-invocation-parameters '{"RunCommand":{"Parameters":{"commands":  
  ["df"]}}}'
```

##### Windows

```
aws ssm register-task-with-maintenance-window ^  
  --window-id mw-0c50858d01EXAMPLE ^
```

```

--task-arn "AWS-RunShellScript" ^
--max-concurrency 1 --max-errors 1 ^
--priority 10 ^
--targets "Key=InstanceIds,Values=i-02573cafcfEXAMPLE" ^
--task-type "RUN_COMMAND" ^
--task-invocation-parameters={"RunCommand":{"Parameters":{"commands":
["df"]}}}

```

The system returns information similar to the following:

```

{
  "WindowTaskId": "4f7ca192-7e9a-40fe-9192-5cb15EXAMPLE"
}

```

- Now run the following command to view details about the maintenance window task you created.

#### Linux & macOS

```

aws ssm describe-maintenance-window-tasks \
  --window-id mw-0c50858d01EXAMPLE

```

#### Windows

```

aws ssm describe-maintenance-window-tasks ^
  --window-id mw-0c50858d01EXAMPLE

```

- The system returns information similar to the following.

```

{
  "Tasks": [
    {
      "WindowId": "mw-0c50858d01EXAMPLE",
      "WindowTaskId": "4f7ca192-7e9a-40fe-9192-5cb15EXAMPLE",
      "TaskArn": "AWS-RunShellScript",
      "Type": "RUN_COMMAND",
      "Targets": [
        {
          "Key": "InstanceIds",
          "Values": [
            "i-02573cafcfEXAMPLE"
          ]
        }
      ]
    }
  ]
}

```

```

        ]
      }
    ],
    "TaskParameters": {},
    "Priority": 10,
    "ServiceRoleArn": "arn:aws:iam::123456789012:role/
MyMaintenanceWindowServiceRole",
    "MaxConcurrency": "1",
    "MaxErrors": "1"
  }
]
}

```

4. Wait until the task has had time to run, based on the schedule you specified in [Step 1: Create the maintenance window using the AWS CLI](#). For example, if you specified `--schedule "rate(5 minutes)"`, wait five minutes. Then run the following command to view information about any executions that occurred for this task.

#### Linux & macOS

```
aws ssm describe-maintenance-window-executions \
  --window-id mw-0c50858d01EXAMPLE
```

#### Windows

```
aws ssm describe-maintenance-window-executions ^
  --window-id mw-0c50858d01EXAMPLE
```

The system returns information similar to the following.

```

{
  "WindowExecutions": [
    {
      "WindowId": "mw-0c50858d01EXAMPLE",
      "WindowExecutionId": "14bea65d-5ccc-462d-a2f3-e99c8EXAMPLE",
      "Status": "SUCCESS",
      "StartTime": 1557593493.096,
      "EndTime": 1557593498.611
    }
  ]
}

```

}

**Tip**

After the task runs successfully, you can decrease the rate at which the maintenance window runs. For example, run the following command to decrease the frequency to once a week. Replace `mw-0c50858d01EXAMPLE` with your own information.

**Linux & macOS**

```
aws ssm update-maintenance-window \  
  --window-id mw-0c50858d01EXAMPLE \  
  --schedule "rate(7 days)"
```

**Windows**

```
aws ssm update-maintenance-window ^  
  --window-id mw-0c50858d01EXAMPLE ^  
  --schedule "rate(7 days)"
```

For information about managing maintenance window schedules, see [Reference: Cron and rate expressions for Systems Manager](#) and [Maintenance window scheduling and active period options](#).

For information about using the AWS Command Line Interface (AWS CLI) to modify a maintenance window, see [Tutorial: Update a maintenance window using the AWS CLI](#).

For practice running AWS CLI commands to view more details about your maintenance window task and its executions, continue to [Tutorial: View information about tasks and task executions using the AWS CLI](#).

**Accessing tutorial command output**

It's beyond the scope of this tutorial to use the AWS CLI to view the *output* of the Run Command command associated with your maintenance window task executions.

You could view this data, however, using the AWS CLI. (You could also view the output in the Systems Manager console or in a log file stored in an Amazon Simple Storage Service (Amazon

S3) bucket, if you had configured the maintenance window to store command output there.) You would find that the output of the **df** command on an EC2 instance for Linux is similar to the following.

```
Filesystem 1K-blocks Used Available Use% Mounted on
devtmpfs 485716 0 485716 0% /dev
tmpfs 503624 0 503624 0% /dev/shm
tmpfs 503624 328 503296 1% /run
tmpfs 503624 0 503624 0% /sys/fs/cgroup
/dev/xvda1 8376300 1464160 6912140 18% /
```

The output of the **ipconfig** command on an EC2 instance for Windows Server is similar to the following:

```
Windows IP Configuration

Ethernet adapter Ethernet 2:

    Connection-specific DNS Suffix  . : example.com
    IPv4 Address. . . . . : 10.24.34.0/23
    Subnet Mask . . . . . : 255.255.255.255
    Default Gateway . . . . . : 0.0.0.0

Ethernet adapter Ethernet:

    Media State . . . . . : Media disconnected
    Connection-specific DNS Suffix  . : abc1.wa.example.net

Wireless LAN adapter Local Area Connection* 1:

    Media State . . . . . : Media disconnected
    Connection-specific DNS Suffix  . :

Wireless LAN adapter Wi-Fi:

    Connection-specific DNS Suffix  . :
    Link-local IPv6 Address . . . . . : fe80::100b:c234:66d6:d24f%4
```

```
IPv4 Address . . . . . : 192.0.2.0
Subnet Mask . . . . . : 255.255.255.0
Default Gateway . . . . . : 192.0.2.0
```

Ethernet adapter Bluetooth Network Connection:

```
Media State . . . . . : Media disconnected
Connection-specific DNS Suffix . :
```

## Examples: Register tasks with a maintenance window

You can register a task in Run Command, a capability of AWS Systems Manager, with a maintenance window using the AWS Command Line Interface (AWS CLI), as demonstrated in [Register tasks with the maintenance window](#). You can also register tasks for Systems Manager Automation workflows, AWS Lambda functions, and AWS Step Functions tasks, as demonstrated later in this topic.

### Note

Specify one or more targets for maintenance window Run Command-type tasks. Depending on the task, targets are optional for other maintenance window task types (Automation, AWS Lambda, and AWS Step Functions). For more information about running tasks that don't specify targets, see [Registering maintenance window tasks without targets](#).

In this topic, we provide examples of using the AWS Command Line Interface (AWS CLI) command `register-task-with-maintenance-window` to register each of the four supported task types with a maintenance window. The examples are for demonstration only, but you can modify them to create working task registration commands.

## Using the `--cli-input-json` option

To better manage your task options, you can use the command option `--cli-input-json`, with option values referenced in a JSON file.

To use the sample JSON file content we provide in the following examples, do the following on your local machine:

1. Create a file with a name such as `MyRunCommandTask.json`, `MyAutomationTask.json`, or another name that you prefer.

2. Copy the contents of our JSON sample into the file.
3. Modify the contents of the file for your task registration, and then save the file.
4. In the same directory where you stored the file, run the following command. Substitute your file name for *MyFile.json*.

#### Linux & macOS

```
aws ssm register-task-with-maintenance-window \  
--cli-input-json file://MyFile.json
```

#### Windows

```
aws ssm register-task-with-maintenance-window ^  
--cli-input-json file://MyFile.json
```

## Pseudo parameters in maintenance window tasks

In some examples, we use *pseudo parameters* as the method to pass ID information to your tasks. For instance, `{{TARGET_ID}}` and `{{RESOURCE_ID}}` can be used to pass IDs of AWS resources to Automation, Lambda, and Step Functions tasks. For more information about pseudo parameters in `--task-invocation-parameters` content, see [Using pseudo parameters when registering maintenance window tasks](#).

### More info

- [Parameter options for the register-task-with-maintenance-windows command](#).
- [register-task-with-maintenance-window](#) in the *AWS CLI Command Reference*
- [RegisterTaskWithMaintenanceWindow](#) in the *AWS Systems Manager API Reference*

## Task registration examples

The following sections provide a sample AWS CLI command for registering a supported task type and a JSON sample that can be used with the `--cli-input-json` option.

### Register a Systems Manager Run Command task

The following examples demonstrate how to register Systems Manager Run Command tasks with a maintenance window using the AWS CLI.

## Linux & macOS

```
aws ssm register-task-with-maintenance-window \
  --window-id mw-0c50858d01EXAMPLE \
  --task-arn "AWS-RunShellScript" \
  --max-concurrency 1 --max-errors 1 --priority 10 \
  --targets "Key=InstanceIds,Values=i-02573cafcfEXAMPLE" \
  --task-type "RUN_COMMAND" \
  --task-invocation-parameters '{"RunCommand":{"Parameters":{"commands":["df"]}}}'
```

## Windows

```
aws ssm register-task-with-maintenance-window ^
  --window-id mw-0c50858d01EXAMPLE ^
  --task-arn "AWS-RunShellScript" ^
  --max-concurrency 1 --max-errors 1 --priority 10 ^
  --targets "Key=InstanceIds,Values=i-02573cafcfEXAMPLE" ^
  --task-type "RUN_COMMAND" ^
  --task-invocation-parameters "{\"RunCommand\":{\"Parameters\":{\"commands\":["df\"]}}}"
```

## JSON content to use with --cli-input-json file option:

```
{
  "TaskType": "RUN_COMMAND",
  "WindowId": "mw-0c50858d01EXAMPLE",
  "Description": "My Run Command task to update SSM Agent on an instance",
  "MaxConcurrency": "1",
  "MaxErrors": "1",
  "Name": "My-Run-Command-Task",
  "Priority": 10,
  "Targets": [
    {
      "Key": "WindowTargetIds",
      "Values": [
        "e32eecb2-646c-4f4b-8ed1-205fbEXAMPLE"
      ]
    }
  ],
  "TaskArn": "AWS-UpdateSSMAgent",
  "TaskInvocationParameters": {
    "RunCommand": {
```

```

    "Comment": "A TaskInvocationParameters test comment",
    "NotificationConfig": {
      "NotificationArn": "arn:aws:sns:region:123456789012:my-sns-topic-name",
      "NotificationEvents": [
        "All"
      ],
      "NotificationType": "Invocation"
    },
    "OutputS3BucketName": "amzn-s3-demo-bucket",
    "OutputS3KeyPrefix": "S3-PREFIX",
    "TimeoutSeconds": 3600
  }
}
}

```

## Register a Systems Manager Automation task

The following examples demonstrate how to register Systems Manager Automation tasks with a maintenance window using the AWS CLI:

### AWS CLI command:

#### Linux & macOS

```

aws ssm register-task-with-maintenance-window \
  --window-id "mw-0c50858d01EXAMPLE" \
  --task-arn "AWS-RestartEC2Instance" \
  --service-role-arn arn:aws:iam::123456789012:role/MyMaintenanceWindowServiceRole \
  --task-type AUTOMATION \
  --task-invocation-parameters
  "Automation={DocumentVersion=5,Parameters={InstanceId='{{RESOURCE_ID}}'}}" \
  --priority 0 --name "My-Restart-EC2-Instances-Automation-Task" \
  --description "Automation task to restart EC2 instances"

```

#### Windows

```

aws ssm register-task-with-maintenance-window ^
  --window-id "mw-0c50858d01EXAMPLE" ^
  --task-arn "AWS-RestartEC2Instance" ^
  --service-role-arn arn:aws:iam::123456789012:role/MyMaintenanceWindowServiceRole
^

```

```

--task-type AUTOMATION ^
--task-invocation-parameters
"Automation={DocumentVersion=5,Parameters={InstanceId='{{TARGET_ID}}'}}" ^
--priority 0 --name "My-Restart-EC2-Instances-Automation-Task" ^
--description "Automation task to restart EC2 instances"

```

### JSON content to use with `--cli-input-json` file option:

```

{
  "WindowId": "mw-0c50858d01EXAMPLE",
  "TaskArn": "AWS-PatchInstanceWithRollback",
  "TaskType": "AUTOMATION", "TaskInvocationParameters": {
    "Automation": {
      "DocumentVersion": "1",
      "Parameters": {
        "instanceId": [
          "{{RESOURCE_ID}}"
        ]
      }
    }
  }
}

```

## Register an AWS Lambda task

The following examples demonstrate how to register Lambda function tasks with a maintenance window using the AWS CLI.

For these examples, the user who created the Lambda function named it `SSMrestart-my-instances` and created two parameters called `instanceId` and `targetType`.

### Important

The IAM policy for Maintenance Windows requires that you add the prefix `SSM` to Lambda function (or alias) names. Before you proceed to register this type of task, update its name in AWS Lambda to include `SSM`. For example, if your Lambda function name is `MyLambdaFunction`, change it to `SSMMyLambdaFunction`.

### AWS CLI command:

## Linux &amp; macOS

**⚠ Important**

If you are using version 2 of the AWS CLI, you must include the option `--cli-binary-format raw-in-base64-out` in the following command if your Lambda payload is not base64 encoded. The `cli_binary_format` option is available only in version 2. For information about this and other AWS CLI config file settings, see [Supported config file settings](#) in the *AWS Command Line Interface User Guide*.

```
aws ssm register-task-with-maintenance-window \
  --window-id "mw-0c50858d01EXAMPLE" \
  --targets "Key=WindowTargetIds,Values=e32eecb2-646c-4f4b-8ed1-205fbEXAMPLE" \
  --priority 2 --max-concurrency 10 --max-errors 5 --name "My-Lambda-Example" \
  --description "A description for my LAMBDA example task" --task-type "LAMBDA" \
  --task-arn "arn:aws:lambda:region:123456789012:function:serverlessrepo-
SSMrestart-my-instances-C4JF9EXAMPLE" \
  --task-invocation-parameters '{"Lambda":{"Payload":{"InstanceId\":"
\ "{{RESOURCE_ID}}\',"\"targetType\":"\ "{{TARGET_TYPE}}\""},\"Qualifier\": \"$LATEST\"}}'
```

## PowerShell

**⚠ Important**

If you are using version 2 of the AWS CLI, you must include the option `--cli-binary-format raw-in-base64-out` in the following command if your Lambda payload is not base64 encoded. The `cli_binary_format` option is available only in version 2. For information about this and other AWS CLI config file settings, see [Supported config file settings](#) in the *AWS Command Line Interface User Guide*.

```
aws ssm register-task-with-maintenance-window `
  --window-id "mw-0c50858d01EXAMPLE" `
  --targets "Key=WindowTargetIds,Values=e32eecb2-646c-4f4b-8ed1-205fbEXAMPLE" `
  --priority 2 --max-concurrency 10 --max-errors 5 --name "My-Lambda-Example" `
  --description "A description for my LAMBDA example task" --task-type "LAMBDA" `
  --task-arn "arn:aws:lambda:region:123456789012:function:serverlessrepo-
SSMrestart-my-instances-C4JF9EXAMPLE" `
```

```
--task-invocation-parameters '{\\"Lambda\\":{\\"Payload\\":\\"{\\"\\\\"InstanceId\\\\"":\\"\\\\"\\\\"RESOURCE_ID}\\\\""},\\"\\\\"targetType\\\\"":\\"\\\\"{\\"TARGET_TYPE}\\\\""}\\""},\\"Qualifier\\":\\"$LATEST\\"}'
```

### JSON content to use with `--cli-input-json` file option:

```
{
  "WindowId": "mw-0c50858d01EXAMPLE",
  "Targets": [
    {
      "Key": "WindowTargetIds",
      "Values": [
        "e32eecb2-646c-4f4b-8ed1-205fbEXAMPLE"
      ]
    }
  ],
  "TaskArn": "SSM_RestartMyInstances",
  "TaskType": "LAMBDA",
  "MaxConcurrency": "10",
  "MaxErrors": "10",
  "TaskInvocationParameters": {
    "Lambda": {
      "ClientContext": "ew0KICAi--truncated--0KIEXAMPLE",
      "Payload": "{ \\"instanceId\\": \\"{\\"RESOURCE_ID}\\\""}, \\"targetType\\": \\"{\\"TARGET_TYPE}\\\""}",
      "Qualifier": "$LATEST"
    }
  },
  "Name": "My-Lambda-Task",
  "Description": "A description for my LAMBDA task",
  "Priority": 5
}
```

### Register a Step Functions task

The following examples demonstrate how to register Step Functions state machine tasks with a maintenance window using the AWS CLI.

#### Note

Maintenance window tasks support Step Functions Standard state machine workflows only. They don't support Express state machine workflows. For information about state machine

workflow types, see [Standard vs. Express Workflows](#) in the *AWS Step Functions Developer Guide*.

For these examples, the user who created the Step Functions state machine created a state machine named `SSMMyStateMachine` with a parameter called `instanceId`.

### Important

The AWS Identity and Access Management (IAM) policy for Maintenance Windows requires that you prefix Step Functions state machine names with SSM. Before you proceed to register this type of task, you must update its name in AWS Step Functions to include SSM. For example, if your state machine name is `MyStateMachine`, change it to `SSMMyStateMachine`.

## AWS CLI command:

### Linux & macOS

```
aws ssm register-task-with-maintenance-window \
  --window-id "mw-0c50858d01EXAMPLE" \
  --targets "Key=WindowTargetIds,Values=e32eecb2-646c-4f4b-8ed1-205fbEXAMPLE" \
  --task-arn arn:aws:states:region:123456789012:stateMachine:SSMMyStateMachine-
MggiqEXAMPLE \
  --task-type STEP_FUNCTIONS \
  --task-invocation-parameters '{"StepFunctions":{"Input":{"\\"InstanceId\\"":
\\"{{RESOURCE_ID}}\\""}, "Name":{"\\"INVOCATION_ID}}"}' \
  --priority 0 --max-concurrency 10 --max-errors 5 \
  --name "My-Step-Functions-Task" --description "A description for my Step
Functions task"
```

### PowerShell

```
aws ssm register-task-with-maintenance-window `
  --window-id "mw-0c50858d01EXAMPLE" `
  --targets "Key=WindowTargetIds,Values=e32eecb2-646c-4f4b-8ed1-205fbEXAMPLE" `
  --task-arn arn:aws:states:region:123456789012:stateMachine:SSMMyStateMachine-
MggiqEXAMPLE `
  --task-type STEP_FUNCTIONS `
```

```
--task-invocation-parameters '{"StepFunctions\":{"Input\":"{{INSTANCE_ID}}\":"{{RESOURCE_ID}}\\\\"}, {"Name\":"{{INVOCATION_ID}}\\"}' `
--priority 0 --max-concurrency 10 --max-errors 5 `
--name "My-Step-Functions-Task" --description "A description for my Step
Functions task"
```

### JSON content to use with `--cli-input-json` file option:

```
{
  "WindowId": "mw-0c50858d01EXAMPLE",
  "Targets": [
    {
      "Key": "WindowTargetIds",
      "Values": [
        "e32eecb2-646c-4f4b-8ed1-205fbEXAMPLE"
      ]
    }
  ],
  "TaskArn": "SSM_MyStateMachine",
  "TaskType": "STEP_FUNCTIONS",
  "MaxConcurrency": "10",
  "MaxErrors": "10",
  "TaskInvocationParameters": {
    "StepFunctions": {
      "Input": "{ \"instanceId\": \"{{TARGET_ID}}\" }",
      "Name": "{{INVOCATION_ID}}"
    }
  },
  "Name": "My-Step-Functions-Task",
  "Description": "A description for my Step Functions task",
  "Priority": 5
}
```

### Parameter options for the `register-task-with-maintenance-windows` command

The `register-task-with-maintenance-window` command provides several options for configuring a task according to your needs. Some are required, some are optional, and some apply to only a single maintenance window task type.

This topic provides information about some of these options to help you work with samples in this tutorial section. For information about all command options, see [register-task-with-maintenance-window](#) in the *AWS CLI Command Reference*.

**Command option: --task-arn**

The option `--task-arn` is used to specify the resource that the task operates on. The value that you specify depends on the type of task you're registering, as described in the following table.

**TaskArn formats for maintenance window tasks**

| Maintenance window task type             | TaskArn value   |
|--|---|
| <b>RUN_COMMAND</b> and <b>AUTOMATION</b> | <p>TaskArn is the SSM document name or Amazon Resource Name (ARN). For example:</p> <pre>AWS-RunBatchShellScript</pre> <p>-or-</p> <pre>arn:aws:ssm: <i>region</i>:11112222 3333:document/My-Document .</pre>   |
| <b>LAMBDA</b>                            | <p>TaskArn is the function name or ARN. For example:</p> <pre>SSMMy-Lambda-Function</pre> <p>-or-</p> <pre>arn:aws:lambda: <i>region</i>:11112222 3333:function:SSMMyLambdaFu nction .</pre> <div data-bbox="829 1392 1507 1854" style="border: 1px solid #f08080; border-radius: 10px; padding: 10px; background-color: #fff9f9;"> <p><b>⚠ Important</b></p> <p>The IAM policy for Maintenance Windows requires that you add the prefix SSM to Lambda function (or alias) names. Before you proceed to register this type of task, update its name in AWS Lambda to include SSM. For example, if your Lambda function name is <code>MyLambdaFunction</code> ,</p> </div> |

| Maintenance window task type | TaskArn value  |
|------------------------------|--|
|                              | <div style="border: 1px solid #f08080; border-radius: 10px; padding: 10px; background-color: #fff9f9;">           change it to SSMMyLambdaFunction .         </div>  |
| <b>STEP_FUNCTIONS</b>        | <p>TaskArn is the state machine ARN. For example:</p> <pre>arn:aws:states:us-east-2:11122223333:stateMachine:SSMMyStateMachine .</pre> <div style="border: 1px solid #f08080; border-radius: 10px; padding: 10px; background-color: #fff9f9; margin-top: 10px;"> <p><b>⚠ Important</b></p> <p>The IAM policy for maintenance windows requires that you prefix Step Functions state machine names with SSM. Before you register this type of task, you must update its name in AWS Step Functions to include SSM. For example, if your state machine name is MyStateMachine , change it to SSMMyStateMachine .</p> </div> |

### Command option: `--service-role-arn`

The role for AWS Systems Manager to assume when running the maintenance window task.

For more information, see [Setting up Maintenance Windows](#)

### Command option: `--task-invocation-parameters`

The `--task-invocation-parameters` option is used to specify the parameters that are unique to each of the four task types. The supported parameters for each of the four task types are described in the following table.

**Note**

For information about using pseudo parameters in `--task-invocation-parameters` content, such as `{{TARGET_ID}}`, see [Using pseudo parameters when registering maintenance window tasks](#).

## Task invocation parameters options for maintenance window tasks

| Maintenance window task type | Available parameters   | Example  |
|------------------------------|--|--|
| RUN_COMMAND                  | Comment<br>DocumentHash<br>DocumentHashType<br>NotificationConfig<br>OutputS3BucketName<br>OutPutS3KeyPrefix<br>Parameters<br>ServiceRoleArn<br>TimeoutSeconds | <pre> "TaskInvocationParameters": {   "RunCommand": {     "Comment" : "My Run Command task comment",     "Document Hash": "6554ed3d-- truncated--5EXAMPLE",     "Document HashType": "Sha256",     "Notifica tionConfig": {        "Notifica tionArn": "arn:aws: sns: <i>region</i>:12345678 9012:my-sns-topic- name",        "NotificationEvents":       [          "FAILURE"        ],        "NotificationType":       "Invocation"     }, </pre> |

| Maintenance window task type | Available parameters | Example  |
|------------------------------|----------------------|--|
|                              |                      | <pre>       "OutputS3 BucketName": "amzn-s3- demo-bucket",       "OutputS3 KeyPrefix": "  S3-PREFIX ",       "Paramete rs": {        "commands": [        "Get-ChildItem\$env: temp-Recurse Remove- Item-Recurse-force"       ]       },       "ServiceR oleArn": "arn:aws: iam::123456789012: role/MyMaintenance WindowServiceRole",       "TimeoutS econds": 3600       }     } </pre> |

| Maintenance window task type | Available parameters                          | Example   |
|------------------------------|---|---|
| AUTOMATION                   | DocumentVersion<br><br>Parameters             | <pre> "TaskInvocationParameters": {   "Automation": {     "DocumentVersion": "3",     "Parameters": {       "instanceid": [         "{{TARGET_ID}}"       ]     }   } } </pre>  |
| LAMBDA                       | ClientContext<br><br>Payload<br><br>Qualifier | <pre> "TaskInvocationParameters": {   "Lambda": {     "ClientContext": "ew0KICAi --truncated--0KIEX AMPLE",     "Payload": "{ \"targetId\": \"{{TARGET_ID}}\", \"targetType\": \"{{TARGET_TYPE}}\" }",     "Qualifier": "\$LATEST"   } } </pre> |

| Maintenance window task type | Available parameters | Example  |
|------------------------------|----------------------|--|
| STEP_FUNCTIONS               | Input<br>Name        | <pre> "TaskInvocationParameters": {   "StepFunctions": {     "Input":       "{ \"targetId\": \"{{TARGET_ID}}\",         \"Name\": \"{{INVOCATION_ID}}\"       }     }   } </pre> |

### Tutorial: View information about maintenance windows using the AWS CLI

This tutorial includes commands to help you update or get information about your maintenance windows, tasks, executions, and invocations. The examples are organized by command to demonstrate how to use command options to filter for the type of detail you want to see.

As you follow the steps in this tutorial, replace the values in italicized *red* text with your own options and IDs. For example, replace the maintenance window ID *mw-0c50858d01EXAMPLE* and the instance ID *i-02573cafcfEXAMPLE* with IDs of resources you create.

For information about setting up and configuring the AWS Command Line Interface (AWS CLI), see [Installing, updating, and uninstalling the AWS CLI](#) and [Configuring the AWS CLI](#).

### Command examples

- [Examples for 'describe-maintenance-windows'](#)
- [Examples for 'describe-maintenance-window-targets'](#)
- [Examples for 'describe-maintenance-window-tasks'](#)
- [Examples for 'describe-maintenance-windows-for-target'](#)
- [Examples for 'describe-maintenance-window-executions'](#)
- [Examples for 'describe-maintenance-window-schedule'](#)

## Examples for 'describe-maintenance-windows'

### List all maintenance windows in your AWS account

Run the following command.

```
aws ssm describe-maintenance-windows
```

The system returns information similar to the following.

```
{
  "WindowIdentities": [
    {
      "WindowId": "mw-0c50858d01EXAMPLE",
      "Name": "My-First-Maintenance-Window",
      "Enabled": true,
      "Duration": 2,
      "Cutoff": 0,
      "NextExecutionTime": "2019-05-18T17:01:01.137Z"
    },
    {
      "WindowId": "mw-9a8b7c6d5eEXAMPLE",
      "Name": "My-Second-Maintenance-Window",
      "Enabled": true,
      "Duration": 4,
      "Cutoff": 1,
      "NextExecutionTime": "2019-05-30T03:30:00.137Z"
    }
  ]
}
```

### List all enabled maintenance windows

Run the following command.

```
aws ssm describe-maintenance-windows --filters "Key=Enabled,Values=true"
```

The system returns information similar to the following.

```
{
  "WindowIdentities": [
```

```
{
  "WindowId": "mw-0c50858d01EXAMPLE",
  "Name": "My-First-Maintenance-Window",
  "Enabled": true,
  "Duration": 2,
  "Cutoff": 0,
  "NextExecutionTime": "2019-05-18T17:01:01.137Z"
},
{
  "WindowId": "mw-9a8b7c6d5eEXAMPLE",
  "Name": "My-Second-Maintenance-Window",
  "Enabled": true,
  "Duration": 4,
  "Cutoff": 1,
  "NextExecutionTime": "2019-05-30T03:30:00.137Z"
},
]
}
```

### List all disabled maintenance windows

Run the following command.

```
aws ssm describe-maintenance-windows --filters "Key=Enabled,Values=false"
```

The system returns information similar to the following.

```
{
  "WindowIdentities": [
    {
      "WindowId": "mw-6e5c9d4b7cEXAMPLE",
      "Name": "My-Disabled-Maintenance-Window",
      "Enabled": false,
      "Duration": 2,
      "Cutoff": 1
    }
  ]
}
```

### List all maintenance windows having names that start with a certain prefix

Run the following command.

```
aws ssm describe-maintenance-windows --filters "Key=Name,Values=My"
```

The system returns information similar to the following.

```
{
  "WindowIdentities": [
    {
      "WindowId": "mw-0c50858d01EXAMPLE",
      "Name": "My-First-Maintenance-Window",
      "Enabled": true,
      "Duration": 2,
      "Cutoff": 0,
      "NextExecutionTime": "2019-05-18T17:01:01.137Z"
    },
    {
      "WindowId": "mw-9a8b7c6d5eEXAMPLE",
      "Name": "My-Second-Maintenance-Window",
      "Enabled": true,
      "Duration": 4,
      "Cutoff": 1,
      "NextExecutionTime": "2019-05-30T03:30:00.137Z"
    },
    {
      "WindowId": "mw-6e5c9d4b7cEXAMPLE",
      "Name": "My-Disabled-Maintenance-Window",
      "Enabled": false,
      "Duration": 2,
      "Cutoff": 1
    }
  ]
}
```

## Examples for 'describe-maintenance-window-targets'

### Display the targets for a maintenance window matching a specific owner information value

Run the following command.

#### Linux & macOS

```
aws ssm describe-maintenance-window-targets \
  --window-id "mw-6e5c9d4b7cEXAMPLE" \
```

```
--filters "Key=OwnerInformation,Values=CostCenter1"
```

## Windows

```
aws ssm describe-maintenance-window-targets ^  
--window-id "mw-6e5c9d4b7cEXAMPLE" ^  
--filters "Key=OwnerInformation,Values=CostCenter1"
```

### Note

The supported filter keys are Type, WindowTargetId and OwnerInformation.

The system returns information similar to the following.

```
{  
  "Targets": [  
    {  
      "WindowId": "mw-0c50858d01EXAMPLE",  
      "WindowTargetId": "e32eecb2-646c-4f4b-8ed1-205fbEXAMPLE",  
      "ResourceType": "INSTANCE",  
      "Targets": [  
        {  
          "Key": "tag:Name",  
          "Values": [  
            "Production"  
          ]  
        }  
      ],  
      "OwnerInformation": "CostCenter1",  
      "Name": "Target1"  
    }  
  ]  
}
```

## Examples for 'describe-maintenance-window-tasks'

### Show all registered tasks that invoke the SSM command document AWS-RunPowerShellScript

Run the following command.

## Linux & macOS

```
aws ssm describe-maintenance-window-tasks \
  --window-id "mw-0c50858d01EXAMPLE" \
  --filters "Key=TaskArn,Values=AWS-RunPowerShellScript"
```

## Windows

```
aws ssm describe-maintenance-window-tasks ^
  --window-id "mw-0c50858d01EXAMPLE" ^
  --filters "Key=TaskArn,Values=AWS-RunPowerShellScript"
```

The system returns information similar to the following.

```
{
  "Tasks":[
    {
      "ServiceRoleArn": "arn:aws:iam::111122223333:role/
MyMaintenanceWindowServiceRole",
      "MaxErrors":"1",
      "TaskArn":"AWS-RunPowerShellScript",
      "MaxConcurrency":"1",
      "WindowTaskId":"4f7ca192-7e9a-40fe-9192-5cb15EXAMPLE",
      "TaskParameters":{"
        "commands":{"
          "Values":[
            "driverquery.exe"
          ]
        }
      },
      "Priority":3,
      "Type":"RUN_COMMAND",
      "Targets":[
        {
          "TaskTargetId":"i-02573cafcfEXAMPLE",
          "TaskTargetType":"INSTANCE"
        }
      ]
    },
    {
      "ServiceRoleArn":"arn:aws:iam::111122223333:role/
MyMaintenanceWindowServiceRole",
```

```

    "MaxErrors": "1",
    "TaskArn": "AWS-RunPowerShellScript",
    "MaxConcurrency": "1",
    "WindowTaskId": "4f7ca192-7e9a-40fe-9192-5cb15EXAMPLE",
    "TaskParameters": {
      "commands": {
        "Values": [
          "ipconfig"
        ]
      }
    },
    "Priority": 1,
    "Type": "RUN_COMMAND",
    "Targets": [
      {
        "TaskTargetId": "i-02573cafcfEXAMPLE",
        "TaskTargetType": "WINDOW_TARGET"
      }
    ]
  }
]
}

```

## Show all registered tasks that have a priority of "3"

Run the following command.

### Linux & macOS

```

aws ssm describe-maintenance-window-tasks \
  --window-id "mw-9a8b7c6d5eEXAMPLE" \
  --filters "Key=Priority,Values=3"

```

### Windows

```

aws ssm describe-maintenance-window-tasks ^
  --window-id "mw-9a8b7c6d5eEXAMPLE" ^
  --filters "Key=Priority,Values=3"

```

The system returns information similar to the following.

```
{
```

```

    "Tasks":[
      {
        "ServiceRoleArn":"arn:aws:iam::111122223333:role/
MyMaintenanceWindowServiceRole",
        "MaxErrors":"1",
        "TaskArn":"AWS-RunPowerShellScript",
        "MaxConcurrency":"1",
        "WindowTaskId":"4f7ca192-7e9a-40fe-9192-5cb15EXAMPLE",
        "TaskParameters":{"
          "commands":{"
            "Values":[
              "driverquery.exe"
            ]
          }
        },
        "Priority":3,
        "Type":"RUN_COMMAND",
        "Targets":[
          {
            "TaskTargetId":"i-02573cafcfEXAMPLE",
            "TaskTargetType":"INSTANCE"
          }
        ]
      }
    ]
  }
}

```

## Show all registered tasks that have a priority of "1" and use Run Command

Run the following command.

### Linux & macOS

```

aws ssm describe-maintenance-window-tasks \
  --window-id "mw-0c50858d01EXAMPLE" \
  --filters "Key=Priority,Values=1" "Key=TaskType,Values=RUN_COMMAND"

```

### Windows

```

aws ssm describe-maintenance-window-tasks ^
  --window-id "mw-0c50858d01EXAMPLE" ^
  --filters "Key=Priority,Values=1" "Key=TaskType,Values=RUN_COMMAND"

```

The system returns information similar to the following.

```
{
  "Tasks": [
    {
      "WindowId": "mw-0c50858d01EXAMPLE",
      "WindowTaskId": "4f7ca192-7e9a-40fe-9192-5cb15EXAMPLE",
      "TaskArn": "AWS-RunShellScript",
      "Type": "RUN_COMMAND",
      "Targets": [
        {
          "Key": "InstanceIds",
          "Values": [
            "i-02573cafcfEXAMPLE"
          ]
        }
      ],
      "TaskParameters": {},
      "Priority": 1,
      "ServiceRoleArn": "arn:aws:iam::111122223333:role/MyMaintenanceWindowServiceRole",
      "MaxConcurrency": "1",
      "MaxErrors": "1"
    },
    {
      "WindowId": "mw-0c50858d01EXAMPLE",
      "WindowTaskId": "8a5c4629-31b0-4edd-8aea-33698EXAMPLE",
      "TaskArn": "AWS-UpdateSSMAgent",
      "Type": "RUN_COMMAND",
      "Targets": [
        {
          "Key": "InstanceIds",
          "Values": [
            "i-0471e04240EXAMPLE"
          ]
        }
      ],
      "TaskParameters": {},
      "Priority": 1,
      "ServiceRoleArn": "arn:aws:iam::111122223333:role/MyMaintenanceWindowServiceRole",
      "MaxConcurrency": "1",
      "MaxErrors": "1",
      "Name": "My-Run-Command-Task",
    }
  ]
}
```

```
        "Description": "My Run Command task to update SSM Agent on an instance"
      }
    ]
  }
}
```

## Examples for 'describe-maintenance-windows-for-target'

### List information about the maintenance window targets or tasks associated with a specific node

Run the following command.

#### Linux & macOS

```
aws ssm describe-maintenance-windows-for-target \
  --resource-type INSTANCE \
  --targets "Key=InstanceIds,Values=i-02573cafcfEXAMPLE" \
  --max-results 10
```

#### Windows

```
aws ssm describe-maintenance-windows-for-target ^
  --resource-type INSTANCE ^
  --targets "Key=InstanceIds,Values=i-02573cafcfEXAMPLE" ^
  --max-results 10
```

The system returns information similar to the following.

```
{
  "WindowIdentities": [
    {
      "WindowId": "mw-0c50858d01EXAMPLE",
      "Name": "My-First-Maintenance-Window"
    },
    {
      "WindowId": "mw-9a8b7c6d5eEXAMPLE",
      "Name": "My-Second-Maintenance-Window"
    }
  ]
}
```

## Examples for 'describe-maintenance-window-executions'

### List all tasks run before a certain date

Run the following command.

#### Linux & macOS

```
aws ssm describe-maintenance-window-executions \  
  --window-id "mw-9a8b7c6d5eEXAMPLE" \  
  --filters "Key=ExecutedBefore,Values=2019-05-12T05:00:00Z"
```

#### Windows

```
aws ssm describe-maintenance-window-executions ^  
  --window-id "mw-9a8b7c6d5eEXAMPLE" ^  
  --filters "Key=ExecutedBefore,Values=2019-05-12T05:00:00Z"
```

The system returns information similar to the following.

```
{  
  "WindowExecutions": [  
    {  
      "WindowId": "mw-0c50858d01EXAMPLE",  
      "WindowExecutionId": "14bea65d-5ccc-462d-a2f3-e99c8EXAMPLE",  
      "Status": "FAILED",  
      "StatusDetails": "The following SSM parameters are invalid: LevelUp",  
      "StartTime": 1557617747.993,  
      "EndTime": 1557617748.101  
    },  
    {  
      "WindowId": "mw-9a8b7c6d5eEXAMPLE",  
      "WindowExecutionId": "791b72e0-f0da-4021-8b35-f95dfEXAMPLE",  
      "Status": "SUCCESS",  
      "StartTime": 1557594085.428,  
      "EndTime": 1557594090.978  
    },  
    {  
      "WindowId": "mw-0c50858d01EXAMPLE",  
      "WindowExecutionId": "ecec60fa-6bb0-4d26-98c7-140308EXAMPLE",  
      "Status": "SUCCESS",  
      "StartTime": 1557593793.483,  
    }  
  ]  
}
```

```

        "EndTime": 1557593798.978
      }
    ]
  }

```

## List all tasks run after a certain date

Run the following command.

### Linux & macOS

```

aws ssm describe-maintenance-window-executions \
  --window-id "mw-9a8b7c6d5eEXAMPLE" \
  --filters "Key=ExecutedAfter,Values=2018-12-31T17:00:00Z"

```

### Windows

```

aws ssm describe-maintenance-window-executions ^
  --window-id "mw-9a8b7c6d5eEXAMPLE" ^
  --filters "Key=ExecutedAfter,Values=2018-12-31T17:00:00Z"

```

The system returns information similar to the following.

```

{
  "WindowExecutions": [
    {
      "WindowId": "mw-0c50858d01EXAMPLE",
      "WindowExecutionId": "14bea65d-5ccc-462d-a2f3-e99c8EXAMPLE",
      "Status": "FAILED",
      "StatusDetails": "The following SSM parameters are invalid: LevelUp",
      "StartTime": 1557617747.993,
      "EndTime": 1557617748.101
    },
    {
      "WindowId": "mw-9a8b7c6d5eEXAMPLE",
      "WindowExecutionId": "791b72e0-f0da-4021-8b35-f95dfEXAMPLE",
      "Status": "SUCCESS",
      "StartTime": 1557594085.428,
      "EndTime": 1557594090.978
    },
    {
      "WindowId": "mw-0c50858d01EXAMPLE",

```

```

        "WindowExecutionId": "ecec60fa-6bb0-4d26-98c7-140308EXAMPLE",
        "Status": "SUCCESS",
        "StartTime": 1557593793.483,
        "EndTime": 1557593798.978
    }
]
}

```

## Examples for 'describe-maintenance-window-schedule'

### Display the next ten scheduled maintenance window runs for a particular node

Run the following command.

#### Linux & macOS

```

aws ssm describe-maintenance-window-schedule \
  --resource-type INSTANCE \
  --targets "Key=InstanceIds,Values=i-07782c72faEXAMPLE" \
  --max-results 10

```

#### Windows

```

aws ssm describe-maintenance-window-schedule ^
  --resource-type INSTANCE ^
  --targets "Key=InstanceIds,Values=i-07782c72faEXAMPLE" ^
  --max-results 10

```

The system returns information similar to the following.

```

{
  "ScheduledWindowExecutions": [
    {
      "WindowId": "mw-0c50858d01EXAMPLE",
      "Name": "My-First-Maintenance-Window",
      "ExecutionTime": "2019-05-18T23:35:24.902Z"
    },
    {
      "WindowId": "mw-0c50858d01EXAMPLE",
      "Name": "My-First-Maintenance-Window",
      "ExecutionTime": "2019-05-25T23:35:24.902Z"
    },
  ],
}

```

```
{
  "WindowId": "mw-0c50858d01EXAMPLE",
  "Name": "My-First-Maintenance-Window",
  "ExecutionTime": "2019-06-01T23:35:24.902Z"
},
{
  "WindowId": "mw-0c50858d01EXAMPLE",
  "Name": "My-First-Maintenance-Window",
  "ExecutionTime": "2019-06-08T23:35:24.902Z"
},
{
  "WindowId": "mw-9a8b7c6d5eEXAMPLE",
  "Name": "My-Second-Maintenance-Window",
  "ExecutionTime": "2019-06-15T23:35:24.902Z"
},
{
  "WindowId": "mw-0c50858d01EXAMPLE",
  "Name": "My-First-Maintenance-Window",
  "ExecutionTime": "2019-06-22T23:35:24.902Z"
},
{
  "WindowId": "mw-9a8b7c6d5eEXAMPLE",
  "Name": "My-Second-Maintenance-Window",
  "ExecutionTime": "2019-06-29T23:35:24.902Z"
},
{
  "WindowId": "mw-0c50858d01EXAMPLE",
  "Name": "My-First-Maintenance-Window",
  "ExecutionTime": "2019-07-06T23:35:24.902Z"
},
{
  "WindowId": "mw-9a8b7c6d5eEXAMPLE",
  "Name": "My-Second-Maintenance-Window",
  "ExecutionTime": "2019-07-13T23:35:24.902Z"
},
{
  "WindowId": "mw-0c50858d01EXAMPLE",
  "Name": "My-First-Maintenance-Window",
  "ExecutionTime": "2019-07-20T23:35:24.902Z"
}
],
"NextToken": "AAEABUXdceT92FvtKld/dGHELj5Mi+GKW/EXAMPLE"
}
```

## Display the maintenance window schedule for nodes tagged with a certain key-value pair

Run the following command.

### Linux & macOS

```
aws ssm describe-maintenance-window-schedule \  
  --resource-type INSTANCE \  
  --targets "Key=tag:prod,Values=rhel7"
```

### Windows

```
aws ssm describe-maintenance-window-schedule ^  
  --resource-type INSTANCE ^  
  --targets "Key=tag:prod,Values=rhel7"
```

The system returns information similar to the following.

```
{  
  "ScheduledWindowExecutions": [  
    {  
      "WindowId": "mw-0c50858d01EXAMPLE",  
      "Name": "DemoRateStartDate",  
      "ExecutionTime": "2019-10-20T05:34:56-07:00"  
    },  
    {  
      "WindowId": "mw-0c50858d01EXAMPLE",  
      "Name": "DemoRateStartDate",  
      "ExecutionTime": "2019-10-21T05:34:56-07:00"  
    },  
    {  
      "WindowId": "mw-0c50858d01EXAMPLE",  
      "Name": "DemoRateStartDate",  
      "ExecutionTime": "2019-10-22T05:34:56-07:00"  
    },  
    {  
      "WindowId": "mw-0c50858d01EXAMPLE",  
      "Name": "DemoRateStartDate",  
      "ExecutionTime": "2019-10-23T05:34:56-07:00"  
    },  
    {  
      "WindowId": "mw-0c50858d01EXAMPLE",
```

```

        "Name": "DemoRateStartDate",
        "ExecutionTime": "2019-10-24T05:34:56-07:00"
    }
],
"NextToken": "AAEABccwSXqQRGKiTZ1yzGELR6cxW4W/EXAMPLE"
}

```

## Display start times for next four runs of a maintenance window

Run the following command.

### Linux & macOS

```

aws ssm describe-maintenance-window-schedule \
  --window-id "mw-0c50858d01EXAMPLE" \
  --max-results "4"

```

### Windows

```

aws ssm describe-maintenance-window-schedule ^
  --window-id "mw-0c50858d01EXAMPLE" ^
  --max-results "4"

```

The system returns information similar to the following.

```

{
  "WindowSchedule": [
    {
      "ScheduledWindowExecutions": [
        {
          "ExecutionTime": "2019-10-04T10:10:10Z",
          "Name": "My-First-Maintenance-Window",
          "WindowId": "mw-0c50858d01EXAMPLE"
        },
        {
          "ExecutionTime": "2019-10-11T10:10:10Z",
          "Name": "My-First-Maintenance-Window",
          "WindowId": "mw-0c50858d01EXAMPLE"
        },
        {
          "ExecutionTime": "2019-10-18T10:10:10Z",
          "Name": "My-First-Maintenance-Window",

```

```
        "WindowId": "mw-0c50858d01EXAMPLE"
      },
      {
        "ExecutionTime": "2019-10-25T10:10:10Z",
        "Name": "My-First-Maintenance-Window",
        "WindowId": "mw-0c50858d01EXAMPLE"
      }
    ]
  }
}
```

## Tutorial: View information about tasks and task executions using the AWS CLI

This tutorial demonstrates how to use the AWS Command Line Interface (AWS CLI) to view details about your completed maintenance window tasks.

If you're continuing directly from [Tutorial: Create and configure a maintenance window using the AWS CLI](#), make sure you have allowed enough time for your maintenance window to run at least once in order to see its execution results.

As you follow the steps in this tutorial, replace the values in italicized *red* text with your own options and IDs. For example, replace the maintenance window ID *mw-0c50858d01EXAMPLE* and the instance ID *i-02573cafcfEXAMPLE* with IDs of resources you create.

### To view information about tasks and task executions using the AWS CLI

1. Run the following command to view a list of task executions for a specific maintenance window.

#### Linux & macOS

```
aws ssm describe-maintenance-window-executions \  
  --window-id "mw-0c50858d01EXAMPLE"
```

#### Windows

```
aws ssm describe-maintenance-window-executions ^  
  --window-id "mw-0c50858d01EXAMPLE"
```

The system returns information similar to the following.

```
{
  "WindowExecutions": [
    {
      "WindowId": "mw-0c50858d01EXAMPLE",
      "WindowExecutionId": "14bea65d-5ccc-462d-a2f3-e99c8EXAMPLE",
      "Status": "SUCCESS",
      "StartTime": 1557593793.483,
      "EndTime": 1557593798.978
    },
    {
      "WindowId": "mw-0c50858d01EXAMPLE",
      "WindowExecutionId": "791b72e0-f0da-4021-8b35-f95dfEXAMPLE",
      "Status": "SUCCESS",
      "StartTime": 1557593493.096,
      "EndTime": 1557593498.611
    },
    {
      "WindowId": "mw-0c50858d01EXAMPLE",
      "WindowExecutionId": "ecec60fa-6bb0-4d26-98c7-140308EXAMPLE",
      "Status": "SUCCESS",
      "StatusDetails": "No tasks to execute.",
      "StartTime": 1557593193.309,
      "EndTime": 1557593193.334
    }
  ]
}
```

2. Run the following command to get information about a maintenance window task execution.

### Linux & macOS

```
aws ssm get-maintenance-window-execution \
  --window-execution-id "14bea65d-5ccc-462d-a2f3-e99c8EXAMPLE"
```

### Windows

```
aws ssm get-maintenance-window-execution ^
  --window-execution-id "14bea65d-5ccc-462d-a2f3-e99c8EXAMPLE"
```

The system returns information similar to the following.

```
{
  "WindowExecutionId": "14bea65d-5ccc-462d-a2f3-e99c8EXAMPLE",
  "TaskIds": [
    "c9b05aba-197f-4d8d-be34-e73fbEXAMPLE"
  ],
  "Status": "SUCCESS",
  "StartTime": 1557593493.096,
  "EndTime": 1557593498.611
}
```

3. Run the following command to list the tasks run as part of a maintenance window execution.

#### Linux & macOS

```
aws ssm describe-maintenance-window-execution-tasks \
  --window-execution-id "14bea65d-5ccc-462d-a2f3-e99c8EXAMPLE"
```

#### Windows

```
aws ssm describe-maintenance-window-execution-tasks ^
  --window-execution-id "14bea65d-5ccc-462d-a2f3-e99c8EXAMPLE"
```

The system returns information similar to the following.

```
{
  "WindowExecutionTaskIdentities": [
    {
      "WindowExecutionId": "14bea65d-5ccc-462d-a2f3-e99c8EXAMPLE",
      "TaskExecutionId": "c9b05aba-197f-4d8d-be34-e73fbEXAMPLE",
      "Status": "SUCCESS",
      "StartTime": 1557593493.162,
      "EndTime": 1557593498.57,
      "TaskArn": "AWS-RunShellScript",
      "TaskType": "RUN_COMMAND"
    }
  ]
}
```

4. Run the following command to get the details of a task execution.

## Linux & macOS

```
aws ssm get-maintenance-window-execution-task \  
  --window-execution-id "14bea65d-5ccc-462d-a2f3-e99c8EXAMPLE" \  
  --task-id "c9b05aba-197f-4d8d-be34-e73fbEXAMPLE"
```

## Windows

```
aws ssm get-maintenance-window-execution-task ^  
  --window-execution-id "14bea65d-5ccc-462d-a2f3-e99c8EXAMPLE" ^  
  --task-id "c9b05aba-197f-4d8d-be34-e73fbEXAMPLE"
```

The system returns information similar to the following.

```
{  
  "WindowExecutionId": "14bea65d-5ccc-462d-a2f3-e99c8EXAMPLE",  
  "TaskExecutionId": "c9b05aba-197f-4d8d-be34-e73fbEXAMPLE",  
  "TaskArn": "AWS-RunShellScript",  
  "ServiceRole": "arn:aws:iam::111122223333:role/MyMaintenanceWindowServiceRole",  
  "Type": "RUN_COMMAND",  
  "TaskParameters": [  
    {  
      "aws:InstanceId": {  
        "Values": [  
          "i-02573cafcfEXAMPLE"  
        ]  
      },  
      "commands": {  
        "Values": [  
          "df"  
        ]  
      }  
    }  
  ],  
  "Priority": 10,  
  "MaxConcurrency": "1",  
  "MaxErrors": "1",  
  "Status": "SUCCESS",  
  "StartTime": 1557593493.162,  
  "EndTime": 1557593498.57
```

```
}

```

5. Run the following command to get the specific task invocations performed for a task execution.

### Linux & macOS

```
aws ssm describe-maintenance-window-execution-task-invocations \
  --window-execution-id "14bea65d-5ccc-462d-a2f3-e99c8EXAMPLE" \
  --task-id "c9b05aba-197f-4d8d-be34-e73fbEXAMPLE"
```

### Windows

```
aws ssm describe-maintenance-window-execution-task-invocations ^
  --window-execution-id "14bea65d-5ccc-462d-a2f3-e99c8EXAMPLE" ^
  --task-id "c9b05aba-197f-4d8d-be34-e73fbEXAMPLE"
```

The system returns information similar to the following.

```
{
  "WindowExecutionTaskInvocationIdentities": [
    {
      "WindowExecutionId": "14bea65d-5ccc-462d-a2f3-e99c8EXAMPLE",
      "TaskExecutionId": "c9b05aba-197f-4d8d-be34-e73fbEXAMPLE",
      "InvocationId": "c336d2ab-09de-44ba-8f6a-6136cEXAMPLE",
      "ExecutionId": "76a5a04f-caf6-490c-b448-92c02EXAMPLE",
      "TaskType": "RUN_COMMAND",
      "Parameters": "{\"documentName\":\"AWS-RunShellScript\",\"instanceIds\":"
      "\":[\"i-02573cafcfEXAMPLE\"],\"maxConcurrency\":\"1\",\"maxErrors\":\"1\",
      \"parameters\":{\"commands\":[\"df\"]}}",
      "Status": "SUCCESS",
      "StatusDetails": "Success",
      "StartTime": 1557593493.222,
      "EndTime": 1557593498.466
    }
  ]
}
```

## Tutorial: Update a maintenance window using the AWS CLI

This tutorial demonstrates how to use the AWS Command Line Interface (AWS CLI) to update a maintenance window. It also shows you how to update different task types, including those for AWS Systems Manager Run Command and Automation, AWS Lambda, and AWS Step Functions.

The examples in this section use the following Systems Manager actions for updating a maintenance window:

- [UpdateMaintenanceWindow](#)
- [UpdateMaintenanceWindowTarget](#)
- [UpdateMaintenanceWindowTask](#)
- [DeregisterTargetFromMaintenanceWindow](#)

For information about using the Systems Manager console to update a maintenance window, see [Update or delete maintenance window resources using the console](#).

As you follow the steps in this tutorial, replace the values in italicized *red* text with your own options and IDs. For example, replace the maintenance window ID *mw-0c50858d01EXAMPLE* and the instance ID *i-02573cafcfEXAMPLE* with IDs of resources you create.

### To update a maintenance window using the AWS CLI

1. Open the AWS CLI and run the following command to update a target to include a name and a description.

#### Linux & macOS

```
aws ssm update-maintenance-window-target \  
  --window-id "mw-0c50858d01EXAMPLE" \  
  --window-target-id "e32eecb2-646c-4f4b-8ed1-205fbEXAMPLE" \  
  --name "My-Maintenance-Window-Target" \  
  --description "Description for my maintenance window target"
```

#### Windows

```
aws ssm update-maintenance-window-target ^  
  --window-id "mw-0c50858d01EXAMPLE" ^  
  --window-target-id "e32eecb2-646c-4f4b-8ed1-205fbEXAMPLE" ^
```

```
--name "My-Maintenance-Window-Target" ^
--description "Description for my maintenance window target"
```

The system returns information similar to the following.

```
{
  "WindowId": "mw-0c50858d01EXAMPLE",
  "WindowTargetId": "e32eecb2-646c-4f4b-8ed1-205fbEXAMPLE",
  "Targets": [
    {
      "Key": "InstanceIds",
      "Values": [
        "i-02573cafcfEXAMPLE"
      ]
    }
  ],
  "Name": "My-Maintenance-Window-Target",
  "Description": "Description for my maintenance window target"
}
```

2. Run the following command to use the `replace` option to remove the description field and add an additional target. The description field is removed, because the update doesn't include the field (a null value). Be sure to specify an additional node that has been configured for use with Systems Manager.

## Linux & macOS

```
aws ssm update-maintenance-window-target \
  --window-id "mw-0c50858d01EXAMPLE" \
  --window-target-id "d208dedf-3f6b-41ff-ace8-8e751EXAMPLE" \
  --targets "Key=InstanceIds,Values=i-02573cafcfEXAMPLE,i-0471e04240EXAMPLE" \
  --name "My-Maintenance-Window-Target" \
  --replace
```

## Windows

```
aws ssm update-maintenance-window-target ^
  --window-id "mw-0c50858d01EXAMPLE" ^
  --window-target-id "d208dedf-3f6b-41ff-ace8-8e751EXAMPLE" ^
  --targets "Key=InstanceIds,Values=i-02573cafcfEXAMPLE,i-0471e04240EXAMPLE" ^
  --name "My-Maintenance-Window-Target" ^
```

```
--replace
```

The system returns information similar to the following.

```
{
  "WindowId": "mw-0c50858d01EXAMPLE",
  "WindowTargetId": "e32eecb2-646c-4f4b-8ed1-205fbEXAMPLE",
  "Targets": [
    {
      "Key": "InstanceIds",
      "Values": [
        "i-02573cafcfEXAMPLE",
        "i-0471e04240EXAMPLE"
      ]
    }
  ],
  "Name": "My-Maintenance-Window-Target"
}
```

- The `start-date` option allows you to delay activation of a maintenance window until a specified future date. The `end-date` option allows you to set a date and time in the future after which the maintenance window no longer runs. Specify the options in ISO-8601 Extended format.

Run the following command to specify a date and time range for regularly scheduled maintenance window executions.

#### Linux & macOS

```
aws ssm update-maintenance-window \
  --window-id "mw-0c50858d01EXAMPLE" \
  --start-date "2020-10-01T10:10:10Z" \
  --end-date "2020-11-01T10:10:10Z"
```

#### Windows

```
aws ssm update-maintenance-window ^
  --window-id "mw-0c50858d01EXAMPLE" ^
  --start-date "2020-10-01T10:10:10Z" ^
  --end-date "2020-11-01T10:10:10Z"
```

#### 4. Run the following command to update a Run Command task.

##### Tip

If your target is an Amazon Elastic Compute Cloud (Amazon EC2) instance for Windows Server, change `df` to `ipconfig`, and `AWS-RunShellScript` to `AWS-RunPowerShellScript` in the following command.

### Linux & macOS

```
aws ssm update-maintenance-window-task \
  --window-id "mw-0c50858d01EXAMPLE" \
  --window-task-id "4f7ca192-7e9a-40fe-9192-5cb15EXAMPLE" \
  --targets "Key=WindowTargetIds,Values=e32eecb2-646c-4f4b-8ed1-205fbEXAMPLE" \
  \
  --task-arn "AWS-RunShellScript" \
  --service-role-arn "arn:aws:iam::account-id:role/MaintenanceWindowsRole" \
  --task-invocation-parameters "RunCommand={Comment=Revising my Run Command
task,Parameters={commands=df}}" \
  --priority 1 --max-concurrency 10 --max-errors 4 \
  --name "My-Task-Name" --description "A description for my Run Command task"
```

### Windows

```
aws ssm update-maintenance-window-task ^
  --window-id "mw-0c50858d01EXAMPLE" ^
  --window-task-id "4f7ca192-7e9a-40fe-9192-5cb15EXAMPLE" ^
  --targets "Key=WindowTargetIds,Values=e32eecb2-646c-4f4b-8ed1-205fbEXAMPLE"
^
  --task-arn "AWS-RunShellScript" ^
  --service-role-arn "arn:aws:iam::account-id:role/MaintenanceWindowsRole" ^
  --task-invocation-parameters "RunCommand={Comment=Revising my Run Command
task,Parameters={commands=df}}" ^
  --priority 1 --max-concurrency 10 --max-errors 4 ^
  --name "My-Task-Name" --description "A description for my Run Command task"
```

The system returns information similar to the following.

```
{
```

```

"WindowId": "mw-0c50858d01EXAMPLE",
"WindowTaskId": "4f7ca192-7e9a-40fe-9192-5cb15EXAMPLE",
"Targets": [
  {
    "Key": "WindowTargetIds",
    "Values": [
      "e32eecb2-646c-4f4b-8ed1-205fbEXAMPLE"
    ]
  }
],
"TaskArn": "AWS-RunShellScript",
"ServiceRoleArn": "arn:aws:iam::111122223333:role/MaintenanceWindowsRole",
"TaskParameters": {},
"TaskInvocationParameters": {
  "RunCommand": {
    "Comment": "Revising my Run Command task",
    "Parameters": {
      "commands": [
        "df"
      ]
    }
  }
},
"Priority": 1,
"MaxConcurrency": "10",
"MaxErrors": "4",
"Name": "My-Task-Name",
>Description": "A description for my Run Command task"
}

```

5. Adapt and run the following command to update a Lambda task.

### Linux & macOS

```

aws ssm update-maintenance-window-task \
  --window-id mw-0c50858d01EXAMPLE \
  --window-task-id 4f7ca192-7e9a-40fe-9192-5cb15EXAMPLE \
  --targets "Key=WindowTargetIds,Values=e32eecb2-646c-4f4b-8ed1-205fbEXAMPLE" \
  --task-arn "arn:aws:lambda:region:111122223333:function:SSMTestLambda" \
  --service-role-arn "arn:aws:iam:account-id:role/MaintenanceWindowsRole" \
  --task-invocation-parameters '{"Lambda":{"Payload":{"InstanceId": \
  \{"{RESOURCE_ID}\",\{"targetType\":"\{"{TARGET_TYPE}\}\\"}}}' \
  --priority 1 --max-concurrency 10 --max-errors 5 \

```

```
--name "New-Lambda-Task-Name" \  
--description "A description for my Lambda task"
```

## Windows

```
aws ssm update-maintenance-window-task ^  
  --window-id mw-0c50858d01EXAMPLE ^  
  --window-task-id 4f7ca192-7e9a-40fe-9192-5cb15EXAMPLE ^  
  --targets "Key=WindowTargetIds,Values=e32eecb2-646c-4f4b-8ed1-205fbEXAMPLE"  
  ^  
  --task-arn --task-arn  
  "arn:aws:lambda:region:111122223333:function:SSMTestLambda" ^  
  --service-role-arn "arn:aws:iam:account-id:role/MaintenanceWindowsRole" ^  
  --task-invocation-parameters '{"Lambda":{"Payload":"{\"InstanceId\":  
\"{{RESOURCE_ID}}\", \"targetType\": \"{{TARGET_TYPE}}\"}}' ^  
  --priority 1 --max-concurrency 10 --max-errors 5 ^  
  --name "New-Lambda-Task-Name" ^  
  --description "A description for my Lambda task"
```

The system returns information similar to the following.

```
{  
  "WindowId": "mw-0c50858d01EXAMPLE",  
  "WindowTaskId": "4f7ca192-7e9a-40fe-9192-5cb15EXAMPLE",  
  "Targets": [  
    {  
      "Key": "WindowTargetIds",  
      "Values": "e32eecb2-646c-4f4b-8ed1-205fbEXAMPLE"  
    }  
  ],  
  "TaskArn": "arn:aws:lambda:us-east-2:111122223333:function:SSMTestLambda",  
  "ServiceRoleArn": "arn:aws:iam::111122223333:role/MaintenanceWindowsRole",  
  "TaskParameters": {},  
  "TaskInvocationParameters": {  
    "Lambda": {  
      "Payload": "e30="    }  
  },  
  "Priority": 1,  
  "MaxConcurrency": "10",  
  "MaxErrors": "5",  
  "Name": "New-Lambda-Task-Name",
```

```

    "Description": "A description for my Lambda task"
  }

```

6. If you're updating a Step Functions task, adapt and run the following command to update its task-invocation-parameters.

### Linux & macOS

```

aws ssm update-maintenance-window-task \
  --window-id "mw-0c50858d01EXAMPLE" \
  --window-task-id "4f7ca192-7e9a-40fe-9192-5cb15EXAMPLE" \
  --targets "Key=WindowTargetIds,Values=e32eecb2-646c-4f4b-8ed1-205fbEXAMPLE" \
  \
  --task-arn "arn:aws:states:region:execution:SSMStepFunctionTest" \
  --service-role-arn "arn:aws:iam:account-id:role/MaintenanceWindowsRole" \
  --task-invocation-parameters '{"StepFunctions":{"Input":{"InstanceId\":"\
  \{{RESOURCE_ID}}\\"}}}' \
  --priority 0 --max-concurrency 10 --max-errors 5 \
  --name "My-Step-Functions-Task" \
  --description "A description for my Step Functions task"

```

### Windows

```

aws ssm update-maintenance-window-task ^
  --window-id "mw-0c50858d01EXAMPLE" ^
  --window-task-id "4f7ca192-7e9a-40fe-9192-5cb15EXAMPLE" ^
  --targets "Key=WindowTargetIds,Values=e32eecb2-646c-4f4b-8ed1-205fbEXAMPLE" ^
  ^
  --task-arn "arn:aws:states:region:execution:SSMStepFunctionTest" ^
  --service-role-arn "arn:aws:iam:account-id:role/MaintenanceWindowsRole" ^
  --task-invocation-parameters '{"StepFunctions":{"Input":{"InstanceId\":"\
  \{{RESOURCE_ID}}\\"}}}' ^
  --priority 0 --max-concurrency 10 --max-errors 5 ^
  --name "My-Step-Functions-Task" ^
  --description "A description for my Step Functions task"

```

The system returns information similar to the following.

```

{
  "WindowId": "mw-0c50858d01EXAMPLE",
  "WindowTaskId": "4f7ca192-7e9a-40fe-9192-5cb15EXAMPLE",

```

```

    "Targets": [
      {
        "Key": "WindowTargetIds",
        "Values": [
          "e32eecb2-646c-4f4b-8ed1-205fbEXAMPLE"
        ]
      }
    ],
    "TaskArn": "arn:aws:states:us-
east-2:111122223333:execution:SSMStepFunctionTest",
    "ServiceRoleArn": "arn:aws:iam::111122223333:role/MaintenanceWindowsRole",
    "TaskParameters": {},
    "TaskInvocationParameters": {
      "StepFunctions": {
        "Input": "{\\"instanceId\\":\\"{{RESOURCE_ID}}\\"}"
      }
    },
    "Priority": 0,
    "MaxConcurrency": "10",
    "MaxErrors": "5",
    "Name": "My-Step-Functions-Task",
    "Description": "A description for my Step Functions task"
  }

```

7. Run the following command to unregister a target from a maintenance window. This example uses the `safe` parameter to determine if the target is referenced by any tasks and therefore safe to unregister.

### Linux & macOS

```

aws ssm deregister-target-from-maintenance-window \
  --window-id "mw-0c50858d01EXAMPLE" \
  --window-target-id "e32eecb2-646c-4f4b-8ed1-205fbEXAMPLE" \
  --safe

```

### Windows

```

aws ssm deregister-target-from-maintenance-window ^
  --window-id "mw-0c50858d01EXAMPLE" ^
  --window-target-id "e32eecb2-646c-4f4b-8ed1-205fbEXAMPLE" ^
  --safe

```

The system returns information similar to the following.

```
An error occurred (TargetInUseException) when calling the
DeregisterTargetFromMaintenanceWindow operation:
This Target cannot be deregistered because it is still referenced in Task:
4f7ca192-7e9a-40fe-9192-5cb15EXAMPLE
```

8. Run the following command to unregister a target from a maintenance window even if the target is referenced by a task. You can force the unregister operation by using the `no-safe` parameter.

### Linux & macOS

```
aws ssm deregister-target-from-maintenance-window \
  --window-id "mw-0c50858d01EXAMPLE" \
  --window-target-id "e32eecb2-646c-4f4b-8ed1-205fbEXAMPLE" \
  --no-safe
```

### Windows

```
aws ssm deregister-target-from-maintenance-window ^
  --window-id "mw-0c50858d01EXAMPLE" ^
  --window-target-id "e32eecb2-646c-4f4b-8ed1-205fbEXAMPLE" ^
  --no-safe
```

The system returns information similar to the following.

```
{
  "WindowId": "mw-0c50858d01EXAMPLE",
  "WindowTargetId": "e32eecb2-646c-4f4b-8ed1-205fbEXAMPLE"
}
```

9. Run the following command to update a Run Command task. This example uses a Systems Manager Parameter Store parameter called `UpdateLevel`, which is formatted as follows: `'{{ssm:UpdateLevel}}'`

## Linux & macOS

```
aws ssm update-maintenance-window-task \
  --window-id "mw-0c50858d01EXAMPLE" \
  --window-task-id "4f7ca192-7e9a-40fe-9192-5cb15EXAMPLE" \
  --targets "Key=InstanceIds,Values=i-02573cafcfEXAMPLE" \
  --task-invocation-parameters "RunCommand={Comment=A comment for my task
  update,Parameters={UpdateLevel='{{ssm:UpdateLevel}}'}"}"
```

## Windows

```
aws ssm update-maintenance-window-task ^
  --window-id "mw-0c50858d01EXAMPLE" ^
  --window-task-id "4f7ca192-7e9a-40fe-9192-5cb15EXAMPLE" ^
  --targets "Key=InstanceIds,Values=i-02573cafcfEXAMPLE" ^
  --task-invocation-parameters "RunCommand={Comment=A comment for my task
  update,Parameters={UpdateLevel='{{ssm:UpdateLevel}}'}"}"
```

The system returns information similar to the following.

```
{
  "WindowId": "mw-0c50858d01EXAMPLE",
  "WindowTaskId": "4f7ca192-7e9a-40fe-9192-5cb15EXAMPLE",
  "Targets": [
    {
      "Key": "InstanceIds",
      "Values": [
        "i-02573cafcfEXAMPLE"
      ]
    }
  ],
  "TaskArn": "AWS-RunShellScript",
  "ServiceRoleArn": "arn:aws:iam::111122223333:role/
  MyMaintenanceWindowServiceRole",
  "TaskParameters": {},
  "TaskInvocationParameters": {
    "RunCommand": {
      "Comment": "A comment for my task update",
      "Parameters": {
        "UpdateLevel": [
```

```

        "{{ssm:UpdateLevel}}"
    ]
}
},
"Priority": 10,
"MaxConcurrency": "1",
"MaxErrors": "1"
}

```

10. Run the following command to update an Automation task to specify WINDOW\_ID and WINDOW\_TASK\_ID parameters for the task-invocation-parameters parameter:

### Linux & macOS

```

aws ssm update-maintenance-window-task \
  --window-id "mw-0c50858d01EXAMPLE" \
  --window-task-id "4f7ca192-7e9a-40fe-9192-5cb15EXAMPLE" \
  --targets "Key=WindowTargetIds,Values=e32eecb2-646c-4f4b-8ed1-205fbEXAMPLE" \
  --task-arn "AutoTestDoc" \
  --service-role-arn "arn:aws:iam:account-id:role/
MyMaintenanceWindowServiceRole \
  --task-invocation-parameters
"Automation={Parameters={InstanceId='{{RESOURCE_ID}}',initiator='{{WINDOW_ID}}.Task-
{{WINDOW_TASK_ID}}'}" \
  --priority 3 --max-concurrency 10 --max-errors 5

```

### Windows

```

aws ssm update-maintenance-window-task ^
  --window-id "mw-0c50858d01EXAMPLE" ^
  --window-task-id "4f7ca192-7e9a-40fe-9192-5cb15EXAMPLE" ^
  --targets "Key=WindowTargetIds,Values=e32eecb2-646c-4f4b-8ed1-205fbEXAMPLE" ^
  --task-arn "AutoTestDoc" ^
  --service-role-arn "arn:aws:iam:account-id:role/
MyMaintenanceWindowServiceRole ^
  --task-invocation-parameters
"Automation={Parameters={InstanceId='{{RESOURCE_ID}}',initiator='{{WINDOW_ID}}.Task-
{{WINDOW_TASK_ID}}'}" ^
  --priority 3 --max-concurrency 10 --max-errors 5

```

The system returns information similar to the following.

```
{
  "WindowId": "mw-0c50858d01EXAMPLE",
  "WindowTaskId": "4f7ca192-7e9a-40fe-9192-5cb15EXAMPLE",
  "Targets": [
    {
      "Key": "WindowTargetIds",
      "Values": [
        "e32eecb2-646c-4f4b-8ed1-205fbEXAMPLE"
      ]
    }
  ],
  "TaskArn": "AutoTestDoc",
  "ServiceRoleArn": "arn:aws:iam::111122223333:role/MyMaintenanceWindowServiceRole",
  "TaskParameters": {},
  "TaskInvocationParameters": {
    "Automation": {
      "Parameters": {
        "multi": [
          "{{WINDOW_TASK_ID}}"
        ],
        "single": [
          "{{WINDOW_ID}}"
        ]
      }
    }
  },
  "Priority": 0,
  "MaxConcurrency": "10",
  "MaxErrors": "5",
  "Name": "My-Automation-Task",
  "Description": "A description for my Automation task"
}
```

## Tutorial: Delete a maintenance window using the AWS CLI

To delete a maintenance window you created in these tutorials, run the following command.

```
aws ssm delete-maintenance-window --window-id "mw-0c50858d01EXAMPLE"
```

The system returns information similar to the following.

```
{
  "WindowId": "mw-0c50858d01EXAMPLE"
}
```

## Tutorial: Create a maintenance window for patching using the console

### Important

You can continue to use this legacy topic to create a maintenance window for patching. However, we recommend that you use a patch policy instead. For more information, see [Patch policy configurations in Quick Setup](#) and [Configure patching for instances in an organization using Quick Setup](#).

To minimize the impact on your server availability, we recommend that you configure a maintenance window to run patching during times that won't interrupt your business operations.

You must configure roles and permissions for Maintenance Windows, a capability of AWS Systems Manager, before beginning this procedure. For more information, see [Setting up Maintenance Windows](#).

### To create a maintenance window for patching

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Maintenance Windows**.
3. Choose **Create maintenance window**.
4. For **Name**, enter a name that designates this as a maintenance window for patching critical and important updates.
5. (Optional) For **Description**, enter a description.
6. Choose **Allow unregistered targets** if you want to allow a maintenance window task to run on managed nodes, even if you haven't registered those nodes as targets.

If you choose this option, then you can choose the unregistered nodes (by node ID) when you register a task with the maintenance window.

If you don't choose this option, then you must choose previously-registered targets when you register a task with the maintenance window.

7. In the top of the **Schedule** section, specify a schedule for the maintenance window by using one of the three scheduling options.

For information about building cron/rate expressions, see [Reference: Cron and rate expressions for Systems Manager](#).

8. For **Duration**, enter the number of hours the maintenance window will run. The value you specify determines the specific end time for the maintenance window based on the time it begins. No maintenance window tasks are permitted to start after the resulting endtime minus the number of hours you specify for **Stop initiating tasks** in the next step.

For example, if the maintenance window starts at 3 PM, the duration is three hours, and the **Stop initiating tasks** value is one hour, no maintenance window tasks can start after 5 PM.

9. For **Stop initiating tasks**, enter the number of hours before the end of the maintenance window that the system should stop scheduling new tasks to run.
10. (Optional) For **Window start date**, specify a date and time, in ISO-8601 Extended format, for when you want the maintenance window to become active. This allows you to delay activation of the maintenance window until the specified future date.
11. (Optional) For **Window end date**, specify a date and time, in ISO-8601 Extended format, for when you want the maintenance window to become inactive. This allows you to set a date and time in the future after which the maintenance window no longer runs.
12. (Optional) For **Schedule timezone**, specify the time zone to base scheduled maintenance window executions on, in Internet Assigned Numbers Authority (IANA) format. For example: "America/Los\_Angeles", "etc/UTC", or "Asia/Seoul".

For more information about valid formats, see the [Time Zone Database](#) on the IANA website.

13. (Optional) In the **Manage tags** area, apply one or more tag key name/value pairs to the maintenance window.

Tags are optional metadata that you assign to a resource. Tags allow you to categorize a resource in different ways, such as by purpose, owner, or environment. For example, you might

want to tag this maintenance window to identify the type of tasks it runs. In this case, you could specify the following key name/value pair:

- Key=TaskType, Value=Patching

14. Choose **Create maintenance window**.

15. In the maintenance windows list, choose the maintenance window you just created, and then choose **Actions, Register targets**.

16. (Optional) In the **Maintenance window target details** section, provide a name, a description, and owner information (your name or alias) for this target.

17. For **Target selection**, choose **Specify instance tags**.

18. For **Specify instance tags**, enter a tag key and a tag value to identify the nodes to register with the maintenance window, and then choose **Add**.

19. Choose **Register target**. The system creates a maintenance window target.

20. In the details page of the maintenance window you created, choose **Actions, Register Run command task**.

21. (Optional) For **Maintenance window task details**, provide a name and description for this task.

22. For **Command document**, choose `AWS-RunPatchBaseline`.

23. For **Task priority**, choose a priority. Zero (0) is the highest priority.

24. For **Targets**, under **Target by**, choose the maintenance window target you created earlier in this procedure.

25. For **Rate control**:

- For **Concurrency**, specify either a number or a percentage of managed nodes on which to run the command at the same time.

 **Note**

If you selected targets by specifying tags applied to managed nodes or by specifying AWS resource groups, and you aren't certain how many managed nodes are targeted, then restrict the number of targets that can run the document at the same time by specifying a percentage.

- For **Error threshold**, specify when to stop running the command on other managed nodes after it fails on either a number or a percentage of nodes. For example, if you specify three

errors, then Systems Manager stops sending the command when the fourth error is received. Managed nodes still processing the command might also send errors.

26. (Optional) For **IAM service role**, choose a role to provide permissions for Systems Manager to assume when running a maintenance window task.

If you don't specify a service role ARN, Systems Manager uses a service-linked role in your account. If no appropriate service-linked role for Systems Manager exists in your account, it's created when the task is registered successfully.

**Note**

For an improved security posture, we strongly recommend creating a custom policy and custom service role for running your maintenance window tasks. The policy can be crafted to provide only the permissions needed for your particular maintenance window tasks. For more information, see [Setting up Maintenance Windows](#).

27. (Optional) For **Output options**, to save the command output to a file, select the **Enable writing output to S3** box. Enter the bucket and prefix (folder) names in the boxes.

**Note**

The S3 permissions that grant the ability to write the data to an S3 bucket are those of the instance profile assigned to the managed node, not those of the IAM user performing this task. For more information, see [Configure instance permissions required for Systems Manager](#) or [Create an IAM service role for a hybrid environment](#). In addition, if the specified S3 bucket is in a different AWS account, verify that the instance profile or IAM service role associated with the managed node has the necessary permissions to write to that bucket.

To stream the output to an Amazon CloudWatch Logs log group, select the **CloudWatch output** box. Enter the log group name in the box.

28. In the **SNS notifications** section, if you want notifications sent about the status of the command execution, select the **Enable SNS notifications** check box.

For more information about configuring Amazon SNS notifications for Run Command, see [Monitoring Systems Manager status changes using Amazon SNS notifications](#).

## 29. For **Parameters**:

- For **Operation**, choose **Scan** to scan for missing patches, or choose **Install** to scan for and install missing patches.
- You don't need to enter anything in the **Snapshot Id** field. This system automatically generates and provides this parameter.
- You don't need to enter anything in the **Install Override List** field unless you want Patch Manager to use a different patch set than is specified for the patch baseline. For information, see [Parameter name: InstallOverrideList](#).
- For **RebootOption**, specify whether you want nodes to reboot if patches are installed during the `Install` operation, or if Patch Manager detects other patches that were installed since the last node reboot. For information, see [Parameter name: RebootOption](#).
- (Optional) For **Comment**, enter a tracking note or reminder about this command.
- For **Timeout (seconds)**, enter the number of seconds the system should wait for the operation to finish before it is considered unsuccessful.

## 30. Choose **Register Run command task**.

After the maintenance window task is complete, you can view patch compliance details in the Systems Manager console in the [Fleet Manager](#) capability.

You can also view compliance information in the [Patch Manager](#) capability, on the **Compliance reporting** tab.

You can also use the [DescribePatchGroupState](#) and [DescribeInstancePatchStatesForPatchGroup](#) APIs to view compliance details. For information about patch compliance data, see [About patch compliance](#).

## Patching schedules using maintenance windows

After you configure a patch baseline (and optionally a patch group), you can apply patches to your node by using a maintenance window. A maintenance window can reduce the impact on server availability by letting you specify a time to perform the patching process that doesn't interrupt business operations. A maintenance window works like this:

1. Create a maintenance window with a schedule for your patching operations.
2. Choose the targets for the maintenance window by specifying the `Patch Group` or `PatchGroup` tag for the tag name, and any value for which you have defined Amazon Elastic

Compute Cloud (Amazon EC2) tags, for example, "web servers" or "US-EAST-PROD. (You must use PatchGroup, without a space, if you have [allowed tags in EC2 instance metadata](#).)

3. Create a new maintenance window task, and specify the `AWS-RunPatchBaseline` document.

When you configure the task, you can choose to either scan nodes or scan and install patches on the nodes. If you choose to scan nodes, Patch Manager, a capability of AWS Systems Manager, scans each node and generates a list of missing patches for you to review.

If you choose to scan and install patches, Patch Manager scans each node and compares the list of installed patches against the list of approved patches in the baseline. Patch Manager identifies missing patches, and then downloads and installs all missing and approved patches.

If you want to perform a one-time scan or install to fix an issue, you can use Run Command to call the `AWS-RunPatchBaseline` document directly.

### Important

After installing patches, Systems Manager reboots each node. The reboot is required to make sure that patches are installed correctly and to ensure that the system didn't leave the node in a potentially bad state. (Exception: If the `RebootOption` parameter is set to `NoReboot` in the `AWS-RunPatchBaseline` document, the managed node isn't rebooted after Patch Manager runs. For more information, see [Parameter name: RebootOption](#).)

## Using pseudo parameters when registering maintenance window tasks

When you register a task in Maintenance Windows, a capability of AWS Systems Manager, you specify the parameters that are unique to each of the four task types. (In CLI commands, these are provided using the `--task-invocation-parameters` option.)

You can also reference certain values using *pseudo parameter* syntax, such as `{{RESOURCE_ID}}`, `{{TARGET_TYPE}}`, and `{{WINDOW_TARGET_ID}}`. When the maintenance window task runs, it passes the correct values instead of the pseudo parameter placeholders. The full list of pseudo parameters you can use is provided later in this topic in [Supported pseudo parameters](#).

### Important

For the target type `RESOURCE_GROUP`, depending on the ID format needed for the task, you can choose between using `{{TARGET_ID}}` and `{{RESOURCE_ID}}` to reference

the resource when your task runs. `{{TARGET_ID}}` returns the full ARN of the resource. `{{RESOURCE_ID}}` returns only a shorter name or ID of the resource, as shown in these examples.

- `{{TARGET_ID}}` format: `arn:aws:ec2:us-east-1:123456789012:instance/i-02573cafcfEXAMPLE`
- `{{RESOURCE_ID}}` format: `i-02573cafcfEXAMPLE`

For target type `INSTANCE`, both the `{{TARGET_ID}}` and `{{RESOURCE_ID}}` parameters yield the instance ID only. For more information, see [Supported pseudo parameters](#). `{{TARGET_ID}}` and `{{RESOURCE_ID}}` can be used to pass IDs of AWS resources only to Automation, Lambda, and Step Functions tasks. These two pseudo parameters can't be used with Run Command tasks.

## Pseudo parameter examples

Suppose that your payload for an AWS Lambda task needs to reference an instance by its ID.

Whether you're using an `INSTANCE` or a `RESOURCE_GROUP` maintenance window target, this can be achieved by using the `{{RESOURCE_ID}}` pseudo parameter. For example:

```
"TaskArn": "arn:aws:lambda:us-east-2:111122223333:function:SSMTestFunction",
  "TaskType": "LAMBDA",
  "TaskInvocationParameters": {
    "Lambda": {
      "ClientContext": "ew0KICAi--truncated--0KIEXAMPLE",
      "Payload": "{ \"instanceId\": \"{{RESOURCE_ID}}\" }",
      "Qualifier": "$LATEST"
    }
  }
}
```

If your Lambda task is intended to run against another supported target type in addition to Amazon Elastic Compute Cloud (Amazon EC2) instances, such as an Amazon DynamoDB table, the same syntax can be used, and `{{RESOURCE_ID}}` yields the name of the table only. However, if you require the full ARN of the table, use `{{TARGET_ID}}`, as shown in the following example.

```
"TaskArn": "arn:aws:lambda:us-east-2:111122223333:function:SSMTestFunction",
  "TaskType": "LAMBDA",
```

```

"TaskInvocationParameters": {
  "Lambda": {
    "ClientContext": "ew0KICAi--truncated--0KIEXAMPLE",
    "Payload": "{ \"tableArn\": \"{{TARGET_ID}}\" }",
    "Qualifier": "$LATEST"
  }
}

```

The same syntax works for targeting instances or other resource types. When multiple resource types have been added to a resource group, the task runs against each of the appropriate resources.

### Important

Not all resource types that might be included in a resource group yield a value for the `{{RESOURCE_ID}}` parameter. For a list of supported resource types, see [Supported pseudo parameters](#).

As another example, to run an Automation task that stops your EC2 instances, you specify the `AWS-StopEC2Instance` Systems Manager document (SSM document) as the `TaskArn` value and use the `{{RESOURCE_ID}}` pseudo parameter:

```

"TaskArn": "AWS-StopEC2Instance",
"TaskType": "AUTOMATION"
"TaskInvocationParameters": {
  "Automation": {
    "DocumentVersion": "1",
    "Parameters": {
      "instanceId": [
        "{{RESOURCE_ID}}"
      ]
    }
  }
}

```

To run an Automation task that copies a snapshot of an Amazon Elastic Block Store (Amazon EBS) volume, you specify the `AWS-CopySnapshot` SSM document as the `TaskArn` value and use the `{{RESOURCE_ID}}` pseudo parameter.

```

"TaskArn": "AWS-CopySnapshot",

```

```
"TaskType": "AUTOMATION"
"TaskInvocationParameters": {
  "Automation": {
    "DocumentVersion": "1",
    "Parameters": {
      "SourceRegion": "us-east-2",
      "targetType": "RESOURCE_GROUP",
      "SnapshotId": [
        "{{RESOURCE_ID}}"
      ]
    }
  }
}
```

## Supported pseudo parameters

The following list describes the pseudo parameters that you can specify using the `{{PSEUDO_PARAMETER}}` syntax in the `--task-invocation-parameters` option.

- **WINDOW\_ID**: The ID of the target maintenance window.
- **WINDOW\_TASK\_ID**: The ID of the window task that is running.
- **WINDOW\_TARGET\_ID**: The ID of the window target that includes the target (target ID).
- **WINDOW\_EXECUTION\_ID**: The ID of the current window execution.
- **TASK\_EXECUTION\_ID**: The ID of the current task execution.
- **INVOCATION\_ID**: The ID of the current invocation.
- **TARGET\_TYPE**: The type of target. Supported types include `RESOURCE_GROUP` and `INSTANCE`.
- **TARGET\_ID**:

If the target type you specify is `INSTANCE`, the `TARGET_ID` pseudo parameter is replaced by the ID of the instance. For example, `i-078a280217EXAMPLE`.

If the target type you specify is `RESOURCE_GROUP`, the value referenced for the task execution is the full ARN of the resource. For example: `arn:aws:ec2:us-east-1:123456789012:instance/i-078a280217EXAMPLE`. The following table provides sample `TARGET_ID` values for particular resource types in a resource group.

**Note**

TARGET\_ID isn't supported for Run Command tasks.

| Resource type           | Example TARGET_ID   |
|-------------------------|---|
| AWS::CloudWatch::Alarm  | arn:aws:cloudwatch:us-east-1:123456789012:alarm:MyCloudWatchAlarm i-078a280217EXAMPLE |
| AWS::EC2::Instance      | arn:aws:ec2:us-east-1:123456789012:instance/ i-078a280217EXAMPLE                      |
| AWS::EC2::Image         | arn:aws:ec2:us-east-1:123456789012:image/ami-02250b3732EXAMPLE                        |
| AWS::EC2::SecurityGroup | arn:aws:ec2:us-east-1:123456789012:security-group/sg-cEXAMPLE                         |
| AWS::EC2::Snapshot      | arn:aws:ec2:us-east-1:123456789012:snapshot/snap-03866bf003EXAMPLE                    |

| Resource type             | Example TARGET_ID  |
|---------------------------|--|
| AWS::EC2::Volume          | arn:aws:ec2:us-east-1:123456789012:volume/vol-0912e04d78EXAMPLE                            |
| AWS::DynamoDB::Table      | arn:aws:dynamodb:us-east-1:123456789012:table/MyTable                                      |
| AWS::RDS::DBCluster       | arn:aws:rds:us-east-2:123456789012:cluster:My-Cluster                                      |
| AWS::RDS::DBInstance      | arn:aws:rds:us-east-1:123456789012:db:My-SQL-Instance                                      |
| AWS::S3::Bucket           | arn:aws:s3:::amzn-s3-demo-bucket   |
| AWS::SSM::ManagedInstance | arn:aws:ssm:us-east-1:123456789012:managed-instance/managed-instance/mi-0feadcfc2d9EXAMPLE |

- **RESOURCE\_ID:** The short ID of a resource type contained in a resource group. The following table provides sample RESOURCE\_ID values for particular resource types in a resource group.

 **Note**

RESOURCE\_ID isn't supported for Run Command tasks.

| Resource type             | Example RESOURCE_ID    |
|---------------------------|------------------------|
| AWS::CloudWatch::Alarm    | MyCloudWatchAlarm      |
| AWS::EC2::Instance        | i-078a280217EXAMPLE    |
| AWS::EC2::Image           | ami-02250b3732EXAMPLE  |
| AWS::EC2::SecurityGroup   | sg-cEXAMPLE            |
| AWS::EC2::Snapshot        | snap-03866bf003EXAMPLE |
| AWS::EC2::Volume          | vol-0912e04d78EXAMPLE  |
| AWS::DynamoDB::Table      | MyTable                |
| AWS::RDS::DBCluster       | My-Cluster             |
| AWS::RDS::DBInstance      | My-SQL-Instance        |
| AWS::S3::Bucket           | amzn-s3-demo-bucket    |
| AWS::SSM::ManagedInstance | mi-0feadc2d9EXAMPLE    |

**Note**

If the AWS resource group you specify includes resource types that don't yield a RESOURCE\_ID value, and aren't listed in the preceding table, then the RESOURCE\_ID parameter isn't populated. An execution invocation will still occur for that resource. In

these cases, use the `TARGET_ID` pseudo parameter instead, which will be replaced with the full ARN of the resource.

## Maintenance window scheduling and active period options

When you create a maintenance window, you must specify how often the maintenance window runs by using a [Cron or rate expression](#). Optionally, you can specify a date range during which the maintenance window can run on its regular schedule and a time zone on which to base that regular schedule.

Be aware, however, that the time zone option and the start date and end date options don't influence each other. Any start date and end date times that you specify (with or without an offset for your time zone) determine only the *valid period* during which the maintenance window can run on its schedule. A time zone option determines the international time zone that the maintenance window schedule is based on *during* its valid period.

### Note

You specify start and end dates in ISO-8601 timestamp format. For example:

```
2021-04-07T14:29:00-08:00
```

You specify time zones in Internet Assigned Numbers Authority (IANA) format. For example: America/Chicago, Europe/Berlin or Asia/Tokyo

## Examples

- [Example 1: Specify a maintenance window start date](#)
- [Example 2: Specify a maintenance window start date and end date](#)
- [Example 3: Create a maintenance window that runs only once](#)
- [Example 4: Specify the number of schedule offset days for a maintenance window](#)

### Example 1: Specify a maintenance window start date

Say that you use the AWS Command Line Interface (AWS CLI) to create a maintenance window with the following options:

- `--start-date 2021-01-01T00:00:00-08:00`

- `--schedule-timezone "America/Los_Angeles"`
- `--schedule "cron(0 09 ? * WED *)"`

For example:

## Linux & macOS

```
aws ssm create-maintenance-window \
  --name "My-LAX-Maintenance-Window" \
  --allow-unassociated-targets \
  --duration 3 \
  --cutoff 1 \
  --start-date 2021-01-01T00:00:00-08:00 \
  --schedule-timezone "America/Los_Angeles" \
  --schedule "cron(0 09 ? * WED *)"
```

## Windows

```
aws ssm create-maintenance-window ^
  --name "My-LAX-Maintenance-Window" ^
  --allow-unassociated-targets ^
  --duration 3 ^
  --cutoff 1 ^
  --start-date 2021-01-01T00:00:00-08:00 ^
  --schedule-timezone "America/Los_Angeles" ^
  --schedule "cron(0 09 ? * WED *)"
```

This means that the first run of the maintenance window won't occur until *after* its specified start date and time, which is at 12:00 AM US Pacific Time on Friday, January 1, 2021. (This time zone is eight hours behind UTC time.) In this case, the start date and time of the window period don't represent when the maintenance windows first runs. Taken together, the `--schedule-timezone` and `--schedule` values mean that the maintenance window runs at 9 AM every Wednesday in the US Pacific Time Zone (represented by "America/Los Angeles" in IANA format). The first execution in the allowed period will be on Wednesday, January 4, 2021, at 9 AM US Pacific Time.

### Example 2: Specify a maintenance window start date and end date

Suppose that next you create a maintenance window with these options:

- `--start-date 2019-01-01T00:03:15+09:00`

- `--end-date 2019-06-30T00:06:15+09:00`
- `--schedule-timezone "Asia/Tokyo"`
- `--schedule "rate(7 days)"`

For example:

## Linux & macOS

```
aws ssm create-maintenance-window \  
  --name "My-NRT-Maintenance-Window" \  
  --allow-unassociated-targets \  
  --duration 3 \  
  --cutoff 1 \  
  --start-date 2019-01-01T00:03:15+09:00 \  
  --end-date 2019-06-30T00:06:15+09:00 \  
  --schedule-timezone "Asia/Tokyo" \  
  --schedule "rate(7 days)"
```

## Windows

```
aws ssm create-maintenance-window ^  
  --name "My-NRT-Maintenance-Window" ^  
  --allow-unassociated-targets ^  
  --duration 3 ^  
  --cutoff 1 ^  
  --start-date 2019-01-01T00:03:15+09:00 ^  
  --end-date 2019-06-30T00:06:15+09:00 ^  
  --schedule-timezone "Asia/Tokyo" ^  
  --schedule "rate(7 days)"
```

The allowed period for this maintenance window begins at 3:15 AM Japan Standard Time on January 1, 2019. The valid period for this maintenance window ends at 6:15 AM Japan Standard Time on Sunday, June 30, 2019. (This time zone is nine hours ahead of UTC time.) Taken together, the `--schedule-timezone` and `--schedule` values mean that the maintenance window runs at 3:15 AM every Tuesday in the Japan Standard Time Zone (represented by "Asia/Tokyo" in IANA format). This is because the maintenance window runs every seven days, and it becomes active at 3:15 AM on Tuesday, January 1. The last execution is at 3:15 AM Japan Standard Time on Tuesday, June 25, 2019. This is the last Tuesday before the allowed maintenance window period ends five days later.

### Example 3: Create a maintenance window that runs only once

Now you create a maintenance window with this option:

- `--schedule "at(2020-07-07T15:55:00)"`

For example:

#### Linux & macOS

```
aws ssm create-maintenance-window \  
  --name "My-One-Time-Maintenance-Window" \  
  --schedule "at(2020-07-07T15:55:00)" \  
  --duration 5 \  
  --cutoff 2 \  
  --allow-unassociated-targets
```

#### Windows

```
aws ssm create-maintenance-window ^  
  --name "My-One-Time-Maintenance-Window" ^  
  --schedule "at(2020-07-07T15:55:00)" ^  
  --duration 5 ^  
  --cutoff 2 ^  
  --allow-unassociated-targets
```

This maintenance window runs just once, at 3:55 PM UTC time on July 7, 2020. The maintenance window is allowed to run up to five hours, as needed, but new tasks are prevented from starting two hours before the end of the maintenance window period.

### Example 4: Specify the number of schedule offset days for a maintenance window

Now you create a maintenance window with this option:

```
--schedule-offset 2
```

For example:

#### Linux & macOS

```
aws ssm create-maintenance-window \  
  --schedule-offset 2
```

```
--name "My-Cron-Offset-Maintenance-Window" \  
--schedule "cron(0 30 23 ? * TUE#3 *)" \  
--duration 4 \  
--cutoff 1 \  
--schedule-offset 2 \  
--allow-unassociated-targets
```

## Windows

```
aws ssm create-maintenance-window ^  
  --name "My-Cron-Offset-Maintenance-Window" ^  
  --schedule "cron(0 30 23 ? * TUE#3 *)" ^  
  --duration 4 ^  
  --cutoff 1 ^  
  --schedule-offset 2 ^  
  --allow-unassociated-targets
```

A schedule offset is the number of days to wait after the date and time specified by a CRON expression before running the maintenance window.

In the preceding example, the CRON expression schedules a maintenance window to run the third Tuesday of every month at 11:30 PM:

```
--schedule "cron(0 30 23 ? * TUE#3 *)
```

However, including `--schedule-offset 2` means that the maintenance window won't run until 11:30 PM two days *after* the third Tuesday of each month.

Schedule offsets are supported for CRON expressions only.

## Registering maintenance window tasks without targets

For each maintenance window you create, you can specify one or more tasks to perform when the maintenance window runs. In most cases, you must specify the resources, or targets, that the task is to run on. In some cases, however, you don't need to specify targets explicitly in the task.

One or more targets must be specified for maintenance window Systems Manager Run Command-type tasks. Depending on the nature of the task, targets are optional for other maintenance window task types (Systems Manager Automation, AWS Lambda, and AWS Step Functions).

For Lambda and Step Functions task types, whether a target is required depends on the content of the function or state machine you have created.

In many cases, you don't need to explicitly specify a target for an automation task. For example, say that you're creating an Automation-type task to update an Amazon Machine Image (AMI) for Linux using the `AWS-UpdateLinuxAmi` runbook. When the task runs, the AMI is updated with the latest available Linux distribution packages and Amazon software. New instances created from the AMI already have these updates installed. Because the ID of the AMI to be updated is specified in the input parameters for the runbook, there is no need to specify a target again in the maintenance window task.

Similarly, suppose you're using the AWS Command Line Interface (AWS CLI) to register a maintenance window Automation task that uses the `AWS-RestartEC2Instance` runbook. Because the node to restart is specified in the `--task-invocation-parameters` argument, you don't need to also specify a `--targets` option.

### Note

For maintenance window tasks without a target specified, you can't supply values for `--max-errors` and `--max-concurrency`. Instead, the system inserts a placeholder value of 1, which might be reported in the response to commands such as [describe-maintenance-window-tasks](#) and [get-maintenance-window-task](#). These values don't affect the running of your task and can be ignored.

The following example demonstrates omitting the `--targets`, `--max-errors`, and `--max-concurrency` options for a targetless maintenance window task.

## Linux & macOS

```
aws ssm register-task-with-maintenance-window \
  --window-id "mw-ab12cd34eEXAMPLE" \
  --service-role-arn "arn:aws:iam::123456789012:role/
MaintenanceWindowAndAutomationRole" \
  --task-type "AUTOMATION" \
  --name "RestartInstanceWithoutTarget" \
  --task-arn "AWS-RestartEC2Instance" \
  --task-invocation-parameters "{\"Automation\":{\"Parameters\":{\"InstanceId\":
[\"i-02573cafcfEXAMPLE\"]}}}" \
  --priority 10
```

## Windows

```
aws ssm register-task-with-maintenance-window ^
  --window-id "mw-ab12cd34eEXAMPLE" ^
  --service-role-arn "arn:aws:iam::123456789012:role/
MaintenanceWindowAndAutomationRole" ^
  --task-type "AUTOMATION" ^
  --name "RestartInstanceWithoutTarget" ^
  --task-arn "AWS-RestartEC2Instance" ^
  --task-invocation-parameters "{\"Automation\":{\"Parameters\":{\"InstanceId\":
[\"i-02573cafcfEXAMPLE\"]}}}" ^
  --priority 10
```

### Note

For maintenance window tasks registered before December 23, 2020: If you specified targets for the task and one is no longer required, you can update that task to remove the targets using the Systems Manager console or the [update-maintenance-window-task](#) AWS CLI command.

## More info

- [Error messages: "Maintenance window tasks without targets don't support MaxConcurrency values" and "Maintenance window tasks without targets don't support MaxErrors values"](#)

## Troubleshooting maintenance windows

Use the following information to help you troubleshoot problems with maintenance windows.

### Topics

- [Edit task error: On the page for editing a maintenance window task, the IAM role list returns an error message: "We couldn't find the IAM maintenance window role specified for this task. It might have been deleted, or it might not have been created yet."](#)
- [Not all maintenance window targets are updated](#)
- [Task fails with task invocation status: "The provided role does not contain the correct SSM permissions."](#)
- [Task fails with error message: "Step fails when it is validating and resolving the step inputs"](#)
- [Error messages: "Maintenance window tasks without targets don't support MaxConcurrency values" and "Maintenance window tasks without targets don't support MaxErrors values"](#)

**Edit task error:** On the page for editing a maintenance window task, the IAM role list returns an error message: "We couldn't find the IAM maintenance window role specified for this task. It might have been deleted, or it might not have been created yet."

**Problem 1:** The AWS Identity and Access Management (IAM) maintenance window role you originally specified was deleted after you created the task.

**Possible fix:** 1) Select a different IAM maintenance window role, if one exists in your account, or create a new one and select it for the task.

**Problem 2:** If the task was created using the AWS Command Line Interface (AWS CLI), AWS Tools for Windows PowerShell, or an AWS SDK, a non-existent IAM maintenance window role name could have been specified. For example, the IAM maintenance window role could have been deleted before you created the task, or the role name could have been typed incorrectly, such as **myrole** instead of **my-role**.

**Possible fix:** Select the correct name of the IAM maintenance window role you want to use, or create a new one to specify for the task.

### Not all maintenance window targets are updated

**Problem:** You notice that maintenance window tasks didn't run on all the resources targeted by your maintenance window. For example, in the maintenance window run results, the task for that resource is marked as failed or timed out.

**Solution:** The most common reasons for a maintenance window task not running on a target resource involve connectivity and availability. For example:

- Systems Manager lost connection to the resource before or during the maintenance window operation.
- The resource was offline or stopped during the maintenance window operation.

You can wait for the next scheduled maintenance window time to run tasks on the resources. You can manually run the maintenance window tasks on the resources that weren't available or were offline.

**Task fails with task invocation status: "The provided role does not contain the correct SSM permissions."**

**Problem:** You have specified a maintenance window service role for a task, but the task fails to run successfully and the task invocation status reports that "The provided role does not contain the correct SSM permissions."

- **Solution:** In [Task 1: Create a custom policy for your maintenance window service role using the console](#), we provide a basic policy you can attach to your [custom maintenance window service role](#). The policy includes the permissions needed for many task scenarios. However, due to the wide variety of tasks you can run, you might need to provide additional permissions in the policy for your maintenance window role.

For example, some Automation actions work with AWS CloudFormation stacks. Therefore, you might need to add the additional permissions `cloudformation:CreateStack`, `cloudformation:DescribeStacks`, and `cloudformation>DeleteStack` to the policy for your maintenance window service role.

For another example, the Automation runbook `AWS-CopySnapshot` requires permissions to create an Amazon Elastic Block Store (Amazon EBS) snapshot. Therefore, you might need to add the permission `ec2:CreateSnapshot`.

For information about the role permissions needed by an AWS managed Automation runbook, see the runbook descriptions in the [AWS Systems Manager Automation runbook reference](#).

For information about the role permissions needed by an AWS managed SSM document, review the content of the document in the [Documents](#) section Systems Manager console.

For information about the role permissions needed for Step Functions tasks, Lambda tasks, and custom Automation runbooks and SSM documents, verify permission requirements with the author of those resources.

### Task fails with error message: "Step fails when it is validating and resolving the step inputs"

**Problem:** An Automation runbook or Systems Manager Command document you're using in a task requires that you specify inputs such as InstanceId or SnapshotId, but a value isn't supplied or isn't supplied correctly.

- **Solution 1:** If your task is targeting a single resource, such as a single node or single snapshot, enter its ID in the input parameters for the task.
- **Solution 2:** If your task is targeting multiple resources, such as creating images from multiple nodes when you use the runbook `AWS-CreateImage`, you can use one of the pseudo parameters supported for maintenance window tasks in the input parameters to represent node IDs in the command.

The following commands register a Systems Manager Automation task with a maintenance window using the AWS CLI. The `--targets` value indicates a maintenance window target ID. Also, even though the `--targets` parameter specifies a window target ID, parameters of the Automation runbook require that a node ID be provided. In this case, the command uses the pseudo parameter `{{RESOURCE_ID}}` as the InstanceId value.

#### AWS CLI command:

Linux & macOS

The following example command restarts Amazon Elastic Compute Cloud (Amazon EC2) instances that belong to the maintenance window target group with the ID `e32eeeb2-646c-4f4b-8ed1-205fbEXAMPLE`.

```
aws ssm register-task-with-maintenance-window \  
  --window-id "mw-0c50858d01EXAMPLE" \  
  --targets Key=WindowTargetIds,Values=e32eeeb2-646c-4f4b-8ed1-205fbEXAMPLE \  
  --task-arn "AWS-RestartEC2Instance" \  
  --service-role-arn arn:aws:iam::123456789012:role/  
MyMaintenanceWindowServiceRole \  
  --task-type AUTOMATION \  

```

```

--task-invocation-parameters
"Automation={DocumentVersion=5,Parameters={InstanceId='{{RESOURCE_ID}}'}}" \
--priority 0 --max-concurrency 10 --max-errors 5 --name "My-Restart-EC2-
Instances-Automation-Task" \
--description "Automation task to restart EC2 instances"

```

## Windows

```

aws ssm register-task-with-maintenance-window ^
--window-id "mw-0c50858d01EXAMPLE" ^
--targets Key=WindowTargetIds,Values=e32eecb2-646c-4f4b-8ed1-205fbEXAMPLE ^
--task-arn "AWS-RestartEC2Instance" ^
--service-role-arn arn:aws:iam::123456789012:role/
MyMaintenanceWindowServiceRole ^
--task-type AUTOMATION ^
--task-invocation-parameters
"Automation={DocumentVersion=5,Parameters={InstanceId='{{RESOURCE_ID}}'}}" ^
--priority 0 --max-concurrency 10 --max-errors 5 --name "My-Restart-EC2-
Instances-Automation-Task" ^
--description "Automation task to restart EC2 instances"

```

For more information about working with pseudo parameters for maintenance window tasks, see [Using pseudo parameters when registering maintenance window tasks](#) and [Task registration examples](#).

**Error messages: "Maintenance window tasks without targets don't support MaxConcurrency values" and "Maintenance window tasks without targets don't support MaxErrors values"**

**Problem:** When you register a Run Command-type task, you must specify at least one target for the task to run on. For other task types (Automation, AWS Lambda, and AWS Step Functions), depending on the nature of the task, targets are optional. The options `MaxConcurrency` (the number of resources to run a task on at the same time) and `MaxErrors` (the number of failures to run the task on target resources before the task fails) aren't required or supported for maintenance window tasks that don't specify targets. The system generates these error messages if values are specified for either of these options when no task target is specified.

**Solution:** If you receive either of these errors, remove the values for concurrency and error threshold before continuing to register or update the maintenance window task.

For more information about running tasks that don't specify targets, see [Registering maintenance window tasks without targets](#) in the *AWS Systems Manager User Guide*.

## AWS Systems Manager Node tools

AWS Systems Manager provides the following capabilities for accessing, managing, and configuring your *managed nodes*. A managed node is any machine configured for use with Systems Manager in a [hybrid and multicloud](#) environment.

### Topics

- [AWS Systems Manager Fleet Manager](#)
- [AWS Systems Manager Compliance](#)
- [AWS Systems Manager Inventory](#)
- [AWS Systems Manager Hybrid Activations](#)
- [AWS Systems Manager Session Manager](#)
- [AWS Systems Manager Run Command](#)
- [AWS Systems Manager State Manager](#)
- [AWS Systems Manager Patch Manager](#)
- [AWS Systems Manager Distributor](#)

## AWS Systems Manager Fleet Manager

Fleet Manager, a capability of AWS Systems Manager, is a unified user interface (UI) experience that helps you remotely manage your nodes running on AWS or on premises. With Fleet Manager, you can view the health and performance status of your entire server fleet from one console. You can also gather data from individual nodes to perform common troubleshooting and management tasks from the console. This includes connecting to Windows instances using the Remote Desktop Protocol (RDP), viewing folder and file contents, Windows registry management, operating system user management, and more. To get started with Fleet Manager, open the [Systems Manager console](#). In the navigation pane, choose **Fleet Manager**.

### Who should use Fleet Manager?

Any AWS customer who wants a centralized way to manage their node fleet should use Fleet Manager.

## How can Fleet Manager benefit my organization?

Fleet Manager offers these benefits:

- Perform a variety of common systems administration tasks without having to manually connect to your managed nodes.
- Manage nodes running on multiple platforms from a single unified console.
- Manage nodes running different operating systems from a single unified console.
- Improve the efficiency of your systems administration.

## What are the features of Fleet Manager?

Key features of Fleet Manager include the following:

- **Access the Red Hat Knowledgebase Portal**

Access binaries, knowledge-shares, and discussion forums on the Red Hat Knowledgebase Portal through your Red Hat Enterprise Linux (RHEL) instances.

- **Managed node status**

View which managed instances are running and which are stopped. For more information about stopped instances, see [Stop and start your instance](#) in the *Amazon EC2 User Guide*. For AWS IoT Greengrass core devices, you can view which are online, offline, or show a status of Connection lost.

 **Note**

If you stopped your managed instance before July 12, 2021, it won't display the stopped marker. To show the marker, start and stop the instance.

- **View instance information**

View information about the folder and file data stored on the volumes attached to your managed instances, performance data about your instances in real-time, and log data stored on your instances.

- **View edge device information**

View the AWS IoT Greengrass Thing name for the device, SSM Agent ping status and version, and more.

- **Manage accounts and registry**

Manage operating system (OS) user accounts on your instances and registry on your Windows instances.

- **Control access to features**

Control access to Fleet Manager features using AWS Identity and Access Management (IAM) policies. With these policies, you can control which individual users or groups in your organization can use various Fleet Manager features, and which managed nodes they can manage.

## Topics

- [Setting up Fleet Manager](#)
- [Working with managed nodes](#)
- [Managing EC2 instances automatically with Default Host Management Configuration](#)
- [Connecting to a Windows Server managed instance using Remote Desktop](#)
- [Managing Amazon EBS volumes on managed instances](#)
- [Accessing the Red Hat Knowledge base portal](#)
- [Troubleshooting managed node availability](#)

## Setting up Fleet Manager

Before users in your AWS account can use Fleet Manager, a capability of AWS Systems Manager, to monitor and manage your managed nodes, they must be granted the necessary permissions. In addition, any Amazon Elastic Compute Cloud (Amazon EC2) instances; AWS IoT Greengrass core devices; and on-premises servers, edge devices, and virtual machines (VMs) to be monitored and managed using Fleet Manager must be Systems Manager *managed nodes*. A managed node is any machine configured for use with Systems Manager in [hybrid and multicloud](#) environments.

This means your nodes must meet certain prerequisites and be configured with the AWS Systems Manager Agent (SSM Agent).

Depending on the machine type, refer to one of the following topics to ensure your machines meet the requirements for managed nodes.

- Amazon EC2 instances: [Managing EC2 instances with Systems Manager](#)

### Tip

You can also use Quick Setup, a capability of AWS Systems Manager, to help you quickly configure your Amazon EC2 instances as managed instances in an individual account. If your business or organization uses AWS Organizations, you can also configure instances across multiple organizational units (OUs) and AWS Regions. For more information about using Quick Setup to configure managed instances, see [Set up Amazon EC2 host management using Quick Setup](#).

- On-premises and other server types in the cloud: [Managing nodes in hybrid and multicloud environments with Systems Manager](#)
- AWS IoT Greengrass (edge) devices: [Managing edge devices with Systems Manager](#)

## Sample policies

- [Controlling access to Fleet Manager](#)

## Controlling access to Fleet Manager

To use Fleet Manager, a capability of AWS Systems Manager, your AWS Identity and Access Management (IAM) user or role must have the required permissions. You can create an IAM policy that provides access to all Fleet Manager features, or modify your policy to grant access to the features you choose. You then grant these permissions to users, or identities, in your account.

### Task 1: Create IAM policies to define access permissions

Follow one of the methods provided in the following topic in the *IAM User Guide* to create an IAM to provide identities (users, roles, or user groups) with access to Fleet Manager:

- [Define custom IAM permissions with customer managed policies](#)

You can use one of the sample policies we provide below, or modify them according to the permissions you want to grant. We provide sample policies for full Fleet Manager access and read-only access.

## Task 2: Attach the IAM policies to users to grant permissions

After you have created the IAM policy or policies that define access permissions to Fleet Manager, use one of the following procedures in the *IAM User Guide* to grant these permissions to identities in your account:

- [Adding IAM identity permissions \(console\)](#)
- [Adding IAM identity permissions \(AWS CLI\)](#)
- [Adding IAM identity permissions \(AWS API\)](#)

### Topics

- [Sample policy for Fleet Manager administrator access](#)
- [Sample policy for Fleet Manager read-only access](#)

### Sample policy for Fleet Manager administrator access

The following policy provides permissions to all Fleet Manager features. This means a user can create and delete local users and groups, modify group membership for any local group, and modify Windows Server registry keys or values. Replace each *example resource placeholder* with your own information.

```

        "arn:aws:ssm:*:*:document/AWSFleetManager-GetWindowsEvents",
        "arn:aws:ssm:*:*:document/AWSFleetManager-GetWindowsRegistryContent"
    ]
},
{
    "Sid": "TerminateSession",
    "Effect": "Allow",
    "Action": [

```

```

        "ssm:TerminateSession"
    ],
    "Resource": "*",
    "Condition": {
        "StringLike": {
            "ssm:resourceTag/aws:ssmmessages:session-id": [
                "${aws:userid}"
            ]
        }
    }
},
{
    "Sid": "KMS",
    "Effect": "Allow",
    "Action": [
        "kms:GenerateDataKey"
    ],
    "Resource": [
        "arn:aws:kms:region:account-id:key/key-ID"
    ]
}
]
}

```

## Working with managed nodes

A *managed node* is any machine configured for AWS Systems Manager. You can configure the following machine types as managed nodes:

- Amazon Elastic Compute Cloud (Amazon EC2) instances
- Servers on your own premises (on-premises servers)
- AWS IoT Greengrass core devices
- AWS IoT and non-AWS edge devices
- Virtual machines (VMs), including VMs in other cloud environments

In the Systems Manager console, any machine prefixed with "mi-" is has been configured as a managed node using a [hybrid activation](#). Edge devices display their AWS IoT Thing name.

**Note**

The only supported feature for macOS instances is viewing the file system.

## About Systems Manager instances tiers

AWS Systems Manager offers a standard-instances tier and an advanced-instances tier. Both support managed nodes in your [hybrid and multicloud](#) environment. The standard-instances tier allows you to register a maximum of 1,000 machines per AWS account per AWS Region. If you need to register more than 1,000 machines in a single account and Region, then use the advanced-instances tier. You can create as many managed nodes as you like in the advanced-instances tier. All managed nodes configured for Systems Manager are priced on a pay-per-use basis. For more information about enabling the advanced instances tier, see [Turning on the advanced-instances tier](#). For more information about pricing, see [AWS Systems Manager Pricing](#).

Note the following additional information about the standard-instances tier and advanced-instances tier:

- Advanced instances also allow you to connect to your non-EC2 nodes in a [hybrid and multicloud](#) environment by using AWS Systems Manager Session Manager. Session Manager provides interactive shell access to your instances. For more information, see [AWS Systems Manager Session Manager](#).
- The standard-instances quota also applies to EC2 instances that use a Systems Manager on-premises activation (which isn't a common scenario).
- To patch applications released by Microsoft on virtual machines (VMs) on-premises instances, activate the advanced-instances tier. There is a charge to use the advanced-instances tier. There is no additional charge to patch applications released by Microsoft on Amazon Elastic Compute Cloud (Amazon EC2) instances. For more information, see [Patching applications released by Microsoft on Windows Server](#).

## Display managed nodes

If you don't see your managed nodes listed in the console, then do the following:

1. Verify that the console is open in the AWS Region where you created your managed nodes. You can switch Regions by using the list in the top, right corner of the console.

2. Verify that the setup steps for your managed nodes meet Systems Manager requirements. For information, see [Setting up managed nodes for AWS Systems Manager](#).
3. For non-EC2 machines, verify that you completed the hybrid activation process. For more information, see [Managing nodes in hybrid and multicloud environments with Systems Manager](#).

Note the following additional information:

- The Fleet Manager console does not display Amazon EC2 nodes that have been terminated.
- Systems Manager requires accurate time references in order to perform operations on your machines. If the date and time aren't set correctly on your managed nodes, the machines might not match the signature date of your API requests. For more information, see [Use cases and best practices](#).
- When you create or edit tags, the system can take up to one hour to display changes in the table filter.
- After the status of a managed node has been `Connection Lost` for at least 30 days, the node might no longer be listed in the Fleet Manager console. To restore it to the list, the issue that caused the lost connection must be resolved. For troubleshooting tips, see [Troubleshooting managed node availability](#).

## Verify Systems Manager support on a managed node

AWS Config provides AWS Managed Rules, which are predefined, customizable rules that AWS Config uses to evaluate whether your AWS resource configurations comply with common best practices. AWS Config Managed Rules include the [ec2-instance-managed-by-systems-manager](#) rule. This rule checks whether the Amazon EC2 instances in your account are managed by Systems Manager. For more information, see [AWS Config Managed Rules](#).

## Increase security posture on managed nodes

For information about increasing your security posture against unauthorized root-level commands on your managed nodes, see [Restricting access to root-level commands through SSM Agent](#).

## Deregister managed nodes

You can deregister managed nodes at any time. For example, if you're managing multiple nodes with the same AWS Identity and Access Management (IAM) role and you notice any kind of malicious behavior, you can deregister any number of machines at any point. For information

about deregistering managed nodes, see [Deregistering managed nodes in a hybrid and multicloud environment](#).

- [Managing OS user accounts and groups on managed nodes using Fleet Manager](#)
- [Managing the Windows registry on managed nodes](#)

## Configuring instance tiers

This topic describes the scenarios when you must activate the advanced-instances tier.

AWS Systems Manager offers a standard-instances tier and an advanced-instances tier for non-EC2 machines in a [hybrid and multicloud](#) environment.

You can register up to 1,000 standard [hybrid-activated nodes](#) per account per AWS Region at no additional cost. However, registering more than 1,000 hybrid nodes requires that you activate the advanced-instances tier. There is a charge to use the advanced-instances tier. For more information, see [AWS Systems Manager Pricing](#).

Even with fewer than 1,000 registered hybrid-activated nodes, two other scenarios require the advanced-instances tier:

- You want to use Session Manager to connect to non-EC2 nodes.
- You want to patch applications (not operating systems) released by Microsoft on non-EC2 nodes.

### Note

There is no charge to patch applications released by Microsoft on Amazon EC2 instances.

## Advanced-instances tier detailed scenarios

The following information provides details on the three scenarios for which you must activate the advanced-instances tier.

### Scenario 1: You want to register more than 1,000 hybrid-activated nodes

Using the standard-instances tier, you can register a maximum of 1,000 non-EC2 nodes in a [hybrid and multicloud](#) environment per AWS Region in a specific account without additional charge. If you need to register more than 1,000 non-EC2 nodes in a Region, you must use the advanced-instances tier. You can then activate as many machines for your hybrid and multicloud environment as you want. Charges for the advanced-instances tier are based on the number of advanced nodes activated as Systems Manager managed nodes and the hours those nodes are running.

All Systems Manager managed nodes that use the activation process described in [Create a hybrid activation to register nodes with Systems Manager](#) are then subject to charge if you exceed 1,000 on-premises nodes in a Region in a specific account .

#### Note

You can also activate existing Amazon Elastic Compute Cloud (Amazon EC2) instances using Systems Manager hybrid activations and work with them as non-EC2 instances, such as for testing. These also qualify as hybrid nodes. This isn't a common scenario.

### Scenario 2: Patching Microsoft-released applications on hybrid-activated nodes

The advanced-instances tier is also required if you want to patch Microsoft-released applications on non-EC2 nodes in a hybrid and multicloud environment. If you activate the advanced-instances tier to patch Microsoft applications on non-EC2 nodes, charges are then incurred for all on-premises nodes, even if you have fewer than 1,000.

There is no additional charge to patch applications released by Microsoft on Amazon Elastic Compute Cloud (Amazon EC2) instances. For more information, see [Patching applications released by Microsoft on Windows Server](#).

### Scenario 3: Connecting to hybrid-activated nodes using Session Manager

Session Manager provides interactive shell access to your instances. To connect to hybrid-activated managed nodes using Session Manager, you must activate the advanced-instances tier. Charges are then incurred for all hybrid-activated nodes, even if you have fewer than 1,000.

#### Summary: When do I need the advanced-instances tier?

Use the following table to review when you must use the advanced-instances tier, and for which scenarios additional charges apply.

| Scenario  | Advanced-instances tier required? | Additional charges apply? |
|---|-----------------------------------|---------------------------|
| The number of hybrid-activated nodes in my Region in a specific account is more than 1,000.   | Yes                               | Yes                       |
| I want to use Patch Manager to patch Microsoft-released applications on any number of hybrid-activated nodes, even less than 1,000.   | Yes                               | Yes                       |
| I want to use Session Manager to connect to any number of hybrid-activated nodes, even less than 1,000.   | Yes                               | Yes                       |
| <ol style="list-style-type: none"> <li>The number of hybrid-activated nodes in a Region in a specific account is 1,000 or less; and</li> <li>I am not patching Microsoft applications on any hybrid-activated nodes; and</li> </ol> | No                                | No                        |

| Scenario  | Advanced-instances tier required? | Additional charges apply? |
|---|-----------------------------------|---------------------------|
| 3. I am not connecting to any hybrid-activated nodes using Session Manager. |                                   |                           |

## Topics

- [Turning on the advanced-instances tier](#)
- [Reverting from the advanced-instances tier to the standard-instances tier](#)

## Turning on the advanced-instances tier

AWS Systems Manager offers a standard-instances tier and an advanced-instances tier for non-EC2 machines in a [hybrid and multicloud](#) environment. The standard-instances tier lets you register a maximum of 1,000 hybrid-activated machines per AWS account per AWS Region. The advanced-instances tier is also required to use Patch Manager to patch Microsoft-released applications on non-EC2 nodes, and to connect to non-EC2 nodes using Session Manager. For more information, see [Turning on the advanced-instances tier](#).

This section describes how to configure your hybrid and multicloud environment to use the advanced-instances tier.

### Before you begin

Review pricing details for advanced instances. Advanced instances are available on a per-use-basis. For more information see, [AWS Systems Manager Pricing](#).

### Configuring permissions to turn on the advanced-instances tier

Verify that you have permission in AWS Identity and Access Management (IAM) to change your environment from the standard-instances tier to the advanced-instances tier. You must either have the AdministratorAccess IAM policy attached to your user, group, or role, or you must have permission to change the Systems Manager activation-tier service setting. The activation-tier setting uses the following API operations:

- [GetServiceSetting](#)
- [UpdateServiceSetting](#)

- [ResetServiceSetting](#)

Use the following procedure to add an inline IAM policy to a user account. This policy allows a user to view the current managed-instance tier setting. This policy also allows the user to change or reset the current setting in the specified AWS account and AWS Region.

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **Users**.
3. In the list, choose the name of the user to embed a policy in.
4. Choose the **Permissions** tab.
5. On the right side of the page, under **Permission policies**, choose **Add inline policy**.
6. Choose the **JSON** tab.
7. Replace the default content with the following:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ssm:GetServiceSetting"
      ],
      "Resource": "*"
    },
    {
      "Effect": "Allow",
      "Action": [
        "ssm:ResetServiceSetting",
        "ssm:UpdateServiceSetting"
      ],
      "Resource": "arn:aws:ssm:region:aws-account-id:servicesetting/ssm/managed-instance/activation-tier"
    }
  ]
}
```

8. Choose **Review policy**.

9. On the **Review policy** page, for **Name**, enter a name for the inline policy. For example: **Managed-Instances-Tier**.
10. Choose **Create policy**.

Administrators can specify read-only permission by assigning the following inline policy to the user.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ssm:GetServiceSetting"
      ],
      "Resource": "*"
    },
    {
      "Effect": "Deny",
      "Action": [
        "ssm:ResetServiceSetting",
        "ssm:UpdateServiceSetting"
      ],
      "Resource": "*"
    }
  ]
}
```

For more information about creating and editing IAM policies, see [Creating IAM Policies](#) in the *IAM User Guide*.

### Turning on the advanced-instances tier (console)

The following procedure shows you how to use the Systems Manager console to change *all* non-EC2 nodes that were added using managed-instance activation, in the specified AWS account and AWS Region, to use the advanced-instances tier.

#### Before you begin

Verify that the console is open in the AWS Region where you created your managed instances. You can switch Regions by using the list in the top, right corner of the console.

Verify that you have completed the setup requirements for your Amazon Elastic Compute Cloud (Amazon EC2) instances and non-EC2 machines in a [hybrid and multicloud](#) environment. For information, see [Setting up managed nodes for AWS Systems Manager](#).

### **Important**

The following procedure describes how to change an account-level setting. This change results in charges being billed to your account.

### **To turn on the advanced-instances tier (console)**

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Fleet Manager**.
3. Choose **Settings, Change Instance tier settings**.
4. Review the information in the dialog box about changing account settings, and then, and continue.
5. If you approve, choose the option to accept, and then choose **Change setting**.

The system can take several minutes to complete the process of moving all instances from the standard-instances tier to the advanced-instances tier.

### **Note**

For information about changing back to the standard-instances tier, see [Reverting from the advanced-instances tier to the standard-instances tier](#).

### **Turning on the advanced-instances tier (AWS CLI)**

The following procedure shows you how to use the AWS Command Line Interface to change *all* on-premises servers and VMs that were added using managed-instance activation, in the specified AWS account and AWS Region, to use the advanced-instances tier.

**⚠ Important**

The following procedure describes how to change an account-level setting. This change results in charges being billed to your account.

**To turn on the advanced-instances tier using the AWS CLI**

1. Open the AWS CLI and run the following command. Replace each *example resource placeholder* with your own information.

**Linux & macOS**

```
aws ssm update-service-setting \  
  --setting-id arn:aws:ssm:region:aws-account-id:servicesetting/ssm/managed-  
instance/activation-tier \  
  --setting-value advanced
```

**Windows**

```
aws ssm update-service-setting ^  
  --setting-id arn:aws:ssm:region:aws-account-id:servicesetting/ssm/managed-  
instance/activation-tier ^  
  --setting-value advanced
```

There is no output if the command succeeds.

2. Run the following command to view the current service settings for managed nodes in the current AWS account and AWS Region.

**Linux & macOS**

```
aws ssm get-service-setting \  
  --setting-id arn:aws:ssm:region:aws-account-id:servicesetting/ssm/managed-  
instance/activation-tier
```

**Windows**

```
aws ssm get-service-setting ^
```

```
--setting-id arn:aws:ssm:region:aws-account-id:servicesetting/ssm/managed-  
instance/activation-tier
```

The command returns information like the following.

```
{  
  "ServiceSetting": {  
    "SettingId": "/ssm/managed-instance/activation-tier",  
    "SettingValue": "advanced",  
    "LastModifiedDate": 1555603376.138,  
    "LastModifiedUser": "arn:aws:sts::123456789012:assumed-role/  
Administrator/User_1",  
    "ARN": "arn:aws:ssm:us-east-2:123456789012:servicesetting/ssm/managed-  
instance/activation-tier",  
    "Status": "PendingUpdate"  
  }  
}
```

## Turning on the advanced-instances tier (PowerShell)

The following procedure shows you how to use the AWS Tools for Windows PowerShell to change *all* on-premises servers and VMs that were added using managed-instance activation, in the specified AWS account and AWS Region, to use the advanced-instances tier.

### Important

The following procedure describes how to change an account-level setting. This change results in charges being billed to your account.

## To turn on the advanced-instances tier using PowerShell

1. Open AWS Tools for Windows PowerShell and run the following command. Replace each *example resource placeholder* with your own information.

```
Update-SSMServiceSetting `
  -SettingId "arn:aws:ssm:region:aws-account-id:servicesetting/ssm/managed-  
instance/activation-tier" `
  -SettingValue "advanced"
```

There is no output if the command succeeds.

2. Run the following command to view the current service settings for managed nodes in the current AWS account and AWS Region.

```
Get-SSMServiceSetting `
  -SettingId "arn:aws:ssm:region:aws-account-id:servicesetting/ssm/managed-
instance/activation-tier"
```

The command returns information like the following.

```
ARN:arn:aws:ssm:us-east-2:123456789012:servicesetting/ssm/managed-instance/
activation-tier
LastModifiedDate : 4/18/2019 4:02:56 PM
LastModifiedUser : arn:aws:sts::123456789012:assumed-role/Administrator/User_1
SettingId       : /ssm/managed-instance/activation-tier
SettingValue    : advanced
Status          : PendingUpdate
```

The system can take several minutes to complete the process of moving all nodes from the standard-instances tier to the advanced-instances tier.

#### Note

For information about changing back to the standard-instances tier, see [Reverting from the advanced-instances tier to the standard-instances tier](#).

## Reverting from the advanced-instances tier to the standard-instances tier

This section describes how to change hybrid-activated nodes running in the advanced-instances tier back to the standard-instances tier. This configuration applies to all hybrid-activated nodes in an AWS account and a single AWS Region.

### Before you begin

Review the following important details.

**Note**

- You can't revert back to the standard-instance tier if you're running more than 1,000 hybrid-activated nodes in the account and Region. You must first deregister nodes until you have 1,000 or fewer. This also applies to Amazon Elastic Compute Cloud (Amazon EC2) instances that use a Systems Manager hybrid activation (which isn't a common scenario). For more information, see [Deregistering managed nodes in a hybrid and multicloud environment](#).
- After you revert, you won't be able to use Session Manager, a capability of AWS Systems Manager, to interactively access your hybrid-activated nodes.
- After you revert, you won't be able to use Patch Manager, a capability of AWS Systems Manager, to patch applications released by Microsoft on hybrid-activated nodes.
- The process of reverting all hybrid-activated nodes back to the standard-instance tier can take 30 minutes or more to complete.

This section describes how to revert all hybrid-activated nodes in an AWS account and AWS Region from the advanced-instances tier to the standard-instances tier.

**Reverting to the standard-instances tier (console)**

The following procedure shows you how to use the Systems Manager console to change all hybrid-activated nodes in your [hybrid and multicloud](#) environment to use the standard-instances tier in the specified AWS account and AWS Region.

**To revert to the standard-instances tier (console)**

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Fleet Manager**.
3. Select the **Account settings** dropdown and choose **Instance tier settings**.
4. Choose **Change account setting**.
5. Review the information in the pop-up about changing account settings, and then if you approve, choose the option to accept and continue.

## Reverting to the standard-instances tier (AWS CLI)

The following procedure shows you how to use the AWS Command Line Interface to change all hybrid-activated nodes in your [hybrid and multicloud](#) environment to use the standard-instances tier in the specified AWS account and AWS Region.

### To revert to the standard-instances tier using the AWS CLI

1. Open the AWS CLI and run the following command. Replace each *example resource placeholder* with your own information.

#### Linux & macOS

```
aws ssm update-service-setting \  
  --setting-id arn:aws:ssm:region:aws-account-id:servicesetting/ssm/managed-  
instance/activation-tier \  
  --setting-value standard
```

#### Windows

```
aws ssm update-service-setting ^  
  --setting-id arn:aws:ssm:region:aws-account-id:servicesetting/ssm/managed-  
instance/activation-tier ^  
  --setting-value standard
```

There is no output if the command succeeds.

2. Run the following command 30 minutes later to view the settings for managed instances in the current AWS account and AWS Region.

#### Linux & macOS

```
aws ssm get-service-setting \  
  --setting-id arn:aws:ssm:region:aws-account-id:servicesetting/ssm/managed-  
instance/activation-tier
```

#### Windows

```
aws ssm get-service-setting ^
```

```
--setting-id arn:aws:ssm:region:aws-account-id:servicesetting/ssm/managed-  
instance/activation-tier
```

The command returns information like the following.

```
{  
  "ServiceSetting": {  
    "SettingId": "/ssm/managed-instance/activation-tier",  
    "SettingValue": "standard",  
    "LastModifiedDate": 1555603376.138,  
    "LastModifiedUser": "System",  
    "ARN": "arn:aws:ssm:us-east-2:123456789012:servicesetting/ssm/managed-  
instance/activation-tier",  
    "Status": "Default"  
  }  
}
```

The status changes to *Default* after the request has been approved.

## Reverting to the standard-instances tier (PowerShell)

The following procedure shows you how to use AWS Tools for Windows PowerShell to change hybrid-activated nodes in your hybrid and multicloud environment to use the standard-instances tier in the specified AWS account and AWS Region.

### To revert to the standard-instances tier using PowerShell

1. Open AWS Tools for Windows PowerShell and run the following command.

```
Update-SSMServiceSetting `
  -SettingId "arn:aws:ssm:region:aws-account-id:servicesetting/ssm/managed-  
instance/activation-tier" `
  -SettingValue "standard"
```

There is no output if the command succeeds.

2. Run the following command 30 minutes later to view the settings for managed instances in the current AWS account and AWS Region.

```
Get-SSMServiceSetting `
```

```
-SettingId "arn:aws:ssm:region:aws-account-id:servicesetting/ssm/managed-instance/activation-tier"
```

The command returns information like the following.

```
ARN: arn:aws:ssm:us-east-2:123456789012:servicesetting/ssm/managed-instance/activation-tier
LastModifiedDate : 4/18/2019 4:02:56 PM
LastModifiedUser : System
SettingId       : /ssm/managed-instance/activation-tier
SettingValue    : standard
Status         : Default
```

The status changes to *Default* after the request has been approved.

## Resetting passwords on managed nodes

You can reset the password for any user on a managed node. This includes Amazon Elastic Compute Cloud (Amazon EC2) instances; AWS IoT Greengrass core devices; and on-premises servers, edge devices, and virtual machines (VMs) that are managed by AWS Systems Manager. The password reset functionality is built on Session Manager, a capability of AWS Systems Manager. You can use this functionality to connect to managed nodes without opening inbound ports, maintaining bastion hosts, or managing SSH keys.

Password reset is useful when a user has forgotten a password, or when you want to quickly update a password without making an RDP or SSH connection to a managed node.

### Prerequisites

Before you can reset the password on a managed node, the following requirements must be met:

- The managed node on which you want to change a password must be a Systems Manager managed node. Also, SSM Agent version 2.3.668.0 or later must be installed on the managed node.) For information about installing or updating SSM Agent, see [Working with SSM Agent](#).
- The password reset functionality uses the Session Manager configuration that is set up for your account to connect to the managed node. Therefore, the prerequisites for using Session Manager must have been completed for your account in the current AWS Region. For more information, see [Setting up Session Manager](#).

**Note**

Session Manager support for on-premises nodes is provided for the advanced-instances tier only. For more information, see [Turning on the advanced-instances tier](#).

- The AWS user who is changing the password must have the `ssm:SendCommand` permission for the managed node. For more information, see [Restricting Run Command access based on tags](#).

## Restricting access

You can limit a user's ability to reset passwords to specific managed nodes. This is done by using identity-based policies for the Session Manager `ssm:StartSession` operation with the `AWS-PasswordReset` SSM document. For more information, see [Control user session access to instances](#).

## Encrypting data

Turn on AWS Key Management Service (AWS KMS) complete encryption for Session Manager data to use the password reset option for managed nodes. For more information, see [Turn on KMS key encryption of session data \(console\)](#).

## Reset a password on a managed node

You can reset a password on a Systems Manager managed node using the Systems Manager **Fleet Manager** console or the AWS Command Line Interface (AWS CLI).

### To change the password on a managed node (console)

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Fleet Manager**.
3. Choose the button next to the node that needs a new password.
4. Choose **Instance actions, Reset password**.
5. For **User name**, enter the name of the user for which you're changing the password. This can be any user name that has an account on the node.
6. Choose **Submit**.

7. Follow the prompts in the **Enter new password** command window to specify the new password.

 **Note**

If the version of SSM Agent on the managed node doesn't support password resets, you're prompted to install a supported version using Run Command, a capability of AWS Systems Manager.

### To reset the password on a managed node (AWS CLI)

1. To reset the password for a user on a managed node, run the following command. Replace each *example resource placeholder* with your own information.

 **Note**

To use the AWS CLI to reset a password, the Session Manager plugin must be installed on your local machine. For information, see [Install the Session Manager plugin for the AWS CLI](#).

### Linux & macOS

```
aws ssm start-session \  
  --target instance-id \  
  --document-name "AWS-PasswordReset" \  
  --parameters '{"username": [user-name]}'
```

### Windows

```
aws ssm start-session ^  
  --target instance-id ^  
  --document-name "AWS-PasswordReset" ^  
  --parameters username="user-name"
```

2. Follow the prompts in the **Enter new password** command window to specify the new password.

## Troubleshoot password resets on managed nodes

Many password reset issues can be resolved by ensuring that you have completed the [password reset prerequisites](#). For other problems, use the following information to help you troubleshoot password reset issues.

### Topics

- [Managed node not available](#)
- [SSM Agent not up-to-date \(console\)](#)
- [Password reset options aren't provided \(AWS CLI\)](#)
- [No authorization to run ssm:SendCommand](#)
- [Session Manager error message](#)

### Managed node not available

**Problem:** You want to reset the password for a managed node on the **Managed instances** console page, but the node isn't in the list.

- **Solution:** The managed node you want to connect to might not be configured for Systems Manager. To use an EC2 instance with Systems Manager, an AWS Identity and Access Management (IAM) instance profile that gives Systems Manager permission to perform actions on your instances must be attached to the instance. For information, see [Configure instance permissions required for Systems Manager](#).

To use a non-EC2 machine with Systems Manager, create an IAM service role that gives Systems Manager permission to perform actions on your managed nodes. For more information, see [Create the IAM service role required for Systems Manager in hybrid and multicloud environments](#). (Session Manager support for on-premises servers and VMs is provided for the advanced-instances tier only. For more information, see [Turning on the advanced-instances tier](#).)

### SSM Agent not up-to-date (console)

**Problem:** A message reports that the version of SSM Agent doesn't support password reset functionality.

- **Solution:** Version 2.3.668.0 or later of SSM Agent is required to perform password resets. In the console, you can update the agent on the managed node by choosing **Update SSM Agent**.

An updated version of SSM Agent is released whenever new capabilities are added to Systems Manager or updates are made to existing capabilities. Failing to use the latest version of the agent can prevent your managed node from using various Systems Manager capabilities and features. For that reason, we recommend that you automate the process of keeping SSM Agent up to date on your machines. For information, see [Automating updates to SSM Agent](#). Subscribe to the [SSM Agent Release Notes](#) page on GitHub to get notifications about SSM Agent updates.

### Password reset options aren't provided (AWS CLI)

**Problem:** You connect successfully to a managed node using the AWS CLI [start-session](#) command. You specified the SSM Document AWS-PasswordReset and provided a valid user name, but prompts to change the password aren't displayed.

- **Solution:** The version of SSM Agent on the managed node isn't up-to-date. Version 2.3.668.0 or later is required to perform password resets.

An updated version of SSM Agent is released whenever new capabilities are added to Systems Manager or updates are made to existing capabilities. Failing to use the latest version of the agent can prevent your managed node from using various Systems Manager capabilities and features. For that reason, we recommend that you automate the process of keeping SSM Agent up to date on your machines. For information, see [Automating updates to SSM Agent](#). Subscribe to the [SSM Agent Release Notes](#) page on GitHub to get notifications about SSM Agent updates.

### No authorization to run ssm:SendCommand

**Problem:** You attempt to connect to a managed node to change the password but receive an error message saying that you aren't authorized to run ssm:SendCommand on the managed node.

- **Solution:** Your IAM policy must include permission to run the ssm:SendCommand command. For information, see [Restricting Run Command access based on tags](#).

### Session Manager error message

**Problem:** You receive an error message related to Session Manager.

- **Solution:** Password reset support requires that Session Manager is configured correctly. For information, see [Setting up Session Manager](#) and [Troubleshooting Session Manager](#).

## Deregistering managed nodes in a hybrid and multicloud environment

If you no longer want to manage an on-premises server, edge device, or virtual machine (VM) by using AWS Systems Manager, then you can deregister it. Deregistering a hybrid-activated node removes it from the list of managed nodes in Systems Manager. AWS Systems Manager Agent (SSM Agent) running on the hybrid-activated node won't be able to refresh its authorization token because it's no longer registered. SSM Agent hibernates and reduce its ping frequency to Systems Manager in the cloud to once per hour.

You can reregister an on-premises server, edge device, or VM again at any time. Systems Manager stores the command history for a deregistered managed node for 30 days.

The following procedure describes how to deregister a hybrid-activated node by using the Systems Manager console. For information about how to do this by using the AWS Command Line Interface, see [deregister-managed-instance](#).

### To deregister a hybrid-activated node (console)

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Fleet Manager**.
3. Select the checkbox next to the managed node that you want to deregister.
4. Choose **Node actions, Tools, Deregister this managed node**.
5. Review the information in the **Deregister this managed node** dialog box. If you approve, choose **Deregister**.

### Working with OS file systems using Fleet Manager

You can use Fleet Manager, a capability of AWS Systems Manager, to work with the file system on your managed nodes. Using Fleet Manager, you can view information about the directory and file data stored on the volumes attached to your managed nodes. For example, you can view the name, size, extension, owner, and permissions for your directories and files. Up to 10,000 lines of file data can be previewed as text from the Fleet Manager console. You can also use this feature to `tail` files. When using `tail` to view file data, the last 10 lines of the file are displayed initially. As new lines of data are written to the file, the view is updated in real time. As a result, you can review log data from the console, which can improve the efficiency of your troubleshooting and systems administration. Additionally, you can create directories and copy, cut, paste, rename, or delete files and directories.

We recommend creating regular backups, or taking snapshots of the Amazon Elastic Block Store (Amazon EBS) volumes attached to your managed nodes. When copying, or cutting and pasting files, existing files and directories in the destination path with the same name as the new files or directories are replaced. Serious problems can occur if you replace or modify system files and directories. AWS doesn't guarantee that these problems can be solved. Modify system files at your own risk. You're responsible for all file and directory changes, and ensuring you have backups. Deleting or replacing files and directories can't be undone.

### Note

Fleet Manager uses Session Manager, a capability of AWS Systems Manager, to view text previews and `tail` files. For Amazon Elastic Compute Cloud (Amazon EC2) instances, the instance profile attached to your managed instances must provide permissions for Session Manager to use this feature. For more information about adding Session Manager permissions to an instance profile, see [Add Session Manager permissions to an existing IAM role](#). Also, AWS Key Management Service (AWS KMS) encryption must be turned on in your session preferences to use Fleet Manager features. For more information about enabling AWS KMS encryption for Session Manager, see [Turn on KMS key encryption of session data \(console\)](#).

## Topics

- [Viewing the OS file system using Fleet Manager](#)
- [Previewing OS files using Fleet Manager](#)
- [Tailing OS files using Fleet Manager](#)
- [Copying, cutting, and pasting OS files or directories using Fleet Manager](#)
- [Renaming OS files and directories using Fleet Manager](#)
- [Deleting OS files and directories using Fleet Manager](#)
- [Creating OS directories using Fleet Manager](#)
- [Cutting, copying, and pasting OS directories using Fleet Manager](#)

## Viewing the OS file system using Fleet Manager

You can use Fleet Manager to view the OS file system on a Systems Manager managed node.

## To view the file OS system using Fleet Manager

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Fleet Manager**.
3. Select the link of the managed node with the file system you want to view.
4. Choose **Tools, File system**.

## Previewing OS files using Fleet Manager

You can use Fleet Manager to preview text files on an OS.

### To view text previews of files using Fleet Manager

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Fleet Manager**.
3. Select the link of the managed node with the files you want to preview.
4. Choose **Tools, File system**.
5. Select the **File name** of the directory that contains the file you want to preview.
6. Choose the button next to the file whose content you want to preview.
7. Choose **Actions, Preview as text**.

## Tailing OS files using Fleet Manager

You can use Fleet Manager to tail a file on a managed node.

### To tail OS files with Fleet Manager

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Fleet Manager**.
3. Select the link of the managed node with the files you want to tail.
4. Choose **Tools, File system**.
5. Select the **File name** of the directory that contains the file you want to tail.
6. Choose the button next to the file whose content you want to tail.

## 7. Choose **Actions, Tail file**.

### Copying, cutting, and pasting OS files or directories using Fleet Manager

You can use Fleet Manager to copy, cut, and paste OS files on a managed node.

#### To copy or cut and paste files or directories using Fleet Manager

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Fleet Manager**.
3. Select the link of the managed node with the files you want to copy, or cut and paste.
4. Choose **Tools, File system**.
5. To copy or cut a file, select the **File name** of the directory that contains the file you want to copy or cut. To copy or cut a directory, choose the button next to the directory that you want to copy or cut and then proceed to step 8.
6. Choose the button next to the file you want to copy or cut.
7. In the **Actions** menu, choose **Copy** or **Cut**.
8. In the **File system** view, choose the button next to the directory you want to paste the file in.
9. In the **Actions** menu, choose **Paste**.

### Renaming OS files and directories using Fleet Manager

You can use Fleet Manager to rename files and directories on a managed node in your account.

#### To rename files or directories with Fleet Manager

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Fleet Manager**.
3. Select the link of the managed node with the files or directories you want to rename.
4. Choose **Tools, File system**.
5. To rename a file, select the **File name** of the directory that contains the file you want to rename. To rename a directory, choose the button next to the directory that you want to rename and then proceed to step 8.

6. Choose the button next to the file whose content you want to rename.
7. Choose **Actions, Rename**.
8. For **File name**, enter the new name for the file and select **Rename**.

## Deleting OS files and directories using Fleet Manager

You can use Fleet Manager to delete files and directories on a managed node in your account.

### To delete files or directories using Fleet Manager

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Fleet Manager**.
3. Select the link of the managed node with the files or directories you want to delete.
4. Choose **Tools, File system**.
5. To delete a file, select the **File name** of the directory that contains the file you want to delete. To delete a directory, choose the button next to the directory that you want to delete and then proceed to step 7.
6. Choose the button next to the file with the content you want to delete.
7. Choose **Actions, Delete**.

## Creating OS directories using Fleet Manager

You can use Fleet Manager to create directories on a managed node in your account.

### To create a directory using Fleet Manager

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Fleet Manager**.
3. Select the link of the managed node you want to create a directory in.
4. Choose **Tools, File system**.
5. Select the **File name** of the directory where you want to create a new directory.
6. Select **Create directory**.

7. For **Directory name**, enter the name for the new directory, and then select **Create directory**.

## Cutting, copying, and pasting OS directories using Fleet Manager

You can use Fleet Manager to cut, copy, and paste directories on a managed node in your account.

### To copy or cut and paste directories with Fleet Manager

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Fleet Manager**.
3. Select the link of the managed node with the files you want to copy, or cut and paste.
4. Choose **Tools, File system**.
5. Choose the button next to the directory that you want to copy or cut and then proceed to step 8.
6. In the **Actions** menu, choose **Copy** or **Cut**.
7. In the **File system** view, choose the button next to the directory you want to paste the file in.
8. In the **Actions** menu, choose **Paste**.

## Monitoring managed node performance

You can use Fleet Manager, a capability of AWS Systems Manager, to view performance data about your managed nodes in real time. The performance data is retrieved from performance counters.

The following performance counters are available in Fleet Manager:

- CPU utilization
- Disk input/output (I/O) utilization
- Network traffic
- Memory usage

### Note

Fleet Manager uses Session Manager, a capability of AWS Systems Manager, to retrieve performance data. For Amazon Elastic Compute Cloud (Amazon EC2) instances, the

instance profile attached to your managed instances must provide permissions for Session Manager to use this feature. For more information about adding Session Manager permissions to an instance profile, see [Add Session Manager permissions to an existing IAM role](#). Also, AWS Key Management Service (AWS KMS) encryption must be turned on in your session preferences to use Fleet Manager features. For more information about turning on AWS KMS encryption for Session Manager, see [Turn on KMS key encryption of session data \(console\)](#).

## To view performance data with Fleet Manager

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Fleet Manager**.
3. Choose the button next to the managed node whose performance you want to monitor.
4. Choose **View details**.
5. Choose **Tools, Performance counters**.

## Working with processes

You can use Fleet Manager, a capability of AWS Systems Manager, to work with processes on your managed nodes. Using Fleet Manager, you can view information about processes. For example, you can see the CPU utilization and memory usage of processes in addition to their handles and threads. With Fleet Manager, you can start and terminate processes from the console.

### Note

Fleet Manager uses Session Manager, a capability of AWS Systems Manager, to retrieve process data. For Amazon Elastic Compute Cloud (Amazon EC2) instances, the instance profile attached to your managed instances must provide permissions for Session Manager to use this feature. For more information about adding Session Manager permissions to an instance profile, see [Add Session Manager permissions to an existing IAM role](#). Also, AWS Key Management Service (AWS KMS) encryption must be turned on in your session preferences to use Fleet Manager features. For more information about turning on AWS KMS encryption for Session Manager, see [Turn on KMS key encryption of session data \(console\)](#).

## Topics

- [Viewing details about OS processes using Fleet Manager](#)
- [Starting an OS process on a managed node using Fleet Manager](#)
- [Terminating an OS process using Fleet Manager](#)

### Viewing details about OS processes using Fleet Manager

You can use Fleet Manager view details about processes on your managed nodes.

#### To view details about processes with Fleet Manager

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Fleet Manager**.
3. Select the link of the node whose processes you want to view.
4. Choose **Tools, Processes**.

### Starting an OS process on a managed node using Fleet Manager

You can use Fleet Manager to start a process on a managed node.

#### To start a process with Fleet Manager

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Fleet Manager**.
3. Select the link of the managed node you want to start a process on.
4. Choose **Tools, Processes**.
5. Select **Start new process**.
6. For **Process name or full path**, enter the name of the process or the full path to the executable.
7. (Optional) For **Working directory**, enter the directory path where you want the process to run.

## Terminating an OS process using Fleet Manager

### To terminate an OS process using Fleet Manager

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Fleet Manager**.
3. Select the link of the managed node you want to start a process on.
4. Choose **Tools, Processes**.
5. Choose the button next to the process you want to terminate.
6. Choose **Actions, Terminate process** or **Actions, Terminate process tree**.

#### Note

Terminating a process tree also terminates all processes and applications using that process.

### Viewing logs on managed nodes

You can use Fleet Manager, a capability of AWS Systems Manager, to view log data stored on your managed nodes. For Windows managed nodes, you can view Windows event logs and copy their details from the console. To help you search events, filter Windows event logs by **Event level**, **Event ID**, **Event source**, and **Time created**. You can also view other log data using the procedure to view the file system. For more information about viewing the file system with Fleet Manager, see [Working with OS file systems using Fleet Manager](#).

### To view Windows event logs with Fleet Manager

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Fleet Manager**.
3. Choose the button next to the managed node whose event logs you want to view.
4. Choose **View details**.
5. Choose **Tools, Windows event logs**.
6. Choose the **Log name** that contains the events you want to view.

7. Choose the button next to the **Log name** you want to view, and then select **View events**.
8. Choose the button next to the event you want to view, and then select **View event details**.
9. (Optional) Select **Copy as JSON** to copy the event details to your clipboard.

## Managing OS user accounts and groups on managed nodes using Fleet Manager

You can use Fleet Manager, a capability of AWS Systems Manager, to manage operating system (OS) user accounts and groups on your managed nodes. For example, you can create and delete users and groups. Additionally, you can view details like group membership, user roles, and status.

### Important

Fleet Manager uses Run Command and Session Manager, capabilities of AWS Systems Manager, for various user management operations. As a result, a user could grant permissions to an operating system user account that they would otherwise be unable to. This is because AWS Systems Manager Agent (SSM Agent) runs on Amazon Elastic Compute Cloud (Amazon EC2) instances using root permissions (Linux) or SYSTEM permissions (Windows Server). For more information about restricting access to root-level commands through SSM Agent, see [Restricting access to root-level commands through SSM Agent](#). To restrict access to this feature, we recommend creating AWS Identity and Access Management (IAM) policies for your users that only allow access to the actions you define. For more information about creating IAM policies for Fleet Manager, see [Controlling access to Fleet Manager](#).

## Topics

- [Creating an OS user or group using Fleet Manager](#)
- [Updating user or group membership using Fleet Manager](#)
- [Deleting an OS user or group using Fleet Manager](#)

## Creating an OS user or group using Fleet Manager

### Note

Fleet Manager uses Session Manager to set passwords for new users. For Amazon EC2 instances, the instance profile attached to your managed instances must provide

permissions for Session Manager to use this feature. For more information about adding Session Manager permissions to an instance profile, see [Add Session Manager permissions to an existing IAM role](#). Also, AWS Key Management Service (AWS KMS) encryption must be turned on in your session preferences to use Fleet Manager features. For more information about enabling AWS KMS encryption for Session Manager, see [Turn on KMS key encryption of session data \(console\)](#).

Instead of logging on directly to a server to create a user account or group, you can use the Fleet Manager console to perform the same tasks.

### To create an OS user account using Fleet Manager

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Fleet Manager**.
3. Choose the button next to the managed node you want to create a new user on.
4. Choose **View details**.
5. Choose **Tools, Users and groups**.
6. Choose the **Users** tab, and then choose **Create user**.
7. Enter a value for the **Name** of the new user.
8. (Recommended) Select the check box next to **Set password**. You will be prompted to provide a password for the new user at the end of the procedure.
9. Select **Create user**. If you selected the check box to create a password for the new user, you will be prompted to enter a value for the password and select **Done**. If the password you specify doesn't meet the requirements specified by your managed node's local or domain policies, an error is returned.

### To create an OS group using Fleet Manager

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Fleet Manager**.
3. Choose the button next to the managed node you want to create a group in.
4. Choose **View details**.

5. Choose **Tools, Users and groups**.
6. Choose the **Groups** tab, and then choose **Create group**.
7. Enter a value for the **Name** of the new group.
8. (Optional) Enter a value for the **Description** of the new group.
9. (Optional) Select users to add to the **Group members** for the new group.
10. Select **Create group**.

## Updating user or group membership using Fleet Manager

Instead of logging on directly to a server to update a user account or group, you can use the Fleet Manager console to perform the same tasks.

### To add an OS user account to a new group using Fleet Manager

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Fleet Manager**.
3. Choose the button next to the managed node where the user account exists that you want to update.
4. Choose **View details**.
5. Choose **Tools, Users and groups**.
6. Choose the **Users** tab.
7. Choose the button next to the user you want to update.
8. Choose **Actions, Add user to group**.
9. Choose the group you want to add the user to under **Add to group**.
10. Select **Add user to group**.

### To edit an OS group's membership using Fleet Manager

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Fleet Manager**.
3. Choose the button next to the managed node where the group exists that you want to update.
4. Choose **View details**.

5. Choose **Tools, Users and groups**.
6. Choose the **Groups** tab.
7. Choose the button next to the group you want to update.
8. Choose **Actions, Modify group**.
9. Choose the users you want to add or remove under **Group members**.
10. Select **Modify group**.

## Deleting an OS user or group using Fleet Manager

Instead of logging on directly to a server to delete a user account or group, you can use the Fleet Manager console to perform the same tasks.

### To delete an OS user account using Fleet Manager

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Fleet Manager**.
3. Choose the button next to the managed node where the user account exists that you want to delete.
4. Choose **View details**.
5. Choose **Users and groups**.
6. Choose the **Users** tab.
7. Choose the button next to the user you want to delete.
8. Choose **Actions, Delete local user**.

### To delete an OS group using Fleet Manager

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Fleet Manager**.
3. Choose the button next to the managed node where the group exists that you want to delete.
4. Choose **View details**.
5. Choose **Tools, Users and groups**.
6. Choose the **Group** tab.

7. Choose the button next to the group you want to update.
8. Choose **Actions, Delete local group**.

## Managing the Windows registry on managed nodes

You can use Fleet Manager, a capability of AWS Systems Manager, to manage the registry on your Windows Server managed nodes. From the Fleet Manager console you can create, copy, update, and delete registry entries and values.

### Important

We recommend creating a backup of the registry, or taking a snapshot of the root Amazon Elastic Block Store (Amazon EBS) volume attached to your managed node, before you modify the registry. Serious problems can occur if you modify the registry incorrectly. These problems might require you to reinstall the operating system, or restore the root volume of your node from a snapshot. AWS doesn't guarantee that these problems can be solved. Modify the registry at your own risk. You're responsible for all registry changes, and ensuring you have backups.

## Create a Windows registry key or entry

### To create a Windows registry key with Fleet Manager

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Fleet Manager**.
3. Choose the button next to the managed node you want to create a registry key on.
4. Choose **View details**.
5. Choose **Tools, Windows registry**.
6. Choose the hive you want to create a new registry key in by selecting the **Registry name**.
7. Choose **Create, Create registry key**.
8. Choose the button next to the registry entry you want to create a new key in.
9. Choose **Create registry key**.
10. Enter a value for the **Name** of the new registry key, and select **Submit**.

## To create a Windows registry entry with Fleet Manager

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Fleet Manager**.
3. Choose the button next to the instance you want to create a registry entry on.
4. Choose **View details**.
5. Choose **Tools, Windows registry**.
6. Choose the hive, and subsequent registry key you want to create a new registry entry in by selecting the **Registry name**.
7. Choose **Create, Create registry entry**.
8. Enter a value for the **Name** of the new registry entry.
9. Choose the **Type** of value you want to create for the registry entry. For more information about registry value types, see [Registry value types](#).
10. Enter a value for the **Value** of the new registry entry.

## Update a Windows registry entry

### To update a Windows registry entry with Fleet Manager

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Fleet Manager**.
3. Choose the button next to the managed node you want to update a registry entry on.
4. Choose **View details**.
5. Choose **Tools, Windows registry**.
6. Choose the hive, and subsequent registry key you want to update by selecting the **Registry name**.
7. Choose the button next to the registry entry you want to update.
8. Choose **Actions, Update registry entry**.
9. Enter the new value for the **Value** of the registry entry.
10. Choose **Update**.

## Delete a Windows registry entry or key

### To delete a Windows registry key with Fleet Manager

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Fleet Manager**.
3. Choose the button next to the managed node you want to delete a registry key on.
4. Choose **Tools, Windows registry**.
5. Choose the hive, and subsequent registry key you want to delete by selecting the **Registry name**.
6. Choose the button next to the registry key you want to delete.
7. Choose **Actions, Delete registry key**.

### To delete a Windows registry entry with Fleet Manager

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Fleet Manager**.
3. Choose the button next to the managed node you want to delete a registry entry on.
4. Choose **View details**.
5. Choose **Tools, Windows registry**.
6. Choose the hive, and subsequent registry key containing the entry you want to delete by selecting the **Registry name**.
7. Choose the button next to the registry entry you want to delete.
8. Choose **Actions, Delete registry entry**.

## Managing EC2 instances automatically with Default Host Management Configuration

The Default Host Management Configuration setting allows AWS Systems Manager to manage your Amazon EC2 instances automatically as *managed instances*. A managed instance is an EC2 instance that is configured for use with Systems Manager.

The benefits of managing your instances with Systems Manager include the following:

- Connect to your EC2 instances securely using Session Manager.
- Perform automated patch scans using Patch Manager.
- View detailed information about your instances using Systems Manager Inventory.
- Track and manage instances using Fleet Manager.
- Keep SSM Agent up to date automatically.

*Fleet Manager, Inventory, Patch Manager, and Session Manager are capabilities of Systems Manager.*

Default Host Management Configuration makes it possible to manage EC2 instances without your having to manually create an AWS Identity and Access Management (IAM) instance profile. Instead, Default Host Management Configuration creates and applies a default IAM role to ensure that Systems Manager has permissions to manage all instances in the AWS account and AWS Region where it's activated.

If the permissions provided aren't sufficient for your use case, you can also add policies to the default IAM role created by the Default Host Management Configuration. Alternatively, if you don't need permissions for all of the capabilities provided by the default IAM role, you can create your own custom role and policies. Any changes made to the IAM role you choose for Default Host Management Configuration applies to all managed Amazon EC2 instances in the Region and account.

For more information about the policy used by Default Host Management Configuration, see [AWS managed policy: AmazonSSMManagedEC2InstanceDefaultPolicy](#).

## Implement least privilege access

This procedures in this topic are intended to be performed only by administrators. Therefore, we recommend implementing *least privilege access* in order to prevent non-administrative users from configuring or modifying the Default Host Management Configuration. To view example policies that restrict access to the Default Host Management Configuration, see [Least privilege policy examples for Default Host Management Configuration](#) later in this topic.

### Important

Registration information for instances registered using Default Host Management Configuration is stored locally in the `var/lib/amazon/ssm` or `C:\ProgramData\Amazon` directories. Removing these directories or their files will prevent the instance

from acquiring the necessary credentials to connect to Systems Manager using Default Host Management Configuration. In these cases, you must use an IAM instance profile to provide the required permissions to your instance, or recreate the instance.

## Topics

- [Prerequisites](#)
- [Activating the Default Host Management Configuration setting](#)
- [Deactivating the Default Host Management Configuration setting](#)
- [Least privilege policy examples for Default Host Management Configuration](#)

## Prerequisites

In order to use Default Host Management Configuration in the AWS Region and AWS account where you activate the setting, the following requirements must be met.

- An instance to be managed must use Instance Metadata Service Version 2 (IMDSv2).

Default Host Management Configuration doesn't support Instance Metadata Service Version 1.

For information about transitioning to IMDSv2, see [Transition to using Instance Metadata Service Version 2](#) in the *Amazon EC2 User Guide*

- SSM Agent version 3.2.582.0 or later must be installed on the instance to be managed.

For information about checking the version of SSM Agent installed on your instance, see [Checking the SSM Agent version number](#).

For information about updating SSM Agent, see [Automatically updating SSM Agent](#).

- You, as the administrator performing the tasks in this topic, must have permissions for the [GetServiceSetting](#), [ResetServiceSetting](#), and [UpdateServiceSetting](#) API operations. Additionally, you must have permissions for the `iam:PassRole` permission for the `AWSSystemsManagerDefaultEC2InstanceManagementRole` IAM role. The following is an example policy providing these permissions. Replace each *example resource placeholder* with your own information.

```
{
  "Version": "2012-10-17",
  "Statement": [
```

```

    {
      "Effect": "Allow",
      "Action": [
        "ssm:GetServiceSetting",
        "ssm:ResetServiceSetting",
        "ssm:UpdateServiceSetting"
      ],
      "Resource": "arn:aws:ssm:region:account-id:servicesetting/ssm/managed-
instance/default-ec2-instance-management-role"
    },
    {
      "Effect": "Allow",
      "Action": [
        "iam:PassRole"
      ],
      "Resource": "arn:aws:iam::account-id:role/service-role/
AWSSystemsManagerDefaultEC2InstanceManagementRole",
      "Condition": {
        "StringEquals": {
          "iam:PassedToService": [
            "ssm.amazonaws.com"
          ]
        }
      }
    }
  ]
}

```

- If an IAM instance profile is already attached to an EC2 instance that is to be managed using Systems Manager, you must remove any permissions from it that allow the `ssm:UpdateInstanceInformation` operation. SSM Agent attempts to use instance profile permissions before using the Default Host Management Configuration permissions. If you allow the `ssm:UpdateInstanceInformation` operation in your own IAM instance profile, the instance will not use the Default Host Management Configuration permissions.

### Activating the Default Host Management Configuration setting

You can activate Default Host Management Configuration from the Fleet Manager console, or by using the AWS Command Line Interface or AWS Tools for Windows PowerShell.

You must turn on the Default Host Management Configuration one by one in each Region you where you want your Amazon EC2 instances managed by this setting.

After turning on Default Host Management Configuration, it might take up to 30 minutes for your instances to use the credentials of the role you choose in step 5 in the following procedure.

### To activate Default Host Management Configuration (console)

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Fleet Manager**.
3. Choose **Account management, Configure Default Host Management Configuration**.
4. Turn on **Enable Default Host Management Configuration**.
5. Choose the AWS Identity and Access Management (IAM) role used to enable Systems Manager capabilities for your instances. We recommend using the default role provided by Default Host Management Configuration. It contains the minimum set of permissions necessary to manage your Amazon EC2 instances using Systems Manager. If you prefer to use a custom role, the role's trust policy must allow Systems Manager as a trusted entity.
6. Choose **Configure** to complete setup.

### To activate Default Host Management Configuration (command line)

1. Create a JSON file on your local machine containing the following trust relationship policy.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "",
      "Effect": "Allow",
      "Principal": {
        "Service": "ssm.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

2. Open the AWS CLI or Tools for Windows PowerShell and run one of the following commands, depending on the operating system type of your local machine, to create a service role in your account. Replace each *example resource placeholder* with your own information.

## Linux & macOS

```
aws iam create-role \  
--role-name AWSSystemsManagerDefaultEC2InstanceManagementRole \  
--path /service-role/ \  
--assume-role-policy-document file://trust-policy.json
```

## Windows

```
aws iam create-role ^  
--role-name AWSSystemsManagerDefaultEC2InstanceManagementRole ^  
--path /service-role/ ^  
--assume-role-policy-document file://trust-policy.json
```

## PowerShell

```
New-IAMRole `\  
-RoleName "AWSSystemsManagerDefaultEC2InstanceManagementRole" `\  
-Path "/service-role/" `\  
-AssumeRolePolicyDocument "file://trust-policy.json"
```

3. Run the following command to attach the AmazonSSMManagedEC2InstanceDefaultPolicy managed policy to your newly created role. Replace each *example resource placeholder* with your own information.

## Linux & macOS

```
aws iam attach-role-policy \  
--policy-arn arn:aws:iam::aws:policy/AmazonSSMManagedEC2InstanceDefaultPolicy \  
--role-name AWSSystemsManagerDefaultEC2InstanceManagementRole
```

## Windows

```
aws iam attach-role-policy ^  
--policy-arn arn:aws:iam::aws:policy/AmazonSSMManagedEC2InstanceDefaultPolicy ^  
--role-name AWSSystemsManagerDefaultEC2InstanceManagementRole
```

## PowerShell

```
Register-IAMRolePolicy `
-PolicyArn "arn:aws:iam::aws:policy/AmazonSSMManagedEC2InstanceDefaultPolicy" `
-RoleName "AWSSystemsManagerDefaultEC2InstanceManagementRole"
```

4. Open the AWS CLI or Tools for Windows PowerShell and run the following command. Replace each *example resource placeholder* with your own information.

## Linux & macOS

```
aws ssm update-service-setting \
--setting-id arn:aws:ssm:region:account-id:servicesetting/ssm/managed-instance/
default-ec2-instance-management-role \
--setting-value service-role/AWSSystemsManagerDefaultEC2InstanceManagementRole
```

## Windows

```
aws ssm update-service-setting ^
--setting-id arn:aws:ssm:region:account-id:servicesetting/ssm/managed-instance/
default-ec2-instance-management-role ^
--setting-value service-role/AWSSystemsManagerDefaultEC2InstanceManagementRole
```

## PowerShell

```
Update-SSMServiceSetting `
-SettingId "arn:aws:ssm:region:account-id:servicesetting/ssm/managed-instance/
default-ec2-instance-management-role" `
-SettingValue "service-role/AWSSystemsManagerDefaultEC2InstanceManagementRole"
```

There is no output if the command succeeds.

5. Run the following command to view the current service settings for Default Host Management Configuration in the current AWS account and AWS Region.

## Linux & macOS

```
aws ssm get-service-setting \
```

```
--setting-id arn:aws:ssm:region:account-id:servicesetting/ssm/managed-instance/default-ec2-instance-management-role
```

## Windows

```
aws ssm get-service-setting ^  
--setting-id arn:aws:ssm:region:account-id:servicesetting/ssm/managed-instance/default-ec2-instance-management-role
```

## PowerShell

```
Get-SSMServiceSetting `   
-SettingId "arn:aws:ssm:region:account-id:servicesetting/ssm/managed-instance/default-ec2-instance-management-role"
```

The command returns information like the following.

```
{  
  "ServiceSetting": {  
    "SettingId": "/ssm/managed-instance/default-ec2-instance-management-role",  
    "SettingValue": "service-role/  
AWSSystemsManagerDefaultEC2InstanceManagementRole",  
    "LastModifiedDate": "2022-11-28T08:21:03.576000-08:00",  
    "LastModifiedUser": "System",  
    "ARN": "arn:aws:ssm:us-east-2:-123456789012:servicesetting/ssm/managed-instance/default-ec2-instance-management-role",  
    "Status": "Custom"  
  }  
}
```

## Deactivating the Default Host Management Configuration setting

You can deactivate Default Host Management Configuration from the Fleet Manager console, or by using the AWS Command Line Interface or AWS Tools for Windows PowerShell.

You must turn off the Default Host Management Configuration setting one by one in each Region where you no longer want your Amazon EC2 instances managed by this configuration. Deactivating it in one Region doesn't deactivate it in all Regions.

If you deactivate Default Host Management Configuration, and you have not attached an instance profile to your Amazon EC2 instances that allows access to Systems Manager, they will no longer be managed by Systems Manager.

### To deactivate Default Host Management Configuration (console)

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Fleet Manager**.
3. Choose **Account management, Default Host Management Configuration**.
4. Turn off **Enable Default Host Management Configuration**.
5. Choose **Configure** to disable Default Host Management Configuration.

### To deactivate Default Host Management Configuration (command line)

- Open the AWS CLI or Tools for Windows PowerShell and run the following command. Replace each *example resource placeholder* with your own information.

#### Linux & macOS

```
aws ssm reset-service-setting \  
--setting-id arn:aws:ssm:region:account-id:servicesetting/ssm/managed-instance/  
default-ec2-instance-management-role
```

#### Windows

```
aws ssm reset-service-setting ^  
--setting-id arn:aws:ssm:region:account-id:servicesetting/ssm/managed-instance/  
default-ec2-instance-management-role
```

#### PowerShell

```
Reset-SSMServiceSetting `  
-SettingId "arn:aws:ssm:region:account-id:servicesetting/ssm/managed-instance/  
default-ec2-instance-management-role"
```

## Least privilege policy examples for Default Host Management Configuration

The following sample policies demonstrate how to prevent members of your organization from making changes to the Default Host Management Configuration setting in your account.

### Service control policy for AWS Organizations

The following policy demonstrates how to prevent non-administrative members in your AWS Organizations from updating your Default Host Management Configuration setting. Replace each *example resource placeholder* with your own information.

```
{
  "Version": "2012-10-17",
  "Statement": [{
    "Effect": "Deny",
    "Action": [
      "ssm:UpdateServiceSetting",
      "ssm:ResetServiceSetting"
    ],
    "Resource": "arn:aws:ssm:*:*:servicesetting/ssm/managed-instance/default-ec2-instance-management-role",
    "Condition": {
      "StringNotEqualsIgnoreCase": {
        "aws:PrincipalTag/job-function": [
          "administrator"
        ]
      }
    }
  },
  {
    "Effect": "Deny",
    "Action": [
      "iam:PassRole"
    ],
    "Resource": "arn:aws:iam::*:role/service-role/AWSSystemsManagerDefaultEC2InstanceManagementRole",
    "Condition": {
      "StringEquals": {
        "iam:PassedToService": "ssm.amazonaws.com"
      },
      "StringNotEqualsIgnoreCase": {
        "aws:PrincipalTag/job-function": [
          "administrator"
        ]
      }
    }
  }
]
```

```

    ]
  }
}
},
{
  "Effect": "Deny",
  "Resource": "arn:aws:iam::*:role/service-role/
AWSSystemsManagerDefaultEC2InstanceManagementRole",
  "Action": [
    "iam:AttachRolePolicy",
    "iam>DeleteRole"
  ],
  "Condition": {
    "StringNotEqualsIgnoreCase": {
      "aws:PrincipalTag/job-function": [
        "administrator"
      ]
    }
  }
}
]
}
}
}

```

## Policy for IAM principals

The following policy demonstrates how to prevent IAM groups, roles, or users in your AWS Organizations from updating your Default Host Management Configuration setting. Replace each *example resource placeholder* with your own information.

```

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Deny",
      "Action": [
        "ssm:UpdateServiceSetting",
        "ssm:ResetServiceSetting"
      ],
      "Resource": "arn:aws:ssm:region:account-id:servicesetting/ssm/managed-
instance/default-ec2-instance-management-role"
    },
    {
      "Effect": "Deny",

```

```
        "Action": [
            "iam:AttachRolePolicy",
            "iam>DeleteRole",
            "iam:PassRole"
        ],
        "Resource": "arn:aws:iam::account-id:role/service-role/AWSSystemsManagerDefaultEC2InstanceManagementRole"
    }
}
```

## Connecting to a Windows Server managed instance using Remote Desktop

You can use Fleet Manager, a capability of AWS Systems Manager, to connect to your Windows Server Amazon Elastic Compute Cloud (Amazon EC2) instances using the Remote Desktop Protocol (RDP). Fleet Manager Remote Desktop, which is powered by [Amazon DCV](#), provides you with secure connectivity to your Windows Server instances directly from the Systems Manager console. You can have up to four simultaneous connections in a single browser window.

Currently, you can only use Remote Desktop with instances that are running Windows Server 2012 RTM or higher. Remote Desktop supports only English language inputs.

### Note

Fleet Manager Remote Desktop is a console-only service and doesn't support command-line connections to your managed instances. To connect to a Windows Server managed instance through a shell, you can use Session Manager, another capability of AWS Systems Manager. For more information, see [AWS Systems Manager Session Manager](#).

For information about configuring AWS Identity and Access Management (IAM) permissions to allow your instances to interact with Systems Manager, see [Configure instance permissions for Systems Manager](#).

## Topics

- [Setting up your environment](#)
- [Configuring IAM permissions for Remote Desktop](#)
- [Authenticating Remote Desktop connections](#)
- [Remote connection duration and concurrency](#)

- [Connect to a managed node using Remote Desktop](#)
- [Viewing information about current and completed connections](#)

## Setting up your environment

Before using Remote Desktop, verify that your environment meets the following requirements:

- **Managed node configuration**

Make sure that your Amazon EC2 instances are configured as [managed nodes](#) in Systems Manager.

- **SSM Agent minimum version**

Verify that nodes are running SSM Agent version 3.0.222.0 or higher. For information about how to check which agent version is running on a node, see [Checking the SSM Agent version number](#). For information about installing or updating SSM Agent, see [Working with SSM Agent](#).

- **RDP port configuration**

To accept remote connections, the Remote Desktop Services service on your Windows Server nodes must use default RDP port 3389. This is the default configuration on Amazon Machine Images (AMIs) provided by AWS. You are not explicitly required to open any inbound ports to use Remote Desktop.

- **PSReadLine module version for keyboard functionality**

To ensure that your keyboard functions properly in PowerShell, verify that nodes running Windows Server 2022 have PSReadLine module version 2.2.2 or higher installed. If they are running an older version, you can install the required version using the following commands.

```
Install-PackageProvider -Name NuGet -MinimumVersion 2.8.5.201 -Force
```

After the NuGet package provider is installed, run the following command.

```
Install-Module `
  -Name PSReadLine `
  -Repository PSGallery `
  -MinimumVersion 2.2.2 -Force
```

- **Session Manager configuration**

Before you can use Remote Desktop, you must complete the prerequisites for Session Manager setup. When you connect to an instance using Remote Desktop, any session preferences defined for your AWS account and AWS Region are applied. For more information, see [Setting up Session Manager](#).

 **Note**

If you log Session Manager activity using Amazon Simple Storage Service (Amazon S3), then your Remote Desktop connections will generate the following error in `bucket_name/Port/stderr`. This error is expected behavior and can be safely ignored.

```
Setting up data channel with id SESSION_ID failed: failed to create websocket
for datachannel with error: CreateDataChannel failed with no output or
error: createDataChannel request failed: unexpected response from the service
<BadRequest>
<ClientErrorMessage>Session is already terminated</ClientErrorMessage>
</BadRequest>
```

## Configuring IAM permissions for Remote Desktop

In addition to the required IAM permissions for Systems Manager and Session Manager, the user or role you use must be allowed permissions for initiating connections.

### Permissions for initiating connections

To make RDP connections to EC2 instances in the console, the following permissions are required:

- `ssm-guiconnect:CancelConnection`
- `ssm-guiconnect:GetConnection`
- `ssm-guiconnect:StartConnection`

### Permissions for listing connections

In order to view lists of connections in the console, the following permission is required:

`ssm-guiconnect:ListConnections`

The following are example IAM policies that you can attach to a user or role to allow different types of interaction with Remote Desktop. Replace each *example resource placeholder* with your own information.

### Standard policy for connecting to EC2 instances

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "EC2",
      "Effect": "Allow",
      "Action": [
        "ec2:DescribeInstances",
        "ec2:GetPasswordData"
      ],
      "Resource": "*"
    },
    {
      "Sid": "SSM",
      "Effect": "Allow",
      "Action": [
        "ssm:DescribeInstanceProperties",
        "ssm:GetCommandInvocation",
        "ssm:GetInventorySchema"
      ],
      "Resource": "*"
    },
    {
      "Sid": "TerminateSession",
      "Effect": "Allow",
      "Action": [
        "ssm:TerminateSession"
      ],
      "Resource": "*",
      "Condition": {
        "StringLike": {
          "ssm:resourceTag/aws:ssmmessages:session-id": [
            "${aws:userid}"
          ]
        }
      }
    }
  ],
}
```

```

    {
      "Sid": "SSMStartSession",
      "Effect": "Allow",
      "Action": [
        "ssm:StartSession"
      ],
      "Resource": [
        "arn:aws:ec2:*:account-id:instance/*",
        "arn:aws:ssm:*:account-id:managed-instance/*",
        "arn:aws:ssm:*::document/AWS-StartPortForwardingSession"
      ],
      "Condition": {
        "ForAnyValue:StringEquals": {
          "aws:CalledVia": "ssm-guiconnect.amazonaws.com"
        }
      }
    },
    {
      "Sid": "GuiConnect",
      "Effect": "Allow",
      "Action": [
        "ssm-guiconnect:CancelConnection",
        "ssm-guiconnect:GetConnection",
        "ssm-guiconnect:StartConnection",
        "ssm-guiconnect:ListConnections"
      ],
      "Resource": "*"
    }
  ]
}

```

## Policy for connecting to EC2 instances with specific tags

### Note

In the following IAM policy, the `SSMStartSession` section requires an Amazon Resource Name (ARN) for the `ssm:StartSession` action. As shown, the ARN you specify does *not* require an AWS account ID. If you specify an account ID, Fleet Manager returns an `AccessDeniedException`.

The `AccessTaggedInstances` section, which is located lower in the example policy, also requires ARNs for `ssm:StartSession`. For those ARNs, you do specify AWS account IDs.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "EC2",
      "Effect": "Allow",
      "Action": [
        "ec2:DescribeInstances",
        "ec2:GetPasswordData"
      ],
      "Resource": "*"
    },
    {
      "Sid": "SSM",
      "Effect": "Allow",
      "Action": [
        "ssm:DescribeInstanceProperties",
        "ssm:GetCommandInvocation",
        "ssm:GetInventorySchema"
      ],
      "Resource": "*"
    },
    {
      "Sid": "SSMStartSession",
      "Effect": "Allow",
      "Action": [
        "ssm:StartSession"
      ],
      "Resource": [
        "arn:aws:ssm:*::document/AWS-StartPortForwardingSession"
      ],
      "Condition": {
        "ForAnyValue:StringEquals": {
          "aws:CalledVia": "ssm-guiconnect.amazonaws.com"
        }
      }
    },
    {
      "Sid": "AccessTaggedInstances",
      "Effect": "Allow",
      "Action": [
        "ssm:StartSession"
      ],
    },
  ]
}
```

```

    "Resource": [
      "arn:aws:ec2:*:account-id:instance/*",
      "arn:aws:ssm:*:account-id:managed-instance/*"
    ],
    "Condition": {
      "StringLike": {
        "ssm:resourceTag/tag key": [
          "tag value"
        ]
      }
    }
  },
  {
    "Sid": "GuiConnect",
    "Effect": "Allow",
    "Action": [
      "ssm-guiconnect:CancelConnection",
      "ssm-guiconnect:GetConnection",
      "ssm-guiconnect:StartConnection",
      "ssm-guiconnect:ListConnections"
    ],
    "Resource": "*"
  }
]
}

```

## Policy for AWS IAM Identity Center users to connect to EC2 instances

```

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "SSO",
      "Effect": "Allow",
      "Action": [
        "sso:ListDirectoryAssociations*",
        "identitystore:DescribeUser"
      ],
      "Resource": "*"
    },
    {
      "Sid": "EC2",
      "Effect": "Allow",

```

```

    "Action": [
      "ec2:DescribeInstances",
      "ec2:GetPasswordData"
    ],
    "Resource": "*"
  },
  {
    "Sid": "SSM",
    "Effect": "Allow",
    "Action": [
      "ssm:DescribeInstanceProperties",
      "ssm:GetCommandInvocation",
      "ssm:GetInventorySchema"
    ],
    "Resource": "*"
  },
  {
    "Sid": "TerminateSession",
    "Effect": "Allow",
    "Action": [
      "ssm:TerminateSession"
    ],
    "Resource": "*",
    "Condition": {
      "StringLike": {
        "ssm:resourceTag/aws:ssmmessages:session-id": [
          "${aws:userName}"
        ]
      }
    }
  },
  {
    "Sid": "SSMStartSession",
    "Effect": "Allow",
    "Action": [
      "ssm:StartSession"
    ],
    "Resource": [
      "arn:aws:ec2:*:*:instance/*",
      "arn:aws:ssm:*:*:managed-instance/*",
      "arn:aws:ssm:*:*:document/AWS-StartPortForwardingSession"
    ],
    "Condition": {
      "ForAnyValue:StringEquals": {

```

```

        "aws:CalledVia": "ssm-guiconnect.amazonaws.com"
    }
}
},
{
    "Sid": "SSMSendCommand",
    "Effect": "Allow",
    "Action": [
        "ssm:SendCommand"
    ],
    "Resource": [
        "arn:aws:ec2:*:*:instance/*",
        "arn:aws:ssm:*:*:managed-instance/*",
        "arn:aws:ssm:*:*:document/AWSSSO-CreateSSOUser"
    ]
},
{
    "Sid": "GuiConnect",
    "Effect": "Allow",
    "Action": [
        "ssm-guiconnect:CancelConnection",
        "ssm-guiconnect:GetConnection",
        "ssm-guiconnect:StartConnection",
        "ssm-guiconnect:ListConnections"
    ],
    "Resource": "*"
}
]
}

```

## Authenticating Remote Desktop connections

When establishing a remote connection, you can authenticate using Windows credentials or the Amazon EC2 key pair (.pem file) that is associated with the instance. For information about using key pairs, see [Amazon EC2 key pairs and Windows instances](#) in the *Amazon EC2 User Guide*.

Alternatively, if you're authenticated to the AWS Management Console using AWS IAM Identity Center, you can connect to your instances without providing additional credentials. For an example of a policy to allow remote connection authentication using IAM Identity Center, see [Configuring IAM permissions for Remote Desktop](#).

## Before you begin

Note the following conditions for using IAM Identity Center authentication before you begin connecting using Remote Desktop.

- Remote Desktop supports IAM Identity Center authentication for nodes in the same AWS Region where you enabled IAM Identity Center.
- Remote Desktop supports IAM Identity Center user names of up to 16 characters.
- Remote Desktop supports IAM Identity Center user names consisting of alphanumeric characters and the following special characters: . - \_

### Important

Connections won't succeed for IAM Identity Center user names that contain the following characters: + = ,

IAM Identity Center supports these characters in user names, but Fleet Manager RDP connections do not.

In addition, if an IAM Identity Center user name contains one or more @ symbols, Fleet Manager disregards the first @ symbol and all characters that follow it, whether or not the @ introduces the domain portion of an email address. For instance, for the IAM Identity Center user name `diego_ramirez@example.com`, the `@example.com` portion is ignored and the user name for Fleet Manager becomes `diego_ramirez`. For `diego_r@mirez@example.com`, Fleet Manager disregards `@mirez@example.com`, and the username for Fleet Manager becomes `diego_r`.

- When a connection is authenticated using IAM Identity Center, Remote Desktop creates a local Windows user in the instance's Local Administrators group. This user persists after the remote connection has ended.
- Remote Desktop does not allow IAM Identity Center authentication for nodes that are Microsoft Active Directory domain controllers.
- Although Remote Desktop allows you to use IAM Identity Center authentication for nodes *joined* to an Active Directory domain, we do not recommend doing so. This authentication method grants administrative permissions to users which might override more restrictive permissions granted by the domain.

## Supported Regions for IAM Identity Center authentication

Remote Desktop connections using IAM Identity Center authentication are supported in the following AWS Regions:

- US East (Ohio) (us-east-2)
- US East (N. Virginia) (us-east-1)
- US West (N. California) (us-west-1)
- US West (Oregon) (us-west-2)
- Africa (Cape Town) (af-south-1)
- Asia Pacific (Hong Kong) (ap-east-1)
- Asia Pacific (Mumbai) (ap-south-1)
- Asia Pacific (Tokyo) (ap-northeast-1)
- Asia Pacific (Seoul) (ap-northeast-2)
- Asia Pacific (Osaka) (ap-northeast-3)
- Asia Pacific (Singapore) (ap-southeast-1)
- Asia Pacific (Sydney) (ap-southeast-2)
- Asia Pacific (Jakarta) (ap-southeast-3)

### **Remote connection duration and concurrency**

The following conditions apply to active Remote Desktop connections:

- **Connection duration**

By default, a Remote Desktop connection is disconnected after 60 minutes. To prevent a connection from being disconnected, you can choose **Renew session** before being disconnected to reset the duration timer.

- **Connection timeout**

A Remote Desktop connection disconnects after it has been idle for more than 10 minutes.

- **Concurrent connections**

By default, you can have a maximum of 5 active Remote Desktop connections at one time for the same AWS account and AWS Region. To request a service quota increase of up to 25 concurrent connections, see [Requesting a quota increase](#) in the *Service Quotas User Guide*.

## Connect to a managed node using Remote Desktop

### Browser copy/paste support for text

Using the Google Chrome and Microsoft Edge browsers, you can copy and paste text from a managed node to your local machine, and from your local machine to a managed node that you are connected to.

Using the Mozilla Firefox browser, you can copy and paste text from a managed node to your local machine only. Copying from your local machine to the managed node is not supported.

### To connect to a managed node using Fleet Manager Remote Desktop

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Fleet Manager**.
3. Choose the node that you want to connect to. You can select either the check box or the node name.
4. On the **Node actions** menu, choose **Connect with Remote Desktop**.
5. Choose your preferred **Authentication type**. If you choose **User credentials**, enter the user name and password for a Windows user account on the node that you're connecting to. If you choose **Key pair**, you can provide authentication using one of the following methods:

- a. Choose **Browse local machine** if you want to select the PEM key associated with your instance from your local file system.  
  
- or -
  - b. Choose **Paste key pair content** if you want to copy the contents of the PEM file and paste them in to the provided field.
6. Select **Connect**.
  7. To choose your preferred display resolution, in the **Actions** menu, choose **Resolutions**, and then select from the following:
    - **Adapt Automatically**
    - **1920 x 1080**
    - **1400 x 900**
    - **1366 x 768**
    - **800 x 600**

The **Adapt Automatically** option sets the resolution based on your detected screen size.

## Viewing information about current and completed connections

You can use the Fleet Manager section of the Systems Manager console to view information about RDP connections that have been made in your account. Using a set of filters, you can limit the list of connections displayed to a time range, a specific instance, the user who made the connections, and connections of a specific status. The console also provides tabs that show information about all currently active connections, and all past connections.

### To view information about current and completed connections

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Fleet Manager**.
3. Choose **Account management, Connect with Remote Desktop**.
4. Choose one of the following tabs:
  - **Active connections**

- **Connection history**

5. To further narrow the list of connection results displayed, specify one or more filters in the search

box. You can also enter a free-text search term.

## Managing Amazon EBS volumes on managed instances

[Amazon Elastic Block Store](#) (Amazon EBS) provides block level storage volumes for use with Amazon Elastic Compute Cloud (EC2) instances. EBS volumes behave like raw, unformatted block devices. You can mount these volumes as devices on your instances.

You can use Fleet Manager, a capability of AWS Systems Manager, to manage Amazon EBS volumes on your managed instances. For example, you can initialize an EBS volume, format a partition, and mount the volume to make it available for use.

### Note

Fleet Manager currently supports Amazon EBS volume management for Windows Server instances only.

## View EBS volume details

### To view details for an EBS volume with Fleet Manager

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Fleet Manager**.
3. Choose the button next to the managed instance for which you want to view EBS volume details.
4. Choose **View details**.
5. Choose **Tools, EBS volumes**.
6. To view details for an EBS volume, choose its ID in the **Volume ID** column.

## Initialize and format an EBS volume

### To initialize and format an EBS volume with Fleet Manager

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Fleet Manager**.
3. Choose the button next to the managed instance for which you want to initialize, format, and mount an EBS volume. You can only initialize an EBS volume if its disk is empty.
4. Choose **View details**.
5. In the **Tools** menu, choose **EBS volumes**.
6. Choose the button next to the EBS volume you want to initialize and format.
7. Choose **Initialize and format**.
8. In **Partition style**, choose the partition style you want to use for the EBS volume.
9. (Optional) Choose a **Drive letter** for the partition.
10. (Optional) Enter a **Partition name** to identify the partition.
11. Choose the **File system** to use to organize files and data stored in the partition.
12. Choose **Confirm** to make the EBS volume available for use. You can't change the partition configuration from the AWS Management Console after confirming, however, you can use SSH or RDP to log into the instance to change the partition configuration.

## Accessing the Red Hat Knowledge base portal

You can use Fleet Manager, a capability of AWS Systems Manager, to access the Knowledge base portal if you are a Red Hat customer. You are considered a Red Hat customer if you run Red Hat Enterprise Linux (RHEL) instances or use RHEL services on AWS. The Knowledge base portal includes binaries, and knowledge-share and discussion forums for community support that are available only to Red Hat licensed customers.

In addition to the required AWS Identity and Access Management (IAM) permissions for Systems Manager and Fleet Manager, the user or role you use to access the console must allow the `rhe1kb:GetRhe1URL` action to access the Knowledge base portal.

## To access the Red Hat Knowledgebase Portal

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Fleet Manager**.
3. Choose the RHEL instance you want to use to connect to the Red Hat Knowledgebase Portal.
4. Choose **Account management, Access Red Hat Knowledgebase** to open the Red Hat Knowledge base page.

If you use RHEL on AWS to run fully supported RHEL workloads, you can also access the Red Hat Knowledge base through Red Hat's website by using your AWS credentials.

## Troubleshooting managed node availability

For several AWS Systems Manager capabilities like Run Command, Distributor, and Session Manager, you can choose to manually select the managed nodes on which you want to run an operation. In cases like these, after you specify that you want to choose nodes manually, the system displays a list of managed nodes where you can run the operation.

This topic provides information to help you diagnose why a managed node *that you have confirmed is running* isn't included in your lists of managed nodes in Systems Manager.

In order for a node to be managed by Systems Manager and available in lists of managed nodes, it must meet three requirements:

- SSM Agent must be installed and running on the node with a supported operating system.

### Note

Some AWS managed Amazon Machine Images (AMIs) are configured to launch instances with [SSM Agent](#) preinstalled. (You can also configure a custom AMI to preinstall SSM Agent.) For more information, see [Find AMIs with the SSM Agent preinstalled](#).

- For Amazon Elastic Compute Cloud (Amazon EC2) instances, you must attach an AWS Identity and Access Management (IAM) instance profile to the instance. The instance profile enables the instance to communicate with the Systems Manager service. If you don't assign an instance profile to the instance, you register it using a [hybrid activation](#), which is not a common scenario.

- SSM Agent must be able to connect to a Systems Manager endpoint in order to register itself with the service. Thereafter, the managed node must be available to the service, which is confirmed by the service sending a signal every five minutes to check the instance's health.
- After the status of a managed node has been `Connection Lost` for at least 30 days, the node might no longer be listed in the Fleet Manager console. To restore it to the list, the issue that caused the lost connection must be resolved.

After you verify that a managed node is running, you can use the following command to check whether SSM Agent successfully registered with the Systems Manager service. This command doesn't return results until a successful registration has taken place.

### Linux & macOS

```
aws ssm describe-instance-associations-status \  
  --instance-id instance-id
```

### Windows

```
aws ssm describe-instance-associations-status ^  
  --instance-id instance-id
```

### PowerShell

```
Get-SSMInstanceAssociationsStatus `  
  -InstanceId instance-id
```

If registration was successful and the managed node is now available for Systems Manager operations, the command returns results similar to the following.

```
{  
  "InstanceAssociationStatusInfos": [  
    {  
      "AssociationId": "fa262de1-6150-4a90-8f53-d7eb5EXAMPLE",  
      "Name": "AWS-GatherSoftwareInventory",  
      "DocumentVersion": "1",  
      "AssociationVersion": "1",  
      "InstanceId": "i-02573cafcfEXAMPLE",  
      "Status": "Pending",
```

```
    "DetailedStatus": "Associated"
  },
  {
    "AssociationId": "f9ec7a0f-6104-4273-8975-82e34EXAMPLE",
    "Name": "AWS-RunPatchBaseline",
    "DocumentVersion": "1",
    "AssociationVersion": "1",
    "InstanceId": "i-02573cafcfEXAMPLE",
    "Status": "Queued",
    "AssociationName": "SystemAssociationForScanningPatches"
  }
]
```

If registration hasn't completed yet or was unsuccessful, the command returns results similar to the following:

```
{
  "InstanceAssociationStatusInfos": []
}
```

If the command doesn't return results after 5 minutes or so, use the following information to help you troubleshoot problems with your managed nodes.

## Topics

- [Solution 1: Verify that SSM Agent is installed and running on the managed node](#)
- [Solution 2: Verify that an IAM instance profile has been specified for the instance \(EC2 instances only\)](#)
- [Solution 3: Verify service endpoint connectivity](#)
- [Solution 4: Verify target operating system support](#)
- [Solution 5: Verify you're working in the same AWS Region as the Amazon EC2 instance](#)
- [Solution 6: Verify the proxy configuration you applied to SSM Agent on your managed node](#)
- [Solution 7: Install a TLS certificate on managed instances](#)
- [Troubleshooting managed node availability using ssm-cli](#)

## Solution 1: Verify that SSM Agent is installed and running on the managed node

Make sure the latest version of SSM Agent is installed and running on the managed node.

To determine whether SSM Agent is installed and running on a managed node, see [Checking SSM Agent status and starting the agent](#).

To install or reinstall SSM Agent on a managed node, see the following topics:

- [Manually installing and uninstalling SSM Agent on EC2 instances for Linux](#)
- [How to install the SSM Agent on hybrid Linux nodes](#)
- [Manually installing and uninstalling SSM Agent on EC2 instances for Windows Server](#)
- [How to install the SSM Agent on hybrid Windows nodes](#)

### **Solution 2: Verify that an IAM instance profile has been specified for the instance (EC2 instances only)**

For Amazon Elastic Compute Cloud (Amazon EC2) instances, verify that the instance is configured with an AWS Identity and Access Management (IAM) instance profile that allows the instance to communicate with the Systems Manager API. Also verify that your user has an IAM trust policy that allows your user to communicate with the Systems Manager API.

#### **Note**

On-premises servers, edge devices, and virtual machines (VMs) use an IAM service role instead of an instance profile. For more information, see [Create the IAM service role required for Systems Manager in hybrid and multicloud environments](#).

### **To determine whether an instance profile with the necessary permissions is attached to an EC2 instance**

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances**.
3. Choose the instance to check for an instance profile.
4. On the **Description** tab in the bottom pane, locate **IAM role** and choose the name of the role.
5. On the role **Summary** page for the instance profile, on the **Permissions** tab, ensure that `AmazonSSMManagedInstanceCore` is listed under **Permissions policies**.

If a custom policy is used instead, ensure that it provides the same permissions as `AmazonSSMManagedInstanceCore`.

## [Open AmazonSSMManagedInstanceCore in the console](#)

For information about other policies that can be attached to an instance profile for Systems Manager, see [Configure instance permissions required for Systems Manager](#).

### **Solution 3: Verify service endpoint connectivity**

Verify that the instance has connectivity to the Systems Manager service endpoints. This connectivity is provided by creating and configuring VPC endpoints for Systems Manager, or by allowing HTTPS (port 443) outbound traffic to the service endpoints.

For Amazon EC2 instances, the Systems Manager service endpoint for the AWS Region is used to register the instance if your virtual private cloud (VPC) configuration allows outbound traffic. However, if the VPC configuration the instance was launched in does not allow outbound traffic and you can't change this configuration to allow connectivity to the public service endpoints, you must configure interface endpoints for your VPC instead.

For more information, see [Improve the security of EC2 instances by using VPC endpoints for Systems Manager](#).

### **Solution 4: Verify target operating system support**

Verify that the operation you have chosen can be run on the type of managed node you expect to see listed. Some Systems Manager operations can target only Windows instances or only Linux instances. For example, the Systems Manager (SSM) documents `AWS-InstallPowerShellModule` and `AWS-ConfigureCloudWatch` can be run only on Windows instances. In the **Run a command** page, if you choose either of these documents and select **Choose instances manually**, only your Windows instances are listed and available for selection.

### **Solution 5: Verify you're working in the same AWS Region as the Amazon EC2 instance**

Amazon EC2 instances are created and available in specific AWS Regions, such as the US East (Ohio) Region (us-east-2) or Europe (Ireland) Region (eu-west-1). Ensure that you're working in the same AWS Region as the Amazon EC2 instance that you want to work with. For more information, see [Choosing a Region](#) in *Getting Started with the AWS Management Console*.

### **Solution 6: Verify the proxy configuration you applied to SSM Agent on your managed node**

Verify that the proxy configuration you applied to SSM Agent on your managed node is correct. If the proxy configuration is incorrect, the node can't connect to the required service endpoints, or

Systems Manager might identify the operating system of the managed node incorrectly. For more information, see [Configuring SSM Agent to use a proxy on Linux nodes](#) and [Configure SSM Agent to use a proxy for Windows Server instances](#).

### Solution 7: Install a TLS certificate on managed instances

A Transport Layer Security (TLS) certificate must be installed on each managed instance you use with AWS Systems Manager. AWS services use these certificates to encrypt calls to other AWS services.

A TLS certificate is already installed by default on each Amazon EC2 instance created from any Amazon Machine Image (AMI). Most modern operating systems include the required TLS certificate from Amazon Trust Services CAs in their trust store.

To verify whether the required certificate is installed on your instance run the following command based on the operating system of your instance. Be sure to replace the *region* portion of the URL with the AWS Region where your managed instance is located.

#### Linux & macOS

```
curl -L https://ssm.region.amazonaws.com
```

#### Windows

```
Invoke-WebRequest -Uri https://ssm.region.amazonaws.com
```

The command should return an `UnknownOperationException` error. If you receive an SSL/TLS error message instead then the required certificate might not be installed.

If you find the required Amazon Trust Services CA certificates aren't installed on your base operating systems, on instances created from AMIs that aren't supplied by Amazon, or on your own on-premises servers and VMs, you must install and allow a certificate from [Amazon Trust Services](#), or use AWS Certificate Manager (ACM) to create and manage certificates for a supported integrated service.

Each of your managed instances must have one of the following Transport Layer Security (TLS) certificates installed.

- Amazon Root CA 1

- Starfield Services Root Certificate Authority - G2
- Starfield Class 2 Certificate Authority

For information about using ACM, see the [AWS Certificate Manager User Guide](#).

If certificates in your computing environment are managed by a Group Policy Object (GPO), then you might need to configure Group Policy to include one of these certificates.

For more information about the Amazon Root and Starfield certificates, see the blog post [How to Prepare for AWS's Move to Its Own Certificate Authority](#).

## Troubleshooting managed node availability using `ssm-cli`

The `ssm-cli` is a standalone command line tool included in the SSM Agent installation. When you install SSM Agent 3.1.501.0 or later on a machine, you can run `ssm-cli` commands on that machine. The output of those commands helps you determine whether the machine meets the minimum requirements for an Amazon EC2 instance or non-EC2 machine to be managed by AWS Systems Manager, and therefore added to lists of managed nodes in Systems Manager. (SSM Agent version 3.1.501.0 was released in November, 2021.)

### Minimum requirements

For an Amazon EC2 instance or non-EC2 machine to be managed by AWS Systems Manager, and available in lists of managed nodes, it must meet three primary requirements:

- SSM Agent must be installed and running on a machine with a [supported operating system](#).

Some AWS managed Amazon Machine Images (AMIs) for EC2 are configured to launch instances with [SSM Agent](#) preinstalled. (You can also configure a custom AMI to preinstall SSM Agent.) For more information, see [Find AMIs with the SSM Agent preinstalled](#).

- An AWS Identity and Access Management (IAM) instance profile (for EC2 instances) or IAM service role (for non-EC2 machines) that supplies the required permissions to communicate with the Systems Manager service must be attached to the machine.
- SSM Agent must be able to connect to a Systems Manager endpoint to register itself with the service. Thereafter, the managed node must be available to the service, which is confirmed by the service sending a signal every five minutes to check the managed node's health.

### Preconfigured commands in `ssm-cli`

Preconfigured commands are included that gather the required information to help you diagnose why a machine that you have confirmed is running isn't included in your lists of managed nodes in Systems Manager. These commands are run when you specify the `get-diagnostics` option.

On the machine, run the following command to use `ssm-cli` to help you troubleshoot managed node availability.

## Linux & macOS

```
ssm-cli get-diagnostics --output table
```

## Windows

On Windows Server machines, you must navigate to the `C:\Program Files\Amazon\SSM` directory before running the command.

```
ssm-cli.exe get-diagnostics --output table
```

## PowerShell

On Windows Server machines, you must navigate to the `C:\Program Files\Amazon\SSM` directory before running the command.

```
.\ssm-cli.exe get-diagnostics --output table
```

The command returns output as a table similar to the following.

### Note

Connectivity checks to the `ssmmessages`, `s3`, `kms`, `logs`, and `monitoring` endpoints are for additional optional features such as Session Manager that can log to Amazon Simple Storage Service (Amazon S3) or Amazon CloudWatch Logs, and use AWS Key Management Service (AWS KMS) encryption.

## Linux & macOS

```
[root@instance]# ssm-cli get-diagnostics --output table
```

```

```

The following table provides additional details for each of the checks performed by `ssm-cli`.

### ssm-cli diagnostic checks

| Check                                | Details  |
|--------------------------------------|--|
| Amazon EC2 instance metadata service | Indicates whether the managed node is able to reach the metadata service. A failed test indicates a connectivity issue to <code>http://169.254.169.254</code> which can be caused by local route, proxy, or operating system (OS) firewall and proxy configurations. |
| Hybrid instance registration         | Indicates whether SSM Agent is registered using a hybrid activation.   |
| Connectivity to ssm endpoint         | Indicates whether the node is able to reach the service endpoints for Systems Manager on TCP port 443. A failed test   |

| Check   | Details   |
|---|---|
|   | <p>indicates connectivity issues to <code>https://ssm.<i>region</i>.amazonaws.com</code> depending on the AWS Region where the node is located. Connectivity issues can be caused by the VPC configuration including security groups, network access control lists, route tables, or OS firewalls and proxies.</p>  |
| Connectivity to <code>ec2messages</code> endpoint | <p>Indicates whether the node is able to reach the service endpoints for Systems Manager on TCP port 443. A failed test indicates connectivity issues to <code>https://ec2messages.<i>region</i>.amazonaws.com</code> depending on the AWS Region where the node is located. Connectivity issues can be caused by the VPC configuration including security groups, network access control lists, route tables, or OS firewalls and proxies.</p> |
| Connectivity to <code>ssmmessages</code> endpoint | <p>Indicates whether the node is able to reach the service endpoints for Systems Manager on TCP port 443. A failed test indicates connectivity issues to <code>https://ssmmessages.<i>region</i>.amazonaws.com</code> depending on the AWS Region where the node is located. Connectivity issues can be caused by the VPC configuration including security groups, network access control lists, route tables, or OS firewalls and proxies.</p> |

| Check                         | Details  |
|-------------------------------|--|
| Connectivity to s3 endpoint   | Indicates whether the node is able to reach the service endpoint for Amazon Simple Storage Service on TCP port 443. A failed test indicates connectivity issues to <code>https://s3.<i>region</i>.amazonaws.com</code> depending on the AWS Region where the node is located. Connectivity to this endpoint is not required for a node to appear in your managed nodes list. |
| Connectivity to kms endpoint  | Indicates whether the node is able to reach the service endpoint for AWS Key Management Service on TCP port 443. A failed test indicates connectivity issues to <code>https://kms.<i>region</i>.amazonaws.com</code> depending on the AWS Region where the node is located. Connectivity to this endpoint is not required for a node to appear in your managed nodes list.   |
| Connectivity to logs endpoint | Indicates whether the node is able to reach the service endpoint for Amazon CloudWatch Logs on TCP port 443. A failed test indicates connectivity issues to <code>https://logs.<i>region</i>.amazonaws.com</code> depending on the AWS Region where the node is located. Connectivity to this endpoint is not required for a node to appear in your managed nodes list.      |

| Check                               | Details  |
|-------------------------------------|--|
| Connectivity to monitoring endpoint | Indicates whether the node is able to reach the service endpoint for Amazon CloudWatch on TCP port 443. A failed test indicates connectivity issues to <code>https://monitoring.<i>region</i>.amazonaws.com</code> depending on the AWS Region where the node is located. Connectivity to this endpoint is not required for a node to appear in your managed nodes list. |
| AWS Credentials                     | Indicates whether SSM Agent has the required credentials based on the IAM instance profile (for EC2 instances) or IAM service role (for non-EC2 machines) attached to the machine. A failed test indicates that no IAM instance profile or IAM service role is attached to the machine, or it does not contain the required permissions for Systems Manager.             |
| Agent service                       | Indicates whether SSM Agent service is running, and whether the service is running as root for Linux or macOS, or SYSTEM for Windows Server. A failed test indicates SSM Agent service is not running or is not running as root or SYSTEM.   |
| Proxy configuration                 | Indicates whether SSM Agent is configured to use a proxy.  |
| Sysprep image state (Windows only)  | Indicates the state of Sysprep on the node. SSM Agent will not start on the node if the Sysprep state is a value other than <code>IMAGE_STATE_COMPLETE</code> .  |
| SSM Agent version                   | Indicates whether the latest available version of SSM Agent is installed.  |

# AWS Systems Manager Compliance

You can use Compliance, a capability of AWS Systems Manager, to scan your fleet of managed nodes for patch compliance and configuration inconsistencies. You can collect and aggregate data from multiple AWS accounts and Regions, and then drill down into specific resources that aren't compliant. By default, Compliance displays current compliance data about patching in Patch Manager and associations in State Manager. (Patch Manager and State Manager are also both capabilities of AWS Systems Manager.) To get started with Compliance, open the [Systems Manager console](#). In the navigation pane, choose **Compliance**.

Patch compliance data from Patch Manager can be sent to AWS Security Hub. Security Hub gives you a comprehensive view of your high-priority security alerts and compliance status. It also monitors the patching status of your fleet. For more information, see [Integrating Patch Manager with AWS Security Hub](#).

Compliance offers the following additional benefits and features:

- View compliance history and change tracking for Patch Manager patching data and State Manager associations by using AWS Config.
- Customize Compliance to create your own compliance types based on your IT or business requirements.
- Remediate issues by using Run Command, another capability of AWS Systems Manager, State Manager, or Amazon EventBridge.
- Port data to Amazon Athena and Amazon QuickSight to generate fleet-wide reports.

## EventBridge support

This Systems Manager capability is supported as an *event* type in Amazon EventBridge rules. For information, see [Monitoring Systems Manager events with Amazon EventBridge](#) and [Reference: Amazon EventBridge event patterns and types for Systems Manager](#).

## Chef InSpec integration

Systems Manager integrates with [Chef InSpec](#). InSpec is an open-source, runtime framework that allows you to create human-readable profiles on GitHub or Amazon Simple Storage Service (Amazon S3). You can then use Systems Manager to run compliance scans and view compliant and noncompliant managed nodes. For more information, see [Using Chef InSpec profiles with Systems Manager Compliance](#).

## Pricing

Compliance is offered at no additional charge. You only pay for the AWS resources that you use.

## Contents

- [Getting started with Compliance](#)

## Getting started with Compliance

To get started with Compliance, a capability of AWS Systems Manager, complete the following tasks.

| Task  | For more information  |
|---|---|
| <p>Compliance works with patch data in Patch Manager and associations in State Manager. (Patch Manager and State Manager are also both capabilities of AWS Systems Manager.)</p> <p>Compliance also works with custom compliance types on managed nodes that are managed using Systems Manager. Verify that you have completed the setup requirements for your Amazon Elastic Compute Cloud (Amazon EC2) instances and non-EC2 machines in a <a href="#">hybrid and multicloud</a> environment.</p> | <p><a href="#">Setting up Systems Manager unified console for an organization</a></p> |
| <p>Update Systems Manager SSM Agent (SSM Agent) on your managed nodes to the latest version.</p>  | <p><a href="#">Working with SSM Agent</a></p>   |
| <p>If you plan to monitor patch compliance, verify that you've configured Patch Manager.</p>  | <p><a href="#">AWS Systems Manager Patch Manager</a></p>                              |

| Task  | For more information   |
|---|--|
| You must perform patching operations by using Patch Manager before Compliance can display patch compliance data.  |  |
| If you plan to monitor association compliance, verify that you've created State Manager associations. You must create associations before Compliance can display association compliance data. | <a href="#">AWS Systems Manager State Manager</a>                            |
| (Optional) Configure the system to view compliance history and change tracking.   | <a href="#">Viewing compliance configuration history and change tracking</a> |
| (Optional) Create custom compliance types.  | <a href="#">Assign custom compliance metadata using the AWS CLI</a>          |
| (Optional) Create a resource data sync to aggregate all compliance data in a target Amazon Simple Storage Service (Amazon S3) bucket.   | <a href="#">Creating a resource data sync for Compliance</a>                 |

## Creating a resource data sync for Compliance

You can use the resource data sync feature in AWS Systems Manager to send compliance data from all of your managed nodes to a target Amazon Simple Storage Service (Amazon S3) bucket. When you create the sync, you can specify managed nodes from multiple AWS accounts, AWS Regions, and your [hybrid and multicloud](#) environment. Resource data sync then automatically updates the centralized data when new compliance data is collected. With all compliance data stored in a target S3 bucket, you can use services like Amazon Athena and Amazon QuickSight to query and analyze the aggregated data. Configuring resource data sync for Compliance is a one-time operation.

Use the following procedure to create a resource data sync for Compliance by using the AWS Management Console.

### To create and configure an S3 bucket for resource data sync (console)

1. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.

2. Create a bucket to store your aggregated compliance data. For more information, see [Create a Bucket](#) in the *Amazon Simple Storage Service User Guide*. Make a note of the bucket name and the AWS Region where you created it.
3. Open the bucket, choose the **Permissions** tab, and then choose **Bucket Policy**.
4. Copy and paste the following bucket policy into the policy editor. Replace `amzn-s3-demo-bucket` and `Account-ID` with the name of the S3 bucket you created and a valid AWS account ID. Optionally, replace `Bucket-Prefix` with the name of an Amazon S3 prefix (subdirectory). If you didn't create a prefix, remove `Bucket-Prefix/` from the ARN in the policy.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "SSMBucketPermissionsCheck",
      "Effect": "Allow",
      "Principal": {
        "Service": "ssm.amazonaws.com"
      },
      "Action": "s3:GetBucketAcl",
      "Resource": "arn:aws:s3:::amzn-s3-demo-bucket"
    },
    {
      "Sid": "SSMBucketDelivery",
      "Effect": "Allow",
      "Principal": {
        "Service": "ssm.amazonaws.com"
      },
      "Action": "s3:PutObject",
      "Resource": ["arn:aws:s3:::amzn-s3-demo-bucket/Bucket-Prefix/*/*",
accountid=Account_ID_number/*"],
      "Condition": {
        "StringEquals": {
          "s3:x-amz-acl": "bucket-owner-full-control"
        }
      }
    }
  ]
}
```

## To create a resource data sync

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Fleet Manager**.
3. Choose **Account management, Resource Data Syncs**, and then choose **Create resource data sync**.
4. In the **Sync name** field, enter a name for the sync configuration.
5. In the **Bucket name** field, enter the name of the Amazon S3 bucket you created at the start of this procedure.
6. (Optional) In the **Bucket prefix** field, enter the name of an S3 bucket prefix (subdirectory).
7. In the **Bucket region** field, choose **This region** if the S3 bucket you created is located in the current AWS Region. If the bucket is located in a different AWS Region, choose **Another region**, and enter the name of the Region.

### Note

If the sync and the target S3 bucket are located in different Regions, you might be subject to data transfer pricing. For more information, see [Amazon S3 Pricing](#).

8. Choose **Create**.

## Learn details about Compliance

Compliance, a capability of AWS Systems Manager, collects and reports data about the status of patching in Patch Manager patching and associations in State Manager. (Patch Manager and State Manager are also both capabilities of AWS Systems Manager.) Compliance also reports on custom compliance types you have specified for your managed nodes. This section includes details about each of these compliance types and how to view Systems Manager compliance data. This section also includes information about how to view compliance history and change tracking.

### Note

Systems Manager integrates with [Chef InSpec](#). InSpec is an open-source, runtime framework that allows you to create human-readable profiles on GitHub or Amazon Simple Storage Service (Amazon S3). Then you can use Systems Manager to run compliance scans

and view compliant and noncompliant instances. For more information, see [Using Chef InSpec profiles with Systems Manager Compliance](#).

## About patch compliance

After you use Patch Manager to install patches on your instances, compliance status information is immediately available to you in the console or in response to AWS Command Line Interface (AWS CLI) commands or corresponding Systems Manager API operations.

For information about patch compliance status values, see [Patch compliance state values](#).

## About State Manager association compliance

After you create one or more State Manager associations, compliance status information is immediately available to you in the console or in response to AWS CLI commands or corresponding Systems Manager API operations. For associations, Compliance shows statuses of Compliant or Non-compliant and the severity level assigned to the association, such as Critical or Medium.

## About custom compliance

You can assign compliance metadata to a managed node. This metadata can then be aggregated with other compliance data for compliance reporting purposes. For example, say that your business runs versions 2.0, 3.0, and 4.0 of software X on your managed nodes. The company wants to standardize on version 4.0, meaning that instances running versions 2.0 and 3.0 are non-compliant. You can use the [PutComplianceItems](#) API operation to explicitly note which managed nodes are running older versions of software X. You can only assign compliance metadata by using the AWS CLI, AWS Tools for Windows PowerShell, or the SDKs. The following CLI sample command assigns compliance metadata to a managed instance and specifies the compliance type in the required format Custom:. Replace each *example resource placeholder* with your own information.

### Linux & macOS

```
aws ssm put-compliance-items \  
  --resource-id i-1234567890abcdef0 \  
  --resource-type ManagedInstance \  
  --compliance-type Custom:SoftwareXCheck \  
  --execution-summary ExecutionTime=AnyStringToDenoteTimeOrDate \  
  --items  
  Id=Version2.0,Title=SoftwareXVersion,Severity=CRITICAL,Status=NON_COMPLIANT
```

## Windows

```
aws ssm put-compliance-items ^
  --resource-id i-1234567890abcdef0 ^
  --resource-type ManagedInstance ^
  --compliance-type Custom:SoftwareXCheck ^
  --execution-summary ExecutionTime=AnyStringToDenoteTimeOrDate ^
  --items
  Id=Version2.0,Title=SoftwareXVersion,Severity=CRITICAL,Status=NON_COMPLIANT
```

### Note

The ResourceType parameter only supports ManagedInstance. If you add custom compliance to a managed AWS IoT Greengrass core device, you must specify a ResourceType of ManagedInstance.

Compliance managers can then view summaries or create reports about which managed nodes are or aren't compliant. You can assign a maximum of 10 different custom compliance types to a managed node.

For an example of how to create a custom compliance type and view compliance data, see [Assign custom compliance metadata using the AWS CLI](#).

## Viewing current compliance data

This section describes how to view compliance data in the Systems Manager console and by using the AWS CLI. For information about how to view patch and association compliance history and change tracking, see [Viewing compliance configuration history and change tracking](#).

### Topics

- [Viewing current compliance data \(console\)](#)
- [Viewing current compliance data \(AWS CLI\)](#)

## Viewing current compliance data (console)

Use the following procedure to view compliance data in the Systems Manager console.

## To view current compliance reports in the Systems Manager console

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Compliance**.
3. In the **Compliance dashboard filtering** section, choose an option to filter compliance data. The **Compliance resources summary** section displays counts of compliance data based on the filter you chose.
4. To drill down into a resource for more information, scroll down to the **Details overview for resources** area and choose the ID of a managed node.
5. On the **Instance ID** or **Name** details page, choose the **Configuration compliance** tab to view a detailed configuration compliance report for the managed node.

### Note

For information about fixing compliance issues, see [Remediating compliance issues using EventBridge](#).

## Viewing current compliance data (AWS CLI)

You can view summaries of compliance data for patching, associations, and custom compliance types in the in the AWS CLI by using the following AWS CLI commands.

### [list-compliance-summaries](#)

Returns a summary count of compliant and non-compliant association statuses according to the filter you specify. (API: [ListComplianceSummaries](#))

### [list-resource-compliance-summaries](#)

Returns a resource-level summary count. The summary includes information about compliant and non-compliant statuses and detailed compliance-item severity counts, according to the filter criteria you specify. (API: [ListResourceComplianceSummaries](#))

You can view additional compliance data for patching by using the following AWS CLI commands.

## [describe-patch-group-state](#)

Returns high-level aggregated patch compliance state for a patch group. (API: [DescribePatchGroupState](#))

## [describe-instance-patch-states-for-patch-group](#)

Returns the high-level patch state for the instances in the specified patch group. (API: [DescribeInstancePatchStatesForPatchGroup](#))

### Note

For an illustration of how to configure patching and view patch compliance details by using the AWS CLI, see [Tutorial: Patch a server environment using the AWS CLI](#).

## Viewing compliance configuration history and change tracking

Systems Manager Compliance displays *current* patching and association compliance data for your managed nodes. You can view patching and association compliance history and change tracking by using [AWS Config](#). AWS Config provides a detailed view of the configuration of AWS resources in your AWS account. This includes how the resources are related to one another and how they were configured in the past so that you can see how the configurations and relationships change over time. To view patching and association compliance history and change tracking, you must turn on the following resources in AWS Config:

- SSM:PatchCompliance
- SSM:AssociationCompliance

For information about how to choose and configure these specific resources in AWS Config, see [Selecting Which Resources AWS Config Records](#) in the *AWS Config Developer Guide*.

### Note

For information about AWS Config pricing, see [Pricing](#).

## Deleting a resource data sync for Compliance

If you no longer want to use AWS Systems Manager Compliance to view compliance data, then we also recommend deleting resource data syncs used for Compliance data collection.

### To delete a Compliance resource data sync

1. Open the AWS Systems Manager console at <https://console.aws.amazon.com/systems-manager/>.
2. In the navigation pane, choose **Fleet Manager**.
3. Choose **Account management, Resource data syncs**.
4. Choose a sync in the list.

#### **Important**

Make sure you choose the sync used for Compliance. Systems Manager supports resource data sync for multiple capabilities. If you choose the wrong sync, you could disrupt data aggregation for Systems Manager Explorer or Systems Manager Inventory.

5. Choose **Delete**.
6. Delete the Amazon Simple Storage Service (Amazon S3) bucket where the data was stored. For information about deleting an S3 bucket, see [Deleting a bucket](#).

## Remediating compliance issues using EventBridge

You can quickly remediate patch and association compliance issues by using Run Command, a capability of AWS Systems Manager. You can target instance or AWS IoT Greengrass core device IDs or tags and run the `AWS-RunPatchBaseline` document or the `AWS-RefreshAssociation` document. If refreshing the association or re-running the patch baseline fails to resolve the compliance issue, then you need to investigate your associations, patch baselines, or instance configurations to understand why the Run Command operations didn't resolve the problem.

For more information about patching, see [AWS Systems Manager Patch Manager](#) and [SSM Command document for patching: AWS-RunPatchBaseline](#).

For more information about associations, see [Working with associations in Systems Manager](#).

For more information about running a command, see [AWS Systems Manager Run Command](#).

## Specify Compliance as the target of an EventBridge event

You can also configure Amazon EventBridge to perform an action in response to Systems Manager Compliance events. For example, if one or more managed nodes fail to install Critical patch updates or run an association that installs anti-virus software, then you can configure EventBridge to run the `AWS-RunPatchBaseline` document or the `AWS-RefreshAssociation` document when the Compliance event occurs.

Use the following procedure to configure Compliance as the target of an EventBridge event.

### To configure Compliance as the target of a EventBridge event (console)

1. Open the Amazon EventBridge console at <https://console.aws.amazon.com/events/>.
2. In the navigation pane, choose **Rules**.
3. Choose **Create rule**.
4. Enter a name and description for the rule.

A rule can't have the same name as another rule in the same AWS Region and on the same event bus.

5. For **Event bus**, choose the event bus that you want to associate with this rule. If you want this rule to respond to matching events that come from your own AWS account, select **default**. When an AWS service in your account emits an event, it always goes to your account's default event bus.
6. For **Rule type**, choose **Rule with an event pattern**.
7. Choose **Next**.
8. For **Event source**, choose **AWS events or EventBridge partner events**.
9. In the **Event pattern** section, choose **Event pattern form**.
10. For **Event source**, choose **AWS services**.
11. For **AWS service**, choose **Systems Manager**.
12. For **Event type**, choose **Configuration Compliance**.
13. For **Specific detail type(s)**, choose **Configuration Compliance State Change**.
14. Choose **Next**.
15. For **Target types**, choose **AWS service**.
16. For **Select a target**, choose **Systems Manager Run Command**.

17. In the **Document** list, choose a Systems Manager document (SSM document) to run when your target is invoked. For example, choose `AWS-RunPatchBaseline` for a non-compliant patch event, or choose `AWS-RefreshAssociation` for a non-compliant association event.
18. Specify information for the remaining fields and parameters.

**Note**

Required fields and parameters have an asterisk (\*) next to the name. To create a target, you must specify a value for each required parameter or field. If you don't, the system creates the rule, but the rule won't be run.

19. Choose **Next**.
20. (Optional) Enter one or more tags for the rule. For more information, see [Tagging Your Amazon EventBridge Resources](#) in the *Amazon EventBridge User Guide*.
21. Choose **Next**.
22. Review the details of the rule and choose **Create rule**.

## Assign custom compliance metadata using the AWS CLI
