### ABSTRACT

When operating at LP5, the G160M wavecal exposures will need to occur at LP2 due to light leaking through the FCA at 5.5". As such, we need to investigate if there are systematic effects introduced by obtaining science at LP5 and wavecal exposures at LP2, that would affect the wavelength calibration for G160M when operating at LP5. With that goal in mind, this program is designed to determine whether there is movement on the

Proposal 16052 (STScI Edit Number: 0, Created: Thursday, November 7, 2019 at 1:01:23 PM Eastern Standard Time) - Overview  
detector in the dispersion (x) or cross-dispersion direction (y) when moving the aperture between LP2 and LP5.

The basic design of the program is to obtain a series of lamp flashes at LP2 and LP5 on the detector, emulating how G160M operations could potentially occur at LP5 if wavecal cannot be taken concurrently with the science exposures. At each LP, we perform 5x50s lampflashes before moving to the next LP. Each LP will be sampled 5 times. The spectra will then cross-correlated to assess changes in pixel space to check for aperture shift and/or drift in x-dispersion and dispersion direction.

### **OBSERVING DESCRIPTION**

The aperture is moved between LP2 and LP5 five times. Each time, the wavecal lamp is flashed for 50s every 200s. This will allow us to investigate the existence of shift/drift in the dispersion and cross-dispersion direction due to movement of the COS aperture.

From program 16006 we know that WCA FUVA G160M/1577 can be operated at LP5 (+5.4") without light leak

All lamp exposures to be taken with G160M/1577/FUVA, FP-POS=4 and the default lamp setting (LAMP = PtNe1 with current = Medium)

In order to minimize the amount of OSM drift, we start the program with a lamp image using mirror A (i.e. engaging the OSM position at NCM1 before we move to G160M). We do this because OSM drift studies have shown that the settling time for OSM drift is shorter when the OSM mechanism moves from NCM1->G160M compared to G130M->G160M. Then, in order to isolate shift/drift due to aperture movement \*only\*, the program takes a long lamp exposure at LP2 for t=2000s using 50s flashes every 200s, to allow OSM1 to fully settle. There are no OSM movements in subsequent exposures, with all G160M/1577/FUVA exposures taken at the LP2 focus.

Program design:

- (1) Lamp image with mirror A to move OSM mechanism to NCM1
- (2) Settling exposure at LP2
- (3) LP2 lampflash exposure
- (4) Aperture move to LP5
- (5) LP5 lampflash exposure
- (6) Aperture move to LP2
- (7) Repeat (2)-(5) 4 times.

Exposure times:

-50s gives peak counts of 20-50 in G160M/FUVA lines which are ~0.4-1 cnts/s

-Flash sequence of 50s on every 200s (50:150, on:off) is consistent with 1:3 on:off lamp flash ratio deemed safe for temperature offset between the lamp and the chamber.

XSTEPS qesiparms are needed, with the relative move between one exposure and the next.

All the exposures have LIFETIME-POSITION = LP2

In order for us to accurately test for drift due to aperture movement, it is essential that the exposures after an aperture movement are not interrupted. As such, aperture movements and the exposure following an aperture movement are inside a non-interruptible sequence to facilitate visit scheduling around SAA interruptions.

>>> Please note that SQL will be needed to by-pass calibration. <<<
